THE *Daily Mail's* proposal of a flotilla of electric launches for the Thames river service is eminently feasible. Both from an engineering and from a commercial point of view, its successful accomplishment is well within the bounds of possibility. Indeed, this is a form of locomotion in which the secondary battery has many special advantages in competition with steam. For a river traffic like that on the Thames a frequent and rapid service of boats is essential; it is preferable to have a large number of small boats than a smaller number of larger dimensions, because of the nature of the competition with the parallel road and rail traffic. Small river launches driven by steam are essentially inefficient. Small electric launches, capable of carrying, say, from 100 to 150 passengers, are as efficient as would be electric launches of much larger dimensions, and are far more efficient than steam. They would also be more manageable than electric launches of larger size. The life of storage cells is much greater in river service than in road vehicles, as the injury due to mechanical shocks and vibration is almost if not quite absent. The only vibration the cells might be subjected to would be in moving them into and out of the launches for the charging operations, as it would probably be found impracticable to charge them *in situ*. Trucks of cells, however, could be conveniently wheeled on to the launches at the various stopping places, and the act of placing them in position on board could readily be made to complete their electrical connection, as is done, for example, on the Birmingham battery system. We trust the scheme will receive the attention it merits from the London County Council.

American Institute of Electrical Engineers.—At the annual meeting, held on May 16th, Mr. Carl Hering was elected president of the Institute for the forthcoming year.

German Atlantic Cable.—The laying of the Emden-Fayal section of this cable was completed last Saturday. A Reuter telegram states that the first experiments made on Wednesday between Emden and Horta, Azores, "were satisfactory beyond expectation."

Extension of the City and South London Railway to Clapham.—It is officially announced that on Whit-Sunday the extension of the City and South London Railway, from Stockwell to Clapham Common, will be opened, the first train running from either terminus at noon.

Anglo-German Cable.—The German Reichstag on Friday last passed the third reading of a supplementary estimate providing for the expenditure of 2,000,000 marks on the construction of a new cable between Germany and England. The expense of laying this cable from Borkum to Bacton Norfolk) is to be borne equally by the two nations.

Projected Electrical Exhibition in Vienna.—In commemoration of the twentieth anniversary of the foundation of the Austrian Electro-technischer Verein, in 1908 an electrical exhibition on a large scale has been planned to be held in Vienna. Prof. Karl Schlenk is president of the executive.

Visit of the Institution of Electrical Engineers to Paris.—The Institution of Electrical Engineers will hold an extraordinary general meeting in Paris on Thursday, August 16th—*i.e.*, two days before the opening of the International Electrical Congress. Particulars of the preliminary arrangements may now be obtained from the secretary of the Institution.

Personal.—Dr. J. Erskine-Murray has left the employment of Marconi's Wireless Telegraph Co. (Ltd.).——Major Pringle, R.E., has been appointed Inspector of Railways under the Board of Trade, succeeding the late Col. Sir F. A. Marindin.——The Senate of the Cambridge University have agreed to confer honorary degrees of the University on Prof. H. Poincaré, Prof. S. P. Langley, and the Earl of Rosse, F.R.S.

Wireless Telegraphy in the Navy.—Experiments on wireless telegraphy were carried out last week between the battleships "Jupiter" and "Hannibal." The "Hannibal," which was under way, clearly read the "Jupiter's" messages at 20 miles, while the "Jupiter," which was stationary, distinctly read the "Hannibal's" messages at 32 miles distance in the morning, and at 25 miles in the afternoon.

The Royal Society.—Among the papers down for reading yesterday, were:—"On the Estimation of the Luminosity of Coloured Surfaces used for Colour Discs," by Sir W. de W. Abney, F.R.S.; "The Sensitiveness of Silver and some other Metals to Light," by Major-General Waterhouse, and "The Crystalline Structure of Metals," second paper, by Prof. Ewing, F.R.S., and W. Rosenhain.

Physics at Oxford University.—It is understood that an appointment will shortly be made to the Wykham Professorship of Physics to be endowed by New College. A portion of the Radcliffe Library will be temporarily utilised as a laboratory for the teaching of electricity. Merton College has contributed a sum of £700 towards the cost of fitting up, and £500 towards maintaining for two years the new electrical laboratory.

Interesting Austrian Electric Railway.—According to the *Engineer*, a funicular railway has been proposed for Trieste, to connect the town, which is in a hollow at the foot of the Karst, with Opcina. At present, to reach Opcina, which is distant from Trieste only 1·28 miles as the crow flies, it is necessary to travel first to Vienna, the line for which makes a long detour, and the journey to Opcina takes from one to one and a half hours. The line will be narrow-gauge, and 3·1 miles long. The steepest portion of the line, the gradient of which is 1 in 4, will be laid down on the rack-and-pinion system. Six stations are to be provided for the present, and the line will be worked on the Abt system by electric power.

The Capacity of Accumulators.—In a recent number of *L'Eclairage Electrique*, M. L. Jumau describes some investigations which he has carried out on the relation between capacity and strength of acid. The experiments were carried out on cells of the Faure type. He found that the capacity increases at first, and then decreases as the strength of the acid is increased, but the concentration which gives a maximum rises with the rate of discharge. The same is true of the positive and negative plates separately; the maxima, however, do not occur at the same values for the concentration, the capacity of the negatives falling off with a strong acid. The greatest capacity would be found in a cell in which the plates were separated, and having strong acid round the positives, and dilute acid round the negatives. This being impossible in practice, the strength of acid should depend on

Digitized by Google

the rate of working, and the area of the negative plates should be greater.

Electrical Developments in South America. — A correspondent, writing from Rio de Janeiro, sends us some interesting particulars of the electrical installation of the city of San Paulo, South America. The power is taken from a waterfall, situated about 22 miles from the city, giving a fall of 71·5 ft., and capable of developing 25,000 H.P. Double turbines are used, each of 48in. diameter, and with a capacity of 3,000 H.P., and these are coupled to three dynamos situated at the ends of three totally independent lines running to the city. The price to be charged for each 16 c.p. lamp is at the rate of 48 reis per hour, this rate being about one-half that previously charged for 10 c.p. gas-burners. The city of St. Paulo has about 150,000 inhabitants, and possesses a large and complete tramway system worked by mechanical power. Coal is imported from England. The installation is the work of the San Paulo Railway Light and Power Co., formed some little time ago with a capital of $5,000,000.

Wireless Telegraph Experiments in Germany.—According to the *Frankfürter Zeitung*, successful experiments have recently been made at Bremerhaven with the Schäfer system of wireless telegraphy. An apparatus with a wire 205ft. high has been put up for the North German Lloyd at Kaiserhafen, to effect communication between Bremerhaven, the Rothesand lighthouse, Borkum, and the fireship Borkum-Riff. It is hoped also to signal successfully between Heligoland and Bremen, a distance of nearly 100 miles. The large Lloyd steamers, adds our contemporary, are gradually all to be equipped with Schäfer apparatus, and the steamer "Seeadler" has been fitted up as an instruction ship for the men.—The Berlin correspondent of the *Daily Chronicle* states that the German lightship on the Borkum reef, at the mouth of the river Ems, has been provided with a set of Marconi apparatus, by means of which messages will be exchanged between ships at sea and the land telegraph station on Borkum island. A charge of 10d. is to be made in addition to the ordinary telegraph charges.

Paris Exhibition Literature.—M. E. Hospitalier, editor of *l'Industrie Electrique*, and M. J. A. Montpellier, editor of *l'Electricien*, are, with the collaboration of no less than 33 well-known engineers and writers on electrotechnical subjects, publishing in 12 to 15 numbers a complete account of "l'Electricité à l'Exposition de 1900." The delay in the completion of the exhibition has resulted in only one number having appeared up to the present, but if the remainder attain the same standard of excellence and command of detail as this one, the publication will not be one of the least valuable products of the exhibition. No. 1 is an account of the "Organisation et Service Généraux de l'Exposition," and gives a full account of the arrangements made and regulations for the light and power distribution, transportation, and telegraphic and telephonic service. The statistics and reprints of regulations are brightened with plans and drawings, and the compilation affords an admirable book of reference. Technical details, such as descriptions of the machinery and plant, are reserved for future numbers. The work is being published by the firm of Vve. C. Dunod and the subscription price of the whole is to be 40fr.

The Chicago Electric Traction Co.—The *Railway and Engineering Review*, of Chicago, states that this company has decided, after careful consideration, on changing the system of operation on its lines from the battery to the overhead trolley. The length of line originally under the control of this company amounted to 21 miles of single track; and this during the past year has been increased by six miles. On account of the level nature of the track throughout its whole length, the conditions were exceptionally favourable for the operation of the battery system, and the withdrawal after a three years' trial can be only regarded in the nature of a reverse. The real reason for this change-over is not that the battery system has been found mechanically ineffectual and unsatisfactory, but mainly because careful estimation reveals the fact that even under the most favourable conditions the cost of operation and maintenance is 50 per cent. above that of the trolley system. In addition, the battery system is said to be unsuited for the operation of branch lines such as are at present contemplated on the Chicago system, because all the advantages of a centrally located power station for the recharging of batteries are then unavailable.

An Italian Electric Furnace.—The Stassano electric furnace, which the *Electrical World and Engineer* of New York states has been tested in an experimental plant of 100 H.P. near Rome, is claimed to reduce the cost of producing iron and steel about one-third. The apparatus resembles in appearance a blast furnace of very small size, the heat being supplied by an electric arc between carbons entering opposite openings at the bottom of the furnace and adjusted by hand. Carbonates and oxides are the ores usually treated. The former are first roasted, and it is necessary to powder all the ores and mix them with such proportion of carbon, lime or silica as analysis may show to be necessary for producing the desired quality of metal, and then to form the powdered mixtures into bricks with 5 or 10 per cent. of pitch under hydraulic pressure. The dried bricks are fed into the heated furnace, the treatment then lasting a little more than half-an-hour in a test producing a small ingot. The process is aided by the combustion of the carbon of the mixture, and the electric energy required for each ton of metal is estimated at 3,000 H.P. hours. Further experiments are to be made with three furnaces of about 500 H.P. each, capable of yielding about 4,000 tons of metal annually.

An Electric Lightship.—According to the *Electrical Review* of New York, one of the largest steam-propelled and electric lighted lightships ever built is to be used off Cape Hatteras, for the purpose of lessening the dangers of navigation off that point. For the protection of shipping there is already a lighthouse about 1¼ miles from the extreme point of the cape, whose focal plane is 190ft. above the level of the sea. A few miles from the shore are the dreaded Diamond shoals, on which vain attempts have been made to erect a lighthouse. The lightship, which has been designed to meet the exceptional difficulties, is to be 112ft. long, 28ft. 6in. beam, and a depth of 14ft. 10in. The dynamos and engines for the electric light plant will be located on the main deck, and within the engine and boiler casing. There will be two hollow steel masts, through which the wiring for the masthead flashlights is to run. These lights, three in number on each mast, are to be adapted for electricity or for oil-lamps. The electric plant will be driven by two non-condensing, double cylinder engines, running with 80lb. steam pressure. The vessel will be lighted by 80 16 c.p. 100-volt lamps. The masthead cluster, 59ft. above the water line, will consist of 6 100 c.p. 100-volt lamps, to be controlled by an automatic flashing device. In addition to a steam-whistle, the lightship will be provided with a steam siren, for use in thick and foggy weather.

Obituary.—We regret to announce the death on Saturday last, at the age of 56 years, of Mr. William Johnson, until recently the Corporation electrical engineer and manager of the Sheffield electric supply works. Mr. Johnson had been in ill-health for some time past, but his death will, nevertheless, come as a surprise and be received with regret by all his numerous friends. Under Mr. Johnson's control the system of electric supply at Sheffield was brought to a high state of perfection in the face of innumerable difficulties, firstly under the Sheffield Electric Light and Power Co., as well as after the transference of the undertaking to the Corporation. Mr. Johnson was also prominently associated with the development of the telephone in this country, having been the inventor of a well-known transmitter called after his name, besides being largely connected with the establishment of the telephone system in Sheffield.

We have also to record the death, at his residence, Cottenham Park, on May 7, of Mr. Frederic Wyles, assistant electrical engineer to the London and South Western Railway, Waterloo Station, London, at the early age of 39. Mr. Wyles was an active member of the Institution of Electrical Engineers, and took a deep interest in all matters appertaining to his profession. The London and South Western Railway Co. has sustained a great loss by the death of a most capable officer, and the utmost sympathy is extended to his widow and children. At the interment at Wimbledon New Cemetery nearly 200 railway men of all grades assembled.

Patent Procedure.—The committee to inquire into the advisability of some reforms in patent procedure has been constituted as follows by the Board of Trade: Sir Edward Fry (chairman); Sir Richard Webster, Bart., G.C.M.G. (Master of the Rolls); Sir Edward Carson, Q.C., M.P. (Solicitor-General); Sir William H. Houldsworth, Bart., M.P.; Mr. F. J. S. Hopwood, C.B., C.M.G.; Mr. S. E. Spring-Rice, C.B.; Mr. J. Fletcher Moulton, Q.C., M.P.; Col. Thomas W. Harding; Mr. Edward Carpmael; and Mr. Herbert Hughes. Mr. Arthur Paget, barrister-at-law, has been appointed secretary to the committee. The reference to the committee is:—

While Her Majesty's Government do not think it desirable and do not propose to establish any general system of examination as to the novelty of inventions in respect of which applications for letters patent are made, and do not require any inquiry into any such system of examination, the committee hereinbefore appointed is to inquire into the working of the Patents Acts with reference to the following questions:—

(1.) Whether any, and, if so, what, additional powers should be given to the Patent Office to (*a*) control, (*b*) impose conditions on, or (*c*) otherwise limit the issue of letters patent in respect of inventions which are obviously old, or which the information recorded in the office shows to have been previously protected by letters patent in this country;

(2.) Whether any, and, if so, what, amendments are necessary in the provisions of Section 22 of the Patents, &c., Act, 1883; and

(3.) Whether the period of seven months' priority allowed by Section 103 of that Act to applicants for letters patent under the International Convention may properly be extended, and, if so, on what conditions.

Buxton Electricity Works.—The electricity works of the Buxton Urban District Council have recently been opened. The provisional order was obtained in 1894, but no steps were taken to give effect to this order until 1898, when Prof. A. B. W. Kennedy was invited to report on the system of electric supply best suited to the conditions and requirements of the district. Prof. Kennedy advised a three-wire low-pressure system of supply, the voltage being about 230 volts. A handsome brick building was erected on a site near the gas works, at a cost of £5,000, while the expenditure to date on machinery, feeders, mains, lamps, posts, &c., amounted to £14,000. The station equipment consists of three Hornsby water-tube boilers, capable of evaporating 4,500lb. of water per hour; four Bellis high-speed engines of a total of 320 H.P. and direct-coupled to six four-pole Mather and Platt continuous-current dynamos, having a total capacity of 198 kw. For the day load a battery of accumulators has been installed, and contains 260 cells of Tudor type, with a capacity of 250 ampere-hours and a maximum discharge rate of 100 amperes. The feeding and distributing mains were supplied by the Callender Cable and Construction Co. and consist of concentric, lead-covered, and armoured cables for the feeders, and triple-concentric cable for the distributors. Mr. Kenneth Watson superintended the erection of the installation on behalf of Prof. Kennedy, and Mr. Edward Calvert is the chief electrical engineer appointed by the District Council.

Municipal Electrical Association.—The following is the programme of the Municipal Electrical Association meeting at Huddersfield from June 20 to June 23 inclusive. First day: Meeting at 10 a.m. at Technical College to hear Mr. A. B. Mountain's Presidential Address; two Papers on "Means for Stimulating the Demand for Electrical Energy," by Ald. W. Potter, of Taunton, and H. C. Bishop, of Wigan; and two Papers on "Electricity Works for Small Towns," by C. S. Vesey-Brown, of Lincoln, and G. M. Harris, of Bray. In the afternoon the Bradford Corporation Electricity and Tramway works will be visited. In the evening a dinner will be given in the Town Hall by Mr. Joseph Hopkinson. Second day: Meeting at 10 a.m. at Technical College; two Papers on "Electric Motors," by T. P. Wilmshurst, of Derby, and C. A. L. Prussmann, of Doncaster; a Paper on "Combined Management of Tramways and Lighting Departments," by R C. Quin, of Blackpool; and a Paper on "Methods of Reducing Light Load Losses," by H. L. P. Boot, of Tunbridge Wells. In the afternoon the mayor gives a garden party; in the evening the Association Dinner at the Town Hall. Third day: Meeting at 10 a.m. at the Albert Hall, Leeds; two Papers on "The Distribution of Electricity in Scattered Areas," by L. Andrews, of Hastings, and G. Wilkinson, of Harrogate; a Paper on "Maintaining Certain Portion of Electrical Distribution Systems at Earth Potential," by C. H. Wordingham, of Manchester; a Paper on "Impressions of Present American Tramway Practice," by A. E. Le Rossignol, of Newcastle-on-Tyne; and a Paper on "Protection of Telegraph and Telephone Lines," by R. C. Quin, of Blackpool. In the afternoon a visit will be paid to the Leeds Electricity Works and Tramway Power Station. Fourth day: The business meeting of the Association. We are asked to state that the Council of the Association cordially invite all who may be interested to attend the meetings; also that copies of the Papers and any further information as to local arrangements may be obtained from the president, Mr. A. B. Mountain, Corporation Electric Supply Works, St. Andrew's-road, Huddersfield.

Physics Congress at the Paris Exhibition. — The International Congress, organised by the French Physical Society, will be held in Paris, August 6th to 12th. The programme has been divided into three parts: (1) Various communications and lectures on some new questions; (2) Visits to the exhibition, laboratories and works; and (3) Papers and discussions on subjects decided upon beforehand. Over seventy papers have already been promised on various subjects by different authors. Among the authors and subjects are the following:—

M. M. ABRAHAM: Determination of *v*. ARRHENIUS: Electrolysis and Ionisation. D'ARSONVAL: Currents of High Frequency in the Organism. BECQUEREL: Uranium Rays. BICHAT and SWYNGEDAUW: Actino-electric Phenomena. BLONDEL: Recording Variable Electric Currents, Oscillographs and Rheographs. BLONDLOT and GUTTON: Speed of Electric Waves. BOUTY: Gaseous Dielectrics. BOYS: The Constant of Gravitation. BRANLY: Variation in the Resistance of Tubes of Filings. BROCA: Transmission of Energy in the Organism. CHRISTIANSEN: Contact Electricity. CORNU: Speed of Light. CURIE (M. et Mdme.): New Radio-active Substances and the Becquerel Rays which they emit. DRUDE: Optical Properties of Metals. DU BOIS: Magnetic Properties of Bodies. EÖTVÖS: Study of Electric and Magnetic Equipotential Surfaces. EXNER: Atmospheric Electricity. PRINCE GALITZINE: The Critical Index. GOUY: Standard of Electromotive Force. GUILLEAUME: International Decisions Concerning Units and Nomenclature; Various Propositions. GRIFFITHS: The Unit of Heat. HURMUZESCU: Electromotive Force of Magnetisation. LORD KELVIN: Conditions of the Formation of Ether Waves by the Displacement of Ponderable Matter; Non-Oscillatory Character of these Waves for Speeds of Displacement less than that of Light. VON LANG: The Electric Arc. LEDUC: Electro-Chemical Equivalent of Silver. LIPPMANN: The Absolute Scale of Temperatures LORENTZ: Magneto-Optics. NAGAOKA: Magneto-Striction. PAULSEN: The Polar Aurora. PELLAT: National Laboratories. H. POINCARÉ: Relations between Experimental Physics and Physical Mathematics. L. POINCARÉ: Theories of the Voltaic Pile. POTIÉR: Polyphase Currents. POYNTING: Theory of the Propagation of Electricity. RIGHI: Hertzian Waves. RUBENS: On Wave Lengths. J. J. THOMSON: Electric Discharges in Gases. VILLARD: Cathode Rays. VILLARI: The Ionisation of Gases. VIOLLE: Speed of Sound. WARBURG: Magnetic Hysteresis. W. WIEN: Temperature and Entropy of Radiation. WITZ: Recent Progress in the Theory of Heat Engines.

Proofs of the majority of these Papers, which will be in French, may be obtained beforehand by those who are going to take part in the Congress. Further particulars may be ascertained from M. Lucien Poincaré, Secretary of the Commission of Organisation, 105 bis, Boulevard Raspail, Paris.

MEETINGS OF SCIENTIFIC AND ENGINEERING SOCIETIES, &c.

(To-day) FRIDAY, June 1st.

ROYAL INSTITUTION.

9 p.m. Evening Discourse by Sir Henry Roscoe, F.R.S., subject "Bunsen."

THURSDAY, June 7th.

RÖNTGEN SOCIETY.

8 p.m. Ordinary General Meeting in the Electrical Department of St. Bartholomew's Hospital, Smithfield, when: (1) Dr. Lewis Jones will show an influence machine of American design; (2) Mr. James Wimshurst will give a short statement of his work in the design and perfecting of the several forms of his influence machine; (3) Dr. Rémy, of Paris, will show a new localising apparatus.

FRIDAY, June 8th.

PHYSICAL SOCIETY.

5 p.m. Meeting in the Rooms of the Chemical Society, when the following Papers will be read: (1) "On the Magnetic Properties of Iron and Aluminium Alloys, Part II.", by Dr. S. W. Richardson; (2) "Note on the Crystallisation Produced in Solid Metal by Pressure," by W. Campbell; (3) "On the Viscosity of Mixtures of Liquids and of Solutions," by Dr. C. H. Lees.

ROYAL INSTITUTION.

9 p.m. Evening Discourse on "The Effect of Physical Agents on Bacterial Life," by Allan Macfadyen.

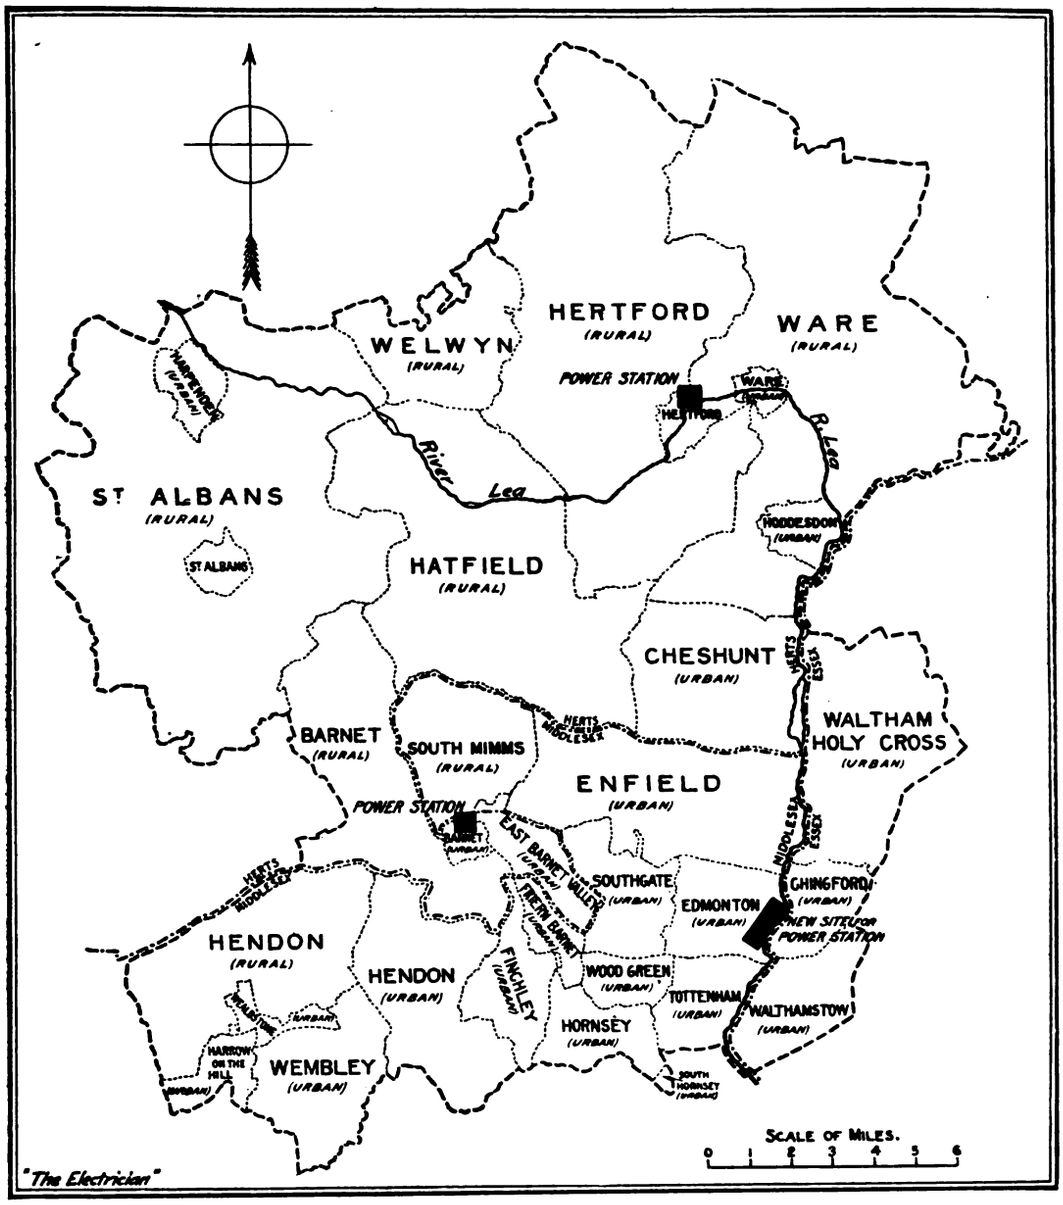
PROJECTED ELECTRICAL POWER SCHEMES.

(*Continued from page 81.*)

5. North Metropolitan Electric Power Scheme.—For the moment we turn from the series of power schemes which is being considered by the Parliamentary Committee, presided over by Sir James Kitson, to deal with a similar scheme of equal importance, which, during the past week, has come before another Committee of the House of Commons, presided over by Mr. H. A. Brown. This is the scheme of the North Metropolitan Electric Power Supply Co., the promoters of which are Messrs. E. Garcke, W. L. Madgen, J. S. Raworth, and R. P. Sellon—the same, in fact, as for the County of Durham scheme, described in our issue of May 4, p. 58. The accompanying map shows the area it is proposed to supply with electric power under this scheme. The capital, to obtain which powers are sought, is £270,000 in £10 shares, with borrowing powers up to £90,000 in debenture stock. Our "Parliamentary Intelligence" columns this week give particulars of the scheme and of the examination of witnesses by the Committee. Meanwhile Sir J. Kitson's hard-working Committee is still considering the Lancashire scheme, of which we have given our readers a full description.

(To be continued.)



MAP OF THE NORTH METROPOLITAN ELECTRIC POWER SUPPLY CO.'S PROPOSED AREA OF ELECTRICITY SUPPLY.

PUBLIC ARC LIGHTING IN ST. MARTIN'S PARISH.

The lighting of the streets of London has for long been a subject for complaint, and if the ratio of the number of electrically-lighted to gas-lighted streets were calculated for all our larger towns, it would probably be found that the figure obtained for London was among the smallest. This is due no doubt to the fact that the electric lighting of the main parts of London is in the hands of companies, while in other large cities the corporation owns the electric light works; it is, therefore, a matter for congratulation that another of the metropolitan local authorities has been wise enough to erect arc lamp-posts, and to enter into an agreement with a supply company for the lighting of the principal streets in the parish. In all, 97 10-ampere (1,000 nominal c.p.) open arc lamps have been erected in St. Martin-in-the-Fields, and they are distributed as follows:—

Haymarket, 5 lamps; Panton-street and Whitcomb-street, 5; Leicester-square, 4; Pall Mall East, 2; Cockspur-street, 2; Trafalgar-square, 7; Charing Cross and Whitehall, 5; Horse Guards-avenue, 2; Whitehall-avenue, 2; Whitehall-place, 3; Northumberland-avenue, 6; Strand, 14; Agar-street, 1; King William-street, 1; Chandos-street, 2; Adelaide-street, 1; Duncannon-street, 1; St. Martin's-place, 2; Charing Cross-road, 5; Green-street, 1; St. Martin's-lane, 6; Garrick-street, 2; Cranbourne-street, 2; Upper St. Martin's-lane, 1; Long-acre, 9; Endell-street 1; Villiers-street 5.

Digitized by Google

Before deciding to let the contract for street lighting to the Charing Cross and Strand Electricity Supply Corporation, the Vestry instructed their surveyor, Mr. George Green, to report on the advisability of the Vestry erecting its own generating station in combination with a refuse destructor. Mr. Green wisely reported against the latter alternative, and recommended that tenders should be invited from the three supply companies who have mains laid in the parish, with the result that the contract was awarded to the company mentioned above. The

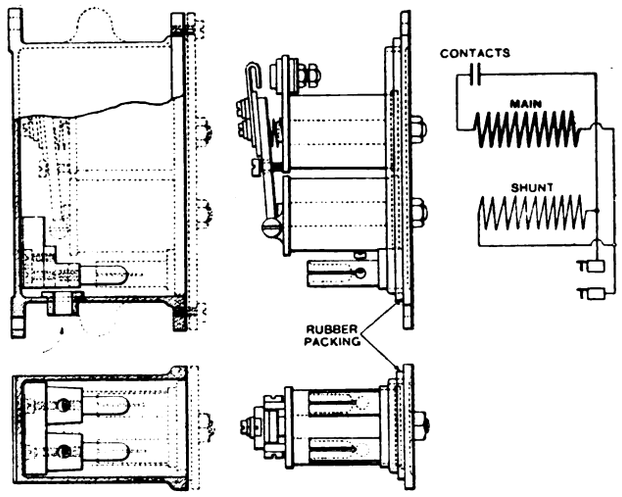


FIG. 3.—AUTOMATIC CUT-OUT. (One-fourth size.)

new street lighting was "inaugurated" on Wednesday last week, in honour of the Queen's birthday.

The lamps are connected in circuits of 20 in series, and are supplied from the Maiden-lane station of the Charing Cross Co. The circuits are connected to a switchboard independent of the main switchboard, and the current at 1,000 volts is

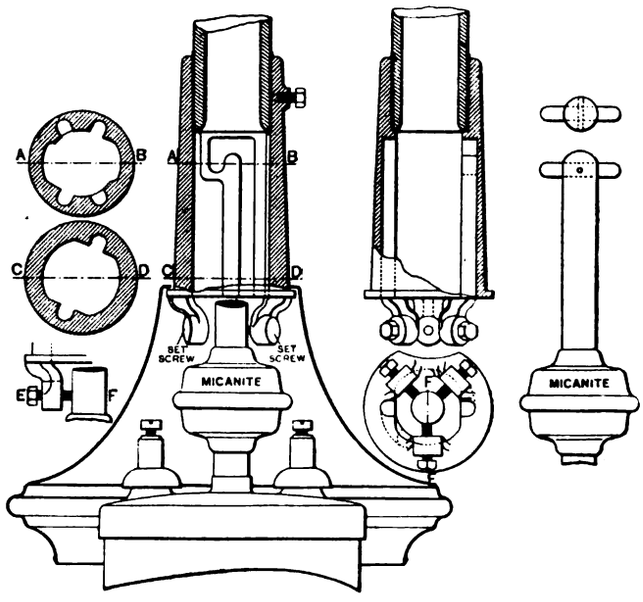

FIG. 4.—DETAILS OF ATTACHMENT FOR CENTRE LAMP AND WEATHER-PROOF HOOD. (One-fifth size.)

supplied by continuous-current converters, whose low pressure side is connected to the low-pressure 'bus bars. Each arc circuit is connected through an ammeter, a double-pole switch, Bates' fuses on each pole, and a series regulating resistance; and a voltmeter is connected across the two poles. As the low-pressure 'bus bars of the Maiden-lane station are supplied chiefly from 1,000-volt continuous-current generators at the company's station in Lambeth through step-down continuous-current converters in the former station, it is seen that the current for the arc circuits undergoes two transformations, although it is supplied to the circuits at practically the pressure at which it is generated. The reason for this is that at present the trunk mains between the two stations are too valuable to allow the arc lighting circuits to be connected to them directly. Probably when the new switchboard at Maiden-lane (to replace the one destroyed in the recent fire) has been completed, an alteration in the connections of the arc circuits will be made.

The cables are all 19/18 S.W.G. single vulcanised bitumen cables (made by Callender's Co.), and they are laid in ordinary Doulton ducts, with three 3in. ways, jointed on cement cradles in the usual manner. Near the station, which is at one corner of the area in question, the go and return cable run together, but in some parts a considerable amount of cable is saved by running them separately. In the case of alternating and rectified current arcs the go and return main cannot be separated in this way on account of induction effects on neighbouring telegraph and telephone circuits, and this

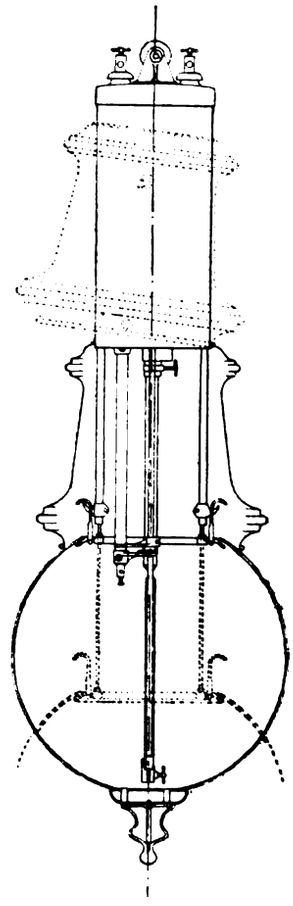

FIG. 5.—METHOD OF LOWERING GLOBE FOR TRIMMING.

advantage of the series-continuous-current method is often overlooked when comparing different systems. Another interesting fact is that no attempt has been made to crowd in more than 20 arcs on the 1,000-volt circuit, although some engineers assert that they have been successful in running nine lamps between 440 and even 400-volt mains. The lamps with their regulating coils take 45 volts each; no steadying resistances other than the series regulating coils themselves are placed between lamps, but all is included in the regulating resistance at the station. With one exception there are no joints in the cables, and the cable is in each case run right up to the switchboard in the lamp pillar and out again. The exception is merely a straight-through joint in the longest length of cable, there being no T joints at all and no surface boxes other than an occasional draw-box to help sharp bends to the lamp posts.

Two patterns of lamp post are employed, the centre type, shown in Fig. 1, placed on refuges in the roadway, and the swan-neck type of Fig. 2. The lamp in the former is reached

Digitized by Google

by means of climbing irons, while in the latter case the lamp is lowered for trimming. The posts are by Messrs. Singer and Sons. They are painted a bright cherry red, which is somewhat obtrusive at present, but will no doubt soon get toned down by the effects of weather. The illustrations enable a comparison to be made between the appearance of the electric lamps and the now disused gas lamps.

In the base of each post is a switchboard on which an isolating switch and an automatic cut-out are mounted, and next to it the substitutional resistance. The switch is of the pattern with laminated C-shaped springs, in the jaws of which the rotating contact bar fits. It has, of course, only two positions, one in which the lamp is connected between the two cable ends, and the other in which both terminals of the lamp are isolated and the substitutional resistance is connected in its place. The shape of the key for turning the switch, and of the key-hole cut in the cast-iron cover of the switch, are such that the key cannot be removed when the switch contacts are in an intermediate position. The automatic cut-out is constructed on the usual principle. It is simple and compact—taking up, in fact, less room than the switch—and has the advantage that the whole of the mechanism is attached to the cover, and can be withdrawn easily for examination, the contact being made through the spring thimbles seen in Fig. 3. The two terminals TT are connected in series with the substitutional resistance (not shown in the diagram) and shunted across the lamp. Thus normally the circuit of the upper or "main" coil of the device is open, while the shunt coil is permanently connected across the lamp terminals. When a lamp "hangs up," or if its carbons are burnt down, the current through the shunt coil increases and the armature is attracted against the magnets, closing the two contacts. As soon as this happens, both the substitutional resistance and the "main" coil of the cut-out are in circuit in place of the lamp, and the latter coil being energised draws up the armature tighter and ensures good contact. On the lamp feeding again, as soon as the carbons meet, both coils of the cut-out are shunted by them, and the armature is again released, there being practically no sparking as the coils are short-circuited. The cut-out comes into action when the arc has lengthened sufficiently to require 60 volts. Connection is made between this switchboard and the lamp by means of lead-covered vulcanised rubber cables.

The lamps as well as the auxiliary apparatus already alluded to are made by Messrs. Oliver and Co., of Woolwich, a comparatively new firm of arc lamp manufacturers not yet very well known among central station engineers, as it has chiefly b en occupied in supplying some of the large railway companies. Another sample of its street lighting work may, however, be seen at Leyton. An examination of the lamp shows that the manufacturers' chief aim has been to attain simplicity in construction, and this combined with workmanlike finish and a strict interchangeability of parts is evidently the key to the good working of the lamps, for we understand that the Charing Cross Co. are well satisfied with the way in which they burn. The well known clutch principle (which, we believe, has been tried and again abandoned by some makers) is adopted, and the design of the lamps, which shows evidences of having been most carefully thought out in every detail, is such that any part may be taken out by the removal of two screws, and replaced, without prejudicing the adjustment of any other part. The framework is of a substantial character, to withstand rough usage. To the crown or top plate of the lamp are attached exceptionally strong main and shunt regulating coils, in which annealed iron cores work in the usual manner,

FIG. 1.—LAMP OPPOSITE THE NATIONAL PORTRAIT GALLERY.

FIG. 2.—SIDE-LAMP IN KING WILLIAM STREET, STRAND.

Digitized by Google

being pivoted below to a cradle or rocking frame, this directly controlling the working of the clutches. Adjustment for the current and voltage is made by the addition of a weight to either end of the cradle. A large air dash-pot (1½in. diameter) is attached to the latter, the plunger being rigidly held to the base-plate or bottom frame of the lamp, so that the cylinder which works over the plunger is inverted, preventing the accumulation of dirt in it and consequent sticking. By means of attaching the positive rod, on which the clutch works, by a flexible copper cord over a pulley to the negative (not directly, of course, but with the intermission of a mica-insulated washer), the lamp is made focussing. The current is carried to the positive and negative rods inside the case, thus doing away with loose connections in the globe, and the lamp is insulated from the case by little piles of mica, this insulation being used wherever possible.

Among the details deserving notice are the bayonet type of attachment used for holding the centre lamps rigidly, the design of which is evident from Fig. 4, and the method of lowering the globe for trimming, shown in Fig. 5. Another interesting feature is that the top globe ring is inside instead of outside the globe, so that the ring itself and not the wires of the netting bear the weight of the globe. This ring is all in one piece, and at first sight, until two slots at opposite sides of the ring are observed, it is not evident how it has been got within the globe. The side lamps are lowered by means of a winch worked by a key passing through the side of the base of the post. Before being able to lower the lamp it is necessary to open the post in order to release the pawl of the ratchet. The steel wire from the lamp to the winch passes over a pulley through the centre of the weather hood, and then over a second one and through the centre of the post. Contact is made, when the lamp comes up into position, through concentric rings and copper brushes.

In preparing this article much information has been given us by Mr. Oliver, of Messrs. Oliver and Co., and by Mr. Percy Mossop, distributing engineer of the Charing Cross and Strand Co., who has been responsible, under Mr. Patchell, the engineer-in-chief, for putting down the arc lighting system. We wish to tender our thanks to these gentlemen, who have afforded us every facility to inspect the lamps and the details of the system.

THE CENTRAL LONDON RAILWAY.

Introductory.—The Central London Railway is a deep level twin tunnel electric railway running between a point below the roadway in front of the Bank of England and Shepherd's Bush, a distance of 5¾ miles. Besides the two terminal stations, there are 11 intermediate passenger stations. The power house, with the sheds, sidings, yard space, &c., is situated a short distance beyond the Shepherd's Bush terminus. The railway is designed to provide a 2½-minute service of trains. It is probable, however, that the service will ultimately be increased to 2 minutes.

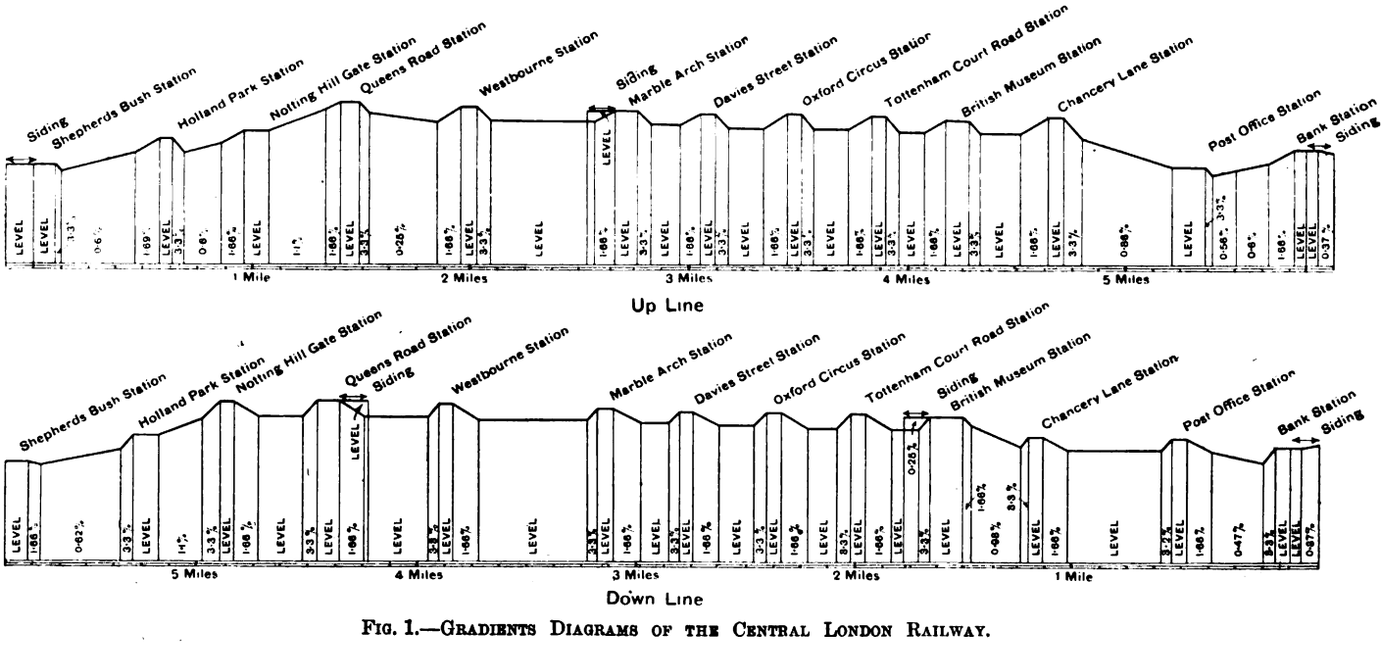

FIG. 1.—GRADIENTS DIAGRAMS OF THE CENTRAL LONDON RAILWAY.

The electrical equipment of this railway is now practically completed, and experimental trains are running frequently with a view to testing the general construction, and also to get the staff practised in the somewhat novel arrangements of the train service. Considerable work, however, remains to be done, principally at the passenger stations, so that some weeks must yet elapse before the line can be opened to the public. The electrical work, however, being completed, the present is an opportune moment for commencing a technical description of this equipment, with some general account of the other features of the railway; as this description must necessarily occupy the space of several articles, we hope to have the series completed before the inauguration of the line takes place.

Before proceeding to consider the engineering features of the line, we will briefly survey the chief events in its development. In 1890 the first Central London Railway Bill was promoted. By this bill it was proposed to construct a deep-level twin-railway on the Greathead system, at a depth of 40ft. or 50ft. below the surface, between Queen's-road, Bayswater, and the King William-street terminus of what was then known as the City and Southwark subway, now called the City and South London Railway. Owing to opposition, however, this bill was rejected. In 1891 a new bill was promoted, and passed, for a line running from Shepherd's Bush to the Bank of England. Trial borings were sunk in November, 1891, in the neighbourhood of Uxbridge-road, these revealing satisfactory conditions as regards excavations. In the following year it was proposed to extend the line to Liverpool-street. This proposal, however, has not yet been carried out. In 1894, powers were obtained to defer the completion of the undertaking until 1900.

The Central London Railway Co. was incorporated on

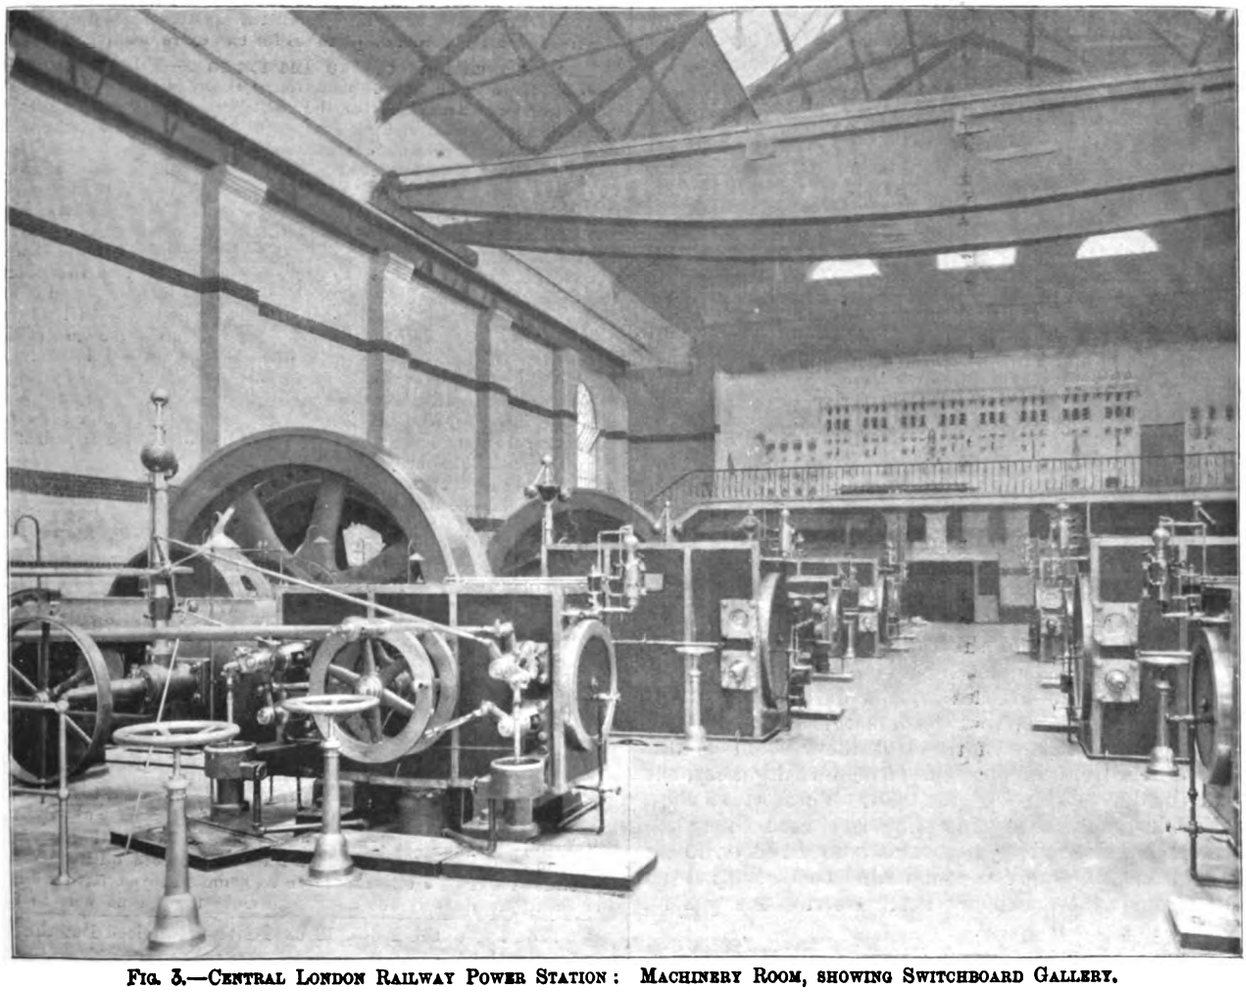

FIG. 3.—CENTRAL LONDON RAILWAY POWER STATION: MACHINERY ROOM, SHOWING SWITCHBOARD GALLERY.

Digitized by Google

Aug. 5, 1891, with an authorised share capital of £2,700,000 and £900,000 borrowing powers. In 1894 the capital was increased to £2,850,000, with further borrowing powers of £50,000. It appears that up to the present time the amount of capital received is £2,411,092.

A contract was entered into in June, 1895, between the Central London Railway Co. and the Electric Traction Co. for the acquisition of lands and the construction and equipment of the entire railway for the sum of £3,114,000, payable partly as to £672,000 in 4 per cent. debenture stock and the remainder in cash. The engineers appointed by the company were Sir John Fowler, Sir Benjamin Baker, and Mr. Greathead; but since the decease of Mr. Greathead, Mr. Basil Mott has acted as one of the engineers. In July, 1895, the engineers were instructed to proceed immediately with the construction of the work.

Contracts for the electrical equipment of the power station, sub-stations, track, rolling stock, passenger stations, &c., were placed with the British Thomson-Houston Co. Mr. H. F. Parshall was appointed consulting engineer for the electrical equipment, and under his direction the entire work of constructing the power house and equipping the rolling stock, line, &c., has been ably carried out.

The system adopted for this railway is one which has never before been tried in this country, and, indeed, never on any very extensive scale in any part of the world. It was decided to equip the power station on the three-phase 5,000 volt system and to transmit three-phase currents at the generating

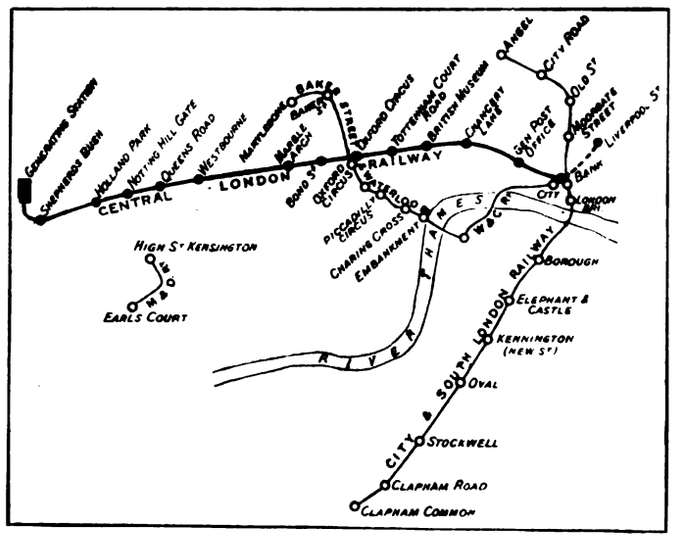

FIG. 4.—SKETCH MAP OF THE CENTRAL LONDON RAILWAY.
——— Central London Railway. ——— Other Electric Railways.

pressure to sub-stations along the line. At these sub-stations the power would be transformed down to the working pressure of 550 volts and from polyphase to continuous current. The continuous current is to be fed at numerous points along the line from distributing cables to a third-rail working conductor placed between the track rails. The return current is carried through the metallic conductor afforded by the track rails. There are at present three sub-stations, viz., at the passenger stations at Notting Hill Gate, Marble Arch and the Post Office.

As already stated, the power station is now quite completed, while many parts of the railway remain as yet unfinished. It will be convenient for this reason, therefore, to commence our series of articles with a description of the power station. We present our readers this week with two recent views of the interior of the machinery room at this station, one taken from the spacious switchboard gallery, the other from the opposite end of the hall. These views show the six 850 kw. polyphase generating sets, each consisting of a G.E. three-phase railway generator built direct on to the shaft of a horizontal cross-compound Allis condensing steam engine. In our next article we shall describe the general equipment of this power house.

(To be continued.)

REPORT OF THE COUNCIL OF THE INSTITUTION OF ELECTRICAL ENGINEERS.

The following is an abstract of the report of the Council of the Institution of Electrical Engineers for the session which has just closed:

Local Sections.—Active local sections are now in operation in Dublin, Glasgow, the Manchester district, and Newcastle, the Manchester section having taken the place of the late Northern Society of Electrical Engineers now incorporated in this Institution. A local section has also been created in Cape Town. General rules and regulations for the management of local sections at home and abroad have been drawn up, and the organisation of the sections has already assumed a definite form.

Elections and Transfers.—The Council has the pleasure to report that during the twelvemonth ending May 24, 1900, acting in accordance with Article 17 of the Articles of Association, it has elected Mr. Joseph Wilson Swan, F.R.S., the last past-president of the Institution, an honorary member.

Notwithstanding the increased severity of the rules relating to the qualifications for membership, and the strictness with which those rules are enforced, the total of the additions to the register by election at ordinary general meetings during the same period has been 401. This number is much above the average, and is made up as follows:—25 members, 88 associate members, 3 foreign members, 152 associates, and 133 students. Adding to these the honorary members and the new members transferred from the Northern Society of Electrical Engineers at the time of incorporation, the total is 471, comprising one honorary member, 53 members, 113 associate members, three foreign members, 168 associates, and 133 students.* Six associate members, one foreign member, and 12 associates have been transferred to the class of members, whilst 85 associates have been transferred to the class of associate members, and 33 students to that of associates.

Deaths and Resignations.—The Institution has to mourn the loss by death of one past-president, Prof. David E. Hughes; nine members, Mark Bevan T. Buckney, J. D. Doyle, P. B. Elwell, L. Epstein, Frank King, Joseph B. Morgan, Benjamin Smith, and Frederic Wyles; and eight associates, J. Chapman, H. J. Clipperton, H. T. Constable, M. Cooper, W. B. Edgar, J. J. Tough, W. C. Smythe, and L. G. Willmott. Three members, two associate members, one foreign member, 23 associates, and five students have resigned since the date of the last report.

Ordinary General Meetings.—The attendance at the ordinary general meetings has been well maintained. By the kind hospitality of the two societies, the meetings from November to April have been held, as in previous years, in the rooms of the Institution of Civil Engineers, and two of those in May in the rooms of the Society of Arts. The Institution is now further indebted to the Institution of Mechanical Engineers for the privilege of using their new premises for two extra meetings in May.

The Publications of the Institution.—With reference to the *Journal*, the only change of note to be recorded is the alteration in the date of the commencement of the volume, which now runs concurrently with the session. The first number of the current volume, therefore, contained the proceedings of the meetings in November and December, 1899, instead of those in January, 1900, as would have been the case under the old system.

Recognising the great value of *Science Abstracts* to the electrical engineer in placing before him an epitome of most of what is valuable in the current literature of his subject throughout the world, the Council has agreed with the Physical Society for the continuance of the publication under the joint control of the two societies for a further period of at least three years, or of so much longer as may be found mutually agreeable. The scope of the *Abstracts* has now been enlarged, sections relating to steam plant, oil and gas engines, motor cars, and medical electricity having been added, so that the work now appeals to a larger circle of readers than it has done previously, and the growing appreciation in which it is held is indicated by a considerable increase in the proceeds from sales to non-members of the two societies. The number of *Abstracts* published was increased from 1,425 in 1898 to 2,000 in 1899.

The publication of the following papers in the *Journal* as original communications has been ordered:—

In Part 142.—"How Condenser and Choking-Coil Currents Vary with the Shape of the Wave of the Applied E.M.F."	A. Russell, Member.
In Part 144.—"A Two-Phase Rotary Converter and a Note on the Regulation of Rotary Converters"	E. Wilson, Member.
In Part 144.—"The Air-Gap Induction in Continuous-Current Dynamos"	C. C. Hawkins, M.A., Member. R. Wightman, Assoc.
In Part 146.—"Note on Air-Gap and Interpolar Induction."	F. W. Carter M.A., Associate.
In Part 146.—"The Reluctance of the Teeth in a Slotted Armature"	W. B. Hird, Member.
In Part 146.—"On the Absolute Values of Capacity Measurements."	J. Elton Young, Member.

Annual Premiums.—The Council has awarded the following premiums for Papers and communications accepted during the current year. No Paper on a telegraphic or telephonic subject having been read, the Fahie premium is not awarded. Only those that were in type on

* In addition to the above, 19 candidates were elected at the general meeting on May 24.

Digitized by Google

May 10 were considered eligible, Papers accepted for publication after that date being reserved for consideration in awarding the premiums in 1901:—

The Institution Premium (value £25) to Mr. C. E. Grove, member, for his Paper on "The Electrical Equipment of Ships of War."

The "Paris Electrical Exhibition Premium" (value £10), to Mr. S. Evershed, associate member, for his Paper on "A Frictionless Motor Meter."

Two Extra Premiums (value £10 each) respectively to Prof. George Forbes, F.R.S., member, for his Paper "On Distant Electric Power Transmission," and to Mr. H. M. Sayers, associate member, for his Paper on "The Calculation of Distributing Systems of Electric Tractions, under British Conditions."

Premiums for Original Communications published in Journal (value £5 each) to Mr. A. Russell, member, for an "Original Communication" entitled "How Condenser and Choking-Coil Currents Vary with the Shape of the Wave of the Applied E.M.F.," and to Messrs. C. C. Hawkins, member, and R. Wightman, associate, for an "Original Communication," entitled "The Air-Gap Induction in Continuous-Current Dynamos."

The First "Students' Premium" (value £10) to Mr. R. P. Howgrave-Graham, student, for his Paper on "Hertz Waves and Wireless Telegraphy."

The Second "Students' Premium" (value £5) to Mr. C. B. Nixon, student, for his Paper on "Switch Gear for the Generation of the Electric Current."

The Third "Students' Premium" (value £5) to Mr. H. J. Humphreys, student, for his Paper on "Permanent Magnets."

Salomons Scholarship.—The Council has awarded a Salomons Scholarship, value £50 to Mr. R. P. Howgrave-Graham, of the Technical College, Finsbury.

Students' Class.—Twelve meetings of the students' section have been held during the session, at ten of which Papers were read by students, the remaining two having been devoted to discussions on electrical subjects. Visits to the following places were arranged for the students by the secretary during the year, and the Council desires to express its thanks to those who, by opening their works for the purposes of these visits, have contributed much to the usefulness of the section:—Bankside station of the City of London Electric Lighting Co., Davies-street station of the Westminster Electric Supply Corporation, London United Tramways, Waterloo and City Railway, and the works of Messrs. Easton, Anderson and Goolden, the Electric Welding Co., the Incandescent Electric Lamp Co., the India-Rubber, Gutta-Percha and Telegraph Works, the Langdon-Davies Electric Motor Co., and Messrs. Siemens Bros. and Co.

Annual Accounts and Financial Position.—The surplus of income over expenditure at the end of 1899, as shown in the annual statement of accounts, demonstrates that, notwithstanding the contribution in respect of *Science Abstracts* and the increased expenditure on premiums, the financial position of the Institution is thoroughly sound.

Building Fund.—The importance of erecting a permanent home for the Institution is recognised by the Council, and they have, accordingly, taken steps to augment the building fund. They have transferred from the general fund the sum of £1,437. 10s. 9d., and they have also invited members to make special contributions to the fund. In response to this appeal £131. 11s. 6d. was paid during the two months of 1899 which remained after the date of issue of the circular. These sums, with the interest on capital previously invested on this account and other payments, have raised the amount standing to the credit of the fund on Dec. 31, 1899, to £7,044. 5s. 11d., as against £5,277. 0s. 6d. at the end of 1899.

Wilde Benevolent Fund.—During the session, Mr. Henry Wilde, F.R.S., an honorary member of the Institution, generously offered to the Council the sum of £1,500 for the purpose of founding a Wilde Benevolent Fund, to be administered in accordance with the following extract from the Declaration of Trust: "The annual income of the trust fund shall, subject as hereinafter provided, be applied in such manner as the said President and Council or Committee of Management shall from time to time think fit for the benefit of members (exclusive of honorary members, associate members, foreign members, associates, or students) for the time being of the Institution, but principally though not exclusively for those who by their discoveries, inventions, or writings shall have advanced the profession of electrical engineering, and for the benefit of the families of any such members and of any such late members being deceased, and for the benefit of any persons who may have been such members and paid their subscriptions for five years consecutively at least, and of the families of such persons—subject, however, in all cases to the following regulations:—

"(*a*) The income may in any year be applied wholly for the benefit of one person or class of persons, or may be applied equally or unequally for the benefit of two or more persons or classes of persons.

"(*b*) The total amount applied for the benefit of any one member or late member or his family during one or more years shall not exceed one year's income of the trust fund.

"(*c*) There shall be no obligation in any year to apply the whole or any part of the income of that year for the benefit of any person or persons. Any income not so applied may, if and so far as permitted by law, be either retained as income to be added to and applied as part of the income of any subsequent year or years, or may be invested and added to the capital of the trust fund."

This trust was gratefully accepted by the Council, and the said sum of £1,500 has been received and invested. It has been decided that, for the present, the fund shall be administered by the Council.

David Hughes Scholarship.—The Council has the further gratification of reporting that the executors of their revered past-president, the late Prof. David E. Hughes, F.R.S., have announced the bequest by him to the Institution of the sum of £2,000, with the object of founding a David Hughes Scholarship, to be awarded under conditions similar to those under which the Salomons Scholarship Fund is administered. Announcement of the date of the first award will be made when the said amount shall have been received by the Institution.

Local Honorary Secretaries.—The return of Mr. A. P. Trotter to England left a vacancy in the local honorary secretaryship for the Cape and South Africa, and looking to the large number of members in the Transvaal, and to the distance of these members from the previous local headquarters at Cape Town, the Council decided to divide the secretariat into two sections, namely, the Cape, Natal and Rhodesia, for which district Mr. John Denham, M.I.E.E., has been appointed local honorary secretary, and the Transvaal, to which district Mr. J. Hubert Davies, M.I.E.E., was appointed. Two new secretariats have been formed—viz., Italy and Sweden, to which Col. F. Pescetto (foreign member) and Mr. John Henrik Hammar (foreign member) have been respectively appointed as local honorary secretaries. The Council has now, by way of experiment, entered into an arrangement for a year with the Société Internationale des Électriciens, under which the treasurer of each society undertakes the collection of the subscriptions of members of the other society resident in his country. The Council desires to record its cordial thanks to Mr. Trotter for his services as local honorary secretary at the Cape, and especially for his share in the organisation of the Cape Town local section of the Institution, which was being carried on informally and unofficially prior to his return to this country.

Visit of the Institution to Switzerland.—In previous years the Institution has three times held meetings away from London—namely, at the Paris Electrical Exhibitions of 1881 and 1889, and at the Edinburgh Electrical Exhibition of 1890, but otherwise no organised visits have been paid to foreign or provincial centres. During the twelvemonth now closing it was decided to arrange a visit to some of the principal electrical works and installations in Switzerland. Thanks to the efforts of the Reception Committee in Switzerland, and of the Organising Committee at home, and to the untiring labours of our secretary, Mr. McMillan, the Council is able to congratulate the Institution on the success of the visit.

The Council has arranged for a joint-meeting of this Institution with the American Institute of Electrical Engineers in Paris on August 16 of this year, immediately before the opening of the International Electrica Congress; and has also accepted an invitation to visit Berlin in 1901.

Common Seal and Diplomas.—During the period under review the engraving of a common seal was completed. The various investments, with the exception of those in respect of the Salomons Scholarship Fund, have now been tranferred from the trustees to the Institution, and are registered under seal. The Council, being also in a position to issue the diplomas for which provision had been made in the new articles of association, has notified members and associate members that they are entitled to apply for diplomas. As a result, a large number of these certificates has now been issued. To meet a certain demand for diplomas on vellum instead of on paper, the Council decided that any member could demand such a diploma on payment of one guinea, the surplus of receipts over expenditure on account of vellum diplomas being regarded as a subscription to the building fund. Fifty-eight of these vellum diplomas were issued up to the end of 1899, and the subscriptions thus accruing to the building fund amounted to £48. 5s. 2d.

Electrical Museum.—Recognising the advantage that would accrue to the profession from the formation of a historical collection of electrical apparatus, and the increasing difficulty in making such a collection representative of earlier work, the Council has appointed a committee, which is now taking active steps to obtain donations or promises of objects or apparatus not now in commercial use, possessing interest in connection with electrical science and its applications.

The Library.—(*The Report of the Secretary.*)—I have to report that the accessions to the library during the year numbered 57; of these nearly all were kindly presented by the authors or publishers. The presentation of specifications and abridgments of specifications relating to electricity and magnetism has been continued by the kindness of H.M. Commissioners of Patents. The number of visitors to the library during the year has been 555, of whom 50 were non-members.

PARIS INTERNATIONAL CONGRESS OF ELECTRICITY.

The following is the complete programme for the International Congress on Electricity, to be held in Paris on August 18th to 25th. The Congress will be opened on Saturday morning, August 18th, at 10 a.m., in the Palais des Congrès, and will consist of five sections under separate presidents.

Section I.

Scientific Methods and Measuring Apparatus.

(i.) *Units and Dimensions.*—Recapitulation and co-ordination of the decisions of previous congresses.

(ii.) *Methods of Measurement.*—The testing of materials, and the proper specification of their qualities. Insulating, conducting, and magnetic materials. The measurement of magnetic fields, and of the power in alternating and polyphase current circuits. The graphical analysis of periodic functions into their simple components.

(iii.) *Measuring Apparatus.*—Recent improvements in measuring instruments. Watt meters. Phase meters. Hysteresis meters. Oscillographs.

(iv.) *Photometry.*—Secondary standards. Photometers.

Digitized by Google

Section II.

Generation, Transformation, Transmission and Distribution of Electric Energy. Electric Lighting and Traction.

(i.) *Generation and Transformation.*—Progress in continuous current generators with reference to the fixity of brushes. Standardisation of the methods of testing and of definitions, more especially the definitions of maximum current, normal power, fall of potential, and rise of temperature. Comparison of inductor alternators, and other types. Standardisation of frequency and discussion of best practical frequency having regard to its economy and satisfactory working. Compounding of alternators. Asynchronous generators. Parallelling of alternators and effect on regulation of motors. The size of units. Meters and tariffs.

(ii.) *Transmission and Distribution.*—High-pressure lines. Regulations for high-pressure conductors in public roads. The earthing of conductors. Protection against lightning. Automatic earthing of conductors on accidental rise of pressure. Comparison of synchronous and asynchronous motors. The use of condensers.

(iii.) *Electric Traction.*—Progress in traction motors. Comparison of continuous-current, three-phase current converted into continuous-current at sub-stations, and three-phase current. Comparison between traction on rails, motor cars and trains. Air resistance to motion. Maximum pressure allowed by law for traction on urban and suburban lines on railways and canals. Construction of permanent way. Electrolytic action.

(iv.) *Electric Light.*—Luminous efficiency of the arc. Comparison between continuous and alternating-current arcs, open and enclosed. Connection of arc lamps. New incandescent lamps. The lighting of cars and trains.

Section III.

Electrochemistry.

(i.) *Theoretical Researches.*—Conduction through rarefied gases. Velocity of migration of the ions. Chemical action of spark and brush discharge. Organic compounds produced electrolytically.

(ii) *Apparatus.*—Recent improvements in primary batteries. Standard cells. Dry cells. Accumulators with plates other than lead. Choice of a battery for traction, central station, or regulating. Electric furnaces. Miscellaneous appliances used in large works.

(iii.) *Analysis.*—Qualitative and quantitative analysis of metals. Analytical processes in electro-chemical works.

(iv.) *Electroplating.*—Deposition of chromium, aluminium, and zinc. Statistics of the quantity of silver, copper, and nickel deposited annually in various countries.

(v.) *Electro-metallurgy.*—Electrolytic treatment of ores of copper, zinc, lead and nickel. The treatment of mattes. The commercial separation of copper. Comparison of cost of electro-metallurgical with other metallurgical processes. Statistics relating to the production and consumption of electrolytic copper and nickel in various countries.

(vi.) *Large Works.*—Electrolytic manufacture of chlorine and soda, potassium chlorate and sodium chlorate, calcium carbide, and aluminium.

(vii.) *Miscellaneous Applications.*—The production and analysis of ozone and its applications. Preparation of hydrogen, oxygen, glucinium and its alloys, and calcium phosphide. The treatment of sugar juices. Dyeing and bleaching.

Section IV.

Telegraphy, Telephony, &c.

(i.) *Sources of electrical energy.*—Primary batteries, magnets, dynamos, and accumulators.

(ii.) (*A.*) *Overhead lines.*—Iron and steel wires, copper and bronze wires, bimetallic wires, aluminium wires. Porcelain and glass insulators. Wooden poles and processes for preservation. Metallic poles and supports. Cross-arms. Derricks. Methods of erection.

(*B.*) *Underground Lines.*—Gutta-percha, indiarubber, and paper cables. Armoured and lead-covered cables. Methods of construction.

(*C.*) *Submarine Lines.*—The manufacture of cores. The properties of gutta-percha extracted from leaves. Analysis of gutta-perchas. Cores for high-speed transmission. Electrical tests of cores. Protective coverings and armouring. The employment of high-resistance steels. Light cables for great depths. Heavier cables for shore ends. Cables for telephony. Cables with air insulation. Laying and repairing. Cable-ships, tools, sounding instruments, grapnels, and buoys.

(iii.) *Instruments*—(*A.*) *Telegraphic Instruments.*—Multiple instruments and step-by-step multiple instruments. Multiplex phonic apparatus. Fast-speed apparatus. Photographic registration of messages. Relays for submarine and underground lines. Accessories.

(*B.*) *Telephonic Instruments.*—Transmitters, receivers, and repeaters. Multiple exchange switchboards. {Multiples of indefinite capacity. Central-battery multiple switchboards. Automatic switchboards. Branch exchanges. Systems of calling. Relays. Accessories.

(iv.) *Circuits.*—Overhead, underground, and mixed telephonic circuits. Single and double wire circuits. Non-inductive lines. Long-distance telephony. Simultaneous telegraphy and telephony.

(v.) *Propagation of Currents in Telegraphy and Telephony.*—Lines of small and large capacity. Speed of transmission. The order of magnitude of the currents.

(vi.) *Maintenance of Telegraphic and Telephonic Communication.*—Disturbances due to stray currents. Inductive effects of alternating and rectified currents. Insulating material. Nets. Automatic earthing and cut-outs. Protection of stations. Fuses. Effect of thunderstorms. Lightning protectors. Earth currents.

(vii.) *Wireless Telegraphy.*—Different systems. Oscillators, receivers, coherers, and "antennæ." Syntony. Optical telegraphy. Communication with or between ships.

(viii.) *Clocks.*—Automatic winding-up. Automatic regulation. Employment of telegraph and telephone lines for creating a standard time. Adaptation of electric systems to ordinary clocks.

(ix.) *Miscellaneous Applications.*—Calling and signalling apparatus.

Section V.

Electrophysiology.

(i.) *Production of Electricity by Living Beings.*—So-called "currents at rest" in the tissues, nerves, muscles, glands, &c. "Active currents" or "negative oscillation" in the same tissues. Currents from the special organs of electric fish. Methods and instruments for the study of these currents.

(ii.) *Effect of Electricity on Living Beings.*—Effects of the form of the exciting wave; characteristics of excitation. Electrification by static machine, battery, induced currents, sinusoidal currents, undulatory currents and high-frequency currents. The processes of applying, and the methods of generating these currents.

(iii.) *Measuring Instruments and various Physiological Effects.*

(iv.) *Dangers of Different Forms of Electric Energy.*—Death by electricity. The treatment of persons suffering from shock.

During the Congress, visits will be made to the various electrical installations in Paris, in which only members will be allowed to take part. Names of those desirous of membership should be sent to M. Paul Janet, 14, Rue de Staël, Paris, one of the secretaries of the organising committee, and the subscription (20fr.) should be sent to the treasurer, M. Léon Violet, 20, Rue Delambre, Paris.

THE ELECTRICAL EQUIPMENT OF SHIPS OF WAR.*

BY C. E. GROVE.

(*Concluded from page 179*).

Electric Ammunition Hoists.—For serving the 6in. and smaller guns these are in use in many navies. The "Powerful" and "Diadem" classes of cruisers were fitted with them, but the later English ships are fitted only with hand gears. In the United States and Japanese ships they are usually found. The apparatus consists of a quick-running motor of 2 H.P. to 5 H.P. geared in some way to a light whip or chain tackle for lifting small parcels of shot and shell at high speed. The motors must be so controlled that they start, stop, and reverse very quickly, with automatic brakes to hold them as soon as the current is switched off, or else the motions must be effected by clutch gears thrown in and out of connection with a continuously running motor. The latter arrangement is used by Messrs. Armstrongs with friction gears. Fig. 36 shows the arrangement in plan. The motor shaft being in rotation, a vertical lever acting at O along the axis of the shaft puts either of the speed cones A or B into gear with C, thus driving sprocket wheel W1, over which an endless chain runs, passing also over a fixed sheave at the top of the hoist. The cones A and B being out of gear, and therefore running free, the cartridges or projectiles in a bag are hooked on to the chain at the bottom, the friction gear brought into action, and the ammunition rapidly hoisted. Then, while this bag is being unhooked at the top, another round is being hooked on the other side of the chain at the bottom, the cone gears are reversed, and the second charge hoisted, and so on. There is an automatic arrangement for throwing the cones out of gear at the right time for each lift; there is an alternative hand gear working through the sprocket wheel W2, with arrangements for preventing both the hand and power gears being in operation at once, and other details not shown in the sketch.

Summing up the power requirements enumerated in the foregoing paragraphs we get:—

—	Total motor capacity installed, including duplicates.	Maximum demand for power, duplicates excluded.
	E.H.P.	E.H.P.
Ship ventilating fans	40	40
Engine- and boiler-room fans	100	100
Furnace air-blowing engines	200	200
Steering engines	400	200
Forward capstan	120	120
After capstan	50	50
Boat hoists	100	100
Coal hoists	100	100
Ash hoists	20	20
Workshop engine	5	5
Air compressors	200	100
Turret motors	500	300
Ammunition hoists for 6in. and smaller guns	50	50
Totals	1,885	1,385

* Paper read before the Institution of Electrical Engineers, April 26th.

If these figures err, they err on the large side. In working out details, savings both in power and weight could probably be effected. There are no conceivable circumstances in which the whole of these machines could work simultaneously. The worst conceivable case supposes that in time of action all the gun-working machinery, air compressors, furnace engines, ash hoists, ventilating fans, and steering engine would be at work together. Then the aggregate horse-power demanded would be, according to the above figures, 1,015 E.H.P. input to motors = 760 kw. The lighting of the ship would involve 50 kw., and the searchlights—if it be conceivable that all this mechanism could be employed at night when searchlights were wanted—a further 50 kw. or 60 kw. But, taking into account the fluctuating demands of current made by the motors, and the fact that it is hardly physically possible for everything to be working at the top of its load at precisely the same instant, about 600 kw. output would meet all requirements and cover distributing losses, while 800 to 850 kw. installed in the ship would leave an ample margin of spare plant in all ordinary circumstances. Now this is an equipment not at all unlikely to be called for in the future. It will not come all at once, but it may come sooner than many would allow. What should be the arrangement of plant and system to successfully cope with it?

It seems clear that an installation of 800 kw. is not to be provided by the multiplication of 50 kw. sets. Yet it will always be desirable for battleships to carry a few sets of 50 kw. size—(*a*) for lighting and ventilation when nothing else is doing; (*b*) for working searchlights; (*c*) for regulation of turret and steering motors, should that method not be superseded by something better. But after 200 kw. or 300 kw. are reached, it would be wise to introduce sets of 150 kw. or 200 kw. capacity—the latter for preference. Then for an 800 kw. installation we might well have three sets of 200 kw. each and four sets of 50 kw., there being enough sets of each size to form an efficient reserve. It would be most undesirable to introduce a lot of intermediate sizes.

In regard to the electrical system to be employed for distribution, two questions at once arise—(*a*) whether continuous currents should be employed throughout, or whether polyphase currents should be introduced for the motors; (*b*) whether the existing standard of 80 volts should be retained.

(*a*) In view of the fact that machinery on board ship gets very little attention, it has been urged that polyphase motors should be used on ship-board, because they do away at once with all commutator troubles. But it is to be urged that well-built modern continuous current motors give next to no trouble at the commutator, and that even the polyphase motors would require collecting rings and starting resistances. But the chief objections to the introduction of polyphase machines on board ship are the disadvantage of having two systems of distribution in the ship, and the introduction of the third cable. Possibly the relative advantages and disadvantages are pretty evenly balanced. At any rate, polyphase motors have actually been introduced by the Austrian Navy on their coast defence ships "Buda-Pest," "Wien," and "Monarch," the currents being generated by composite machines which give continuous currents from a commutator on one end and three-phase currents from collecting rings at the other end of the armature.

(*b*) The question of the voltage standard is of greater difficulty. 800 kw. at 80 volts means 10,000 amperes to distribute, which represents a very formidable amount of cable work. If the pressure were doubled, the currents would be at once reduced to 5,000 amperes and the saving in weight and cost of cables would be material. The United States battleships "Kearsage" and "Kentucky" are wired on the three-wire system with 160 volts between the outers. The motors are in general arranged on the 160-volt mains, though a connection is usually taken from the middle wire to provide for changes of speed by switching the motor on to the low-voltage mains. Searchlights and incandescent lamps are arranged on either side of the system to make an approximate balance, as is usual. The results of experience in these ships will be watched with great interest. The author is a little diffident as to the introduction of a three-wire system on board ship, and would rather prefer a direct circuit of 160 volts, for both lamps and motors. Indeed, having got so far, one might as well accept the 200-volt standard at once. Searchlights in such an installation could be operated with very little complication through "series-parallel" switches, which, in the one position, would put two searchlights in series, and in the other position put each searchlight on separate circuit on the mains, with the addition of a resistance capable of absorbing the remaining volts. With automatic lamps, this should be quite feasible, and any difficulty attending the use of so large a resistance as would regulate the arc down from 160 or 200 volts would probably be less than the difficulty of maintaining a balance of voltage on the two sides of the three-wire system when the searchlights worked intermittently, if that system were used. Of course the use of 200 or even 160 volts generally would impose a greater strain on the insulation of the cables and fittings than is now experienced, and would require some improvements in the design of fittings established; but there are no serious difficulties here.

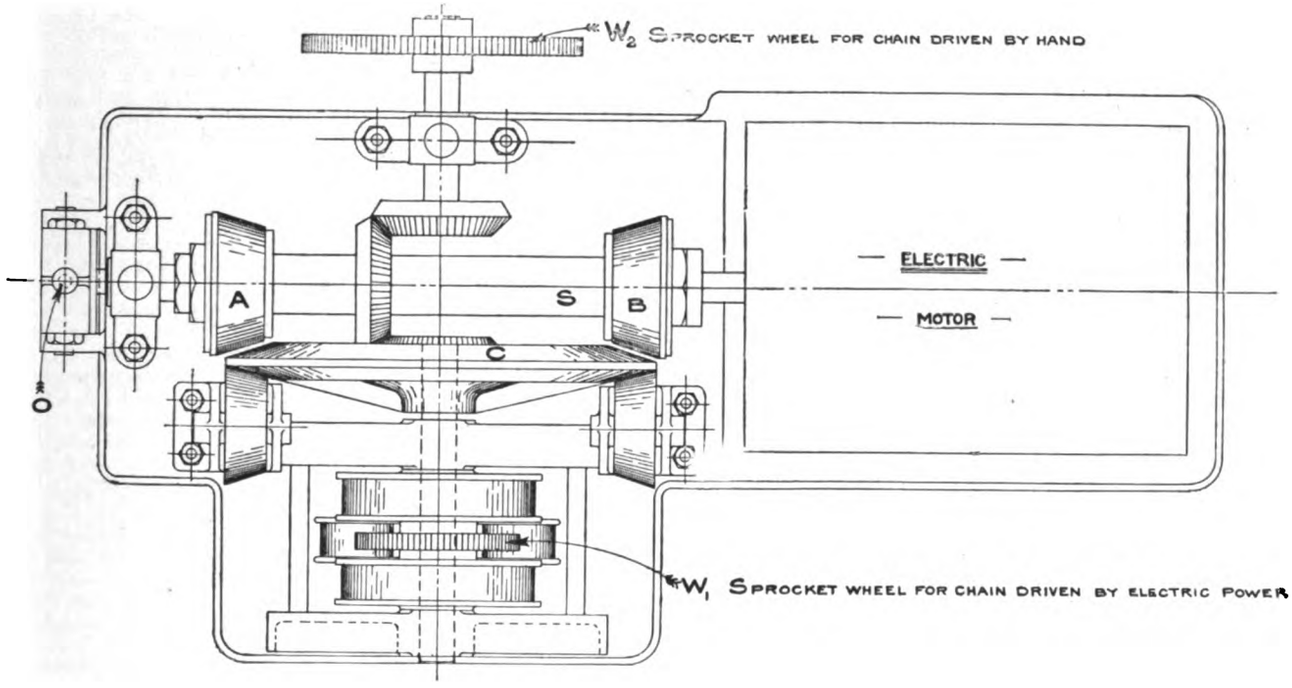

FIG. 36.—Electric Ammunition Hoist Gear (Sir W. G. Armstrong, Whitworth & Co.).

Instead of the Tree system of wiring as at present adopted, all the main cables should be run in rings round the several decks back to the switchboard; through connecting boxes being provided at intervals of 100ft. or so, for rapid disconnection and testing. With such an arrangement a circuit might be injured or shot away in any place without affecting the main supply of current. Separate ring mains for lights, searchlights, and motors should, of course, be used with throw-over switches to connect one to the other on special occasions. It would be desirable to divide the main switchboard into two parts in the machinery room, connected together by switches which would form the closing links of the ring mains, the object being to avoid the possibility of a total breakdown by fire at the main switchboard, which always exists when all the cable connections go through one narrow neck. Of course, all the casings and other woodwork now used about switchboards should be rigorously abolished. The cable distribution should be expressly taken into account and allowed for in the design of the ship, proper trenches or culverts being provided for the cables. At present no such provision is made, and it is often a matter of considerable

Digitized by Google

difficulty to find suitable runs, especially where cables have to pass watertight doors and the like.

Returning now to the generators, the question arises as to the possibility of providing the necessary weight and space. 800 kw. in generators of the existing type with double-acting engines, at speeds of about 400 revs. per min., would involve with steam and exhaust connections about 80 tons. This is the only increase in weight, as the motor weights balance out; the additional weights mentioned in the detailed descriptions of the motors above being counterbalanced by the saving which would be effected in the turrets if electrical machinery were substituted for hydraulic for gun working. The weight of the main hydraulic equipment—25 tons—is a credit against the generator weights. There would indeed be a slight saving in the weight of distributing cables and switchboards as compared with the auxiliary steam and exhaust pipes now required for the services in question, but it would not be much. Approximately 55 tons of additional weight, then, has to be carried. In discussing the question of coal consumption, it was shown on the figures there stated that the substitution of electricity for steam for all the auxiliary services would result in the saving of 262 tons of coal for every 25 days' steaming. This figure was calculated upon data assumed to represent the best possible conditions. Some of the engine and boiler-room pumps have been assumed to remain steam-driven, but if electric driving be applied to the services enumerated, and if only one-half or one-third of that estimated saving were realised, there would still exist a strong *primâ facie* case for the adoption of electrical power.

The weight of generators might be materially diminished by the employment of single-acting engines driving dynamos at higher speed, and still more by the adoption of turbine-driven sets; the weight of the units mentioned could be done with Parsons' turbo-generators, including condensers, for about 60 tons. Single-acting engines and turbines have both been used in the Navy; unfortunately both have failed, and, as a consequence, both are at present looked somewhat askance at for the purpose. They require dry steam: hence one of the principal sources of difficulty in the old arrangement, but one that should not occasion much trouble in the new. This consideration, coupled with the very great improvements that have been made in both since the days when they were used in the navy, may bring them into service again.

The space required for the generators for the power mentioned would lie between 800 sq. ft. and 1,000 sq. ft., whichever of the three systems be adopted. It is not easy to find this room in an existing battleship; but on the hypothesis, the main hydraulic engines would not be wanted, and the space occupied by these two rooms would be available. If in consequence of savings on account of efficiency less coal were carried, though a saving of weight would be appreciated, little space would be added for the purpose of generators. Possibly the change to electric driving might be carried out in conjunction with some other change in the disposition of the *matériel* in the ship. For example: there are not wanting critics who consider that it is out of place in these days for ships of the fighting line to carry torpedoes. Should such a view obtain official support, a room equivalent to one of the existing submerged torpedo rooms would make an ideal generating station. Its locality would be, for preference, immediately adjoining the forward boiler-room bulkhead, so that the steam connections might be short and direct.

The electrical equipment of ships of war is the product of many hands and brains. Naval authorities do not as a rule design—they formulate requirements, and the engineering experience of the country is laid under tribute to meet those requirements. Hence it comes about that much of the apparatus employed is of a proprietary kind, and the author has to acknowledge the kindness of many firms and friends who have allowed him to describe their apparatus and inventions. These have already been mentioned by name in the Paper. He is also under obligations of a more general kind, and is pleased to acknowledge here his indebtedness to the Lords of Her Majesty's Admiralty for permission to describe parts of the equipment of H.M.S. "Albion," and to make various references to Admiralty specifications; to the Naval Attaché of the Imperial Japanese Embassy, for permission to refer to the equipment of the battleships recently built in this country for the Japanese Government; to the General Electric Co., of Schenectady, U.S.A., for the photographs illustrating American apparatus; to Messrs Sir W. G. Armstrong, Whitworth, and Co. (Ltd.), for permission to include particulars relating to the electrical side of their naval ordnance work; and to the Directors of the Thames Iron Works Shipbuilding and Engineering Co. (Ltd.) for permission to make general use of the information in their possession.

DISCUSSION.

Capt. CREAK, referring to the question of the effect of the wiring of a ship upon the compasses, said he only knew of one instance in which bad effects had resulted, and this was in connection with the automatic projector in Fig. 18A. In this apparatus the leading wire was connected to one arm and the return to the other. The consequence was they got a deflection on the compasses of 2deg. in one direction and 2deg. in the opposite direction. But this had been easily remedied by leading both wires to one arm of the projector. The greatest sinner on board ship, in the matter of the effect upon the compasses, was the dynamo, and he had often asked dynamo builders and designers to build a dynamo without an external field. With ironclad dynamos he had got a deflection of 2deg. or 2½deg. at a distance of 20ft. away from the machine.

Mr. SYDNEY EVERSHED thought Mr. Grove's Paper gave a very good account of the present position or rather transitional position in which electricity is in the navy; it enabled us to see that our navy was not so very far behind the navies of the rest of the world. There was often a sort of feeling that in the British navy every novelty was passed as a matter of course, but those who had had anything to do with introducing novelties into the British navy could say that this was not the case. It had to pass the ordeal of the three great branches into which the administration of the navy was divided. It was clear, from Mr. Grove's Paper, that the next few years would show an enormous difference in the manner in which electrical work was carried out. At present, if they looked at any warship from an electrical engineer's point of view, they were struck with the rather costly electrical equipment. All the dynamos, engines, cables and everything else were of the best possible quality, but the manner in which they were installed rather suggested that the whole electrical scheme was an after-thought. He was of opinion that the author's suggestion of a power station on board each first-class cruiser or battleship was the right one, and in a few years' time they would see a central electric station properly designed and put into the right part of the ship under the protective deck. It had been very truly stated in the Paper that the development of the electrical equipment of the warship had been the product of many minds and men's work. His own part in the work was chiefly in the direction of establishing communication, and he could confirm what Mr. Grove had said as to the unsatisfactory nature of speaking tubes. It is almost impossible in many parts of the ship to make any use of these pipes. Capt. Creak had referred to the leakage from ironclad dynamos, and at the time it was proposed to use this kind of machine he felt perfectly certain it would be a failure. He even ventured to put his views before the Admiralty in an unofficial way, but he did not think it had much effect. It was tried, and he was not at all surprised to hear that it only diminished the compass error by about half. Although it was possible to shield a dynamo to some extent, they could never entirely get rid of the effect of a coil by putting iron round it, and he was glad to see the Admiralty were introducing the four-pole type of dynamo. This was the true way out of the difficulty, because it made the dynamo astatic.

Mr. R. E. B. CROMPTON said he was going to play the naughty boy again. A previous occasion on which he had done this was in discussing a Paper read some seven or eight years ago before the Mechanical Engineers at Portsmouth by an official of the Admiralty describing electricity in Her Majesty's navy, and in daring to criticise the matter he had so annoyed the officials that he did not get an Admiralty contract for years afterwards. But as he had since been thanked for what he had said he did not mind. He considered the state of the navy with regard to the use of electricity a disgrace to the profession. They were very much indebted to Mr. Grove who had put his Paper in a very readable form, a form which helped him (Mr. Crompton) very much in putting forward criticism for what it might be worth. He would first point out that our Admiralty did not have much to do with the introduction of electric lighting on board ship. This had to be done for them by English contractors for foreign Governments. The first ship fitted throughout was a Brazilian cruiser, and the only reason why the British Admiralty followed suit was that one of their officials was consulting engineer then for the Brazilian Government and he had thus had an opportunity of thoroughly studying the arrangements, which were promptly adopted in Her Majesty's service. Mr. Grove mentioned that even now the electric motor was looked upon with suspicion, but he asked them if it was commoner for an electric motor to break down than for a steam engine, at any rate he had never seen one break down without it had given notice that it was not receiving proper attention, and the cases in which an electric motor broke down without any warning were so rare as to be unknown. With regard to hydraulic power he stated that he had an hydraulic lift in his own house for 10 years and he had known it in the case of a hard frost to be a source of anxiety to the family. He had been telegraphed up to the Midlands on account of three hydraulic fittings splitting one night, and he did not see why, on Her Majesty's ships in extreme latitudes, difficulties of the same kind should not take place. In conclusion he mentioned a statement at the end of the Paper to the effect that both single-acting steam engines and turbines had been tried for driving the generating sets but that both had failed, and as a consequence were looked at askance. While there were others who could speak about the turbines, he could say something about the single-acting engines. Was it not a scandal that the single-acting engine—the greatest friend to the electric light industry—had been kept out of the navy?

Mr. A. E. RICHARDS thought that Mr. Crompton had really got quite outside the Paper at times. Mr. Crompton surely did not mean them to take his statement seriously, that he did not have another Admiralty contract for some time because he had criticised their projector? The Siemens' projector was perfect, and it had been tried in the navy for a long time; but the reason it was not used at present was not because it was inefficient as a projector, but because the people who used it did not consider an automatic projector was required. With regard to the matter of dynamos, he said that of course, a good many years when the Admiralty specification for dynamos was first published it caused a good deal of discussion, the chief thing criticised being the temperature limit; in fact, it had not finished being criticised yet. It was stated in the Paper that the Americans adopted a lower temperature limit; but he might say that during the many years from the first introduction of electricity in the navy, he had never known a dynamo bought

Digitized by Google

under the conditions of the British Admiralty specification to fail. Most of the troubles experienced had been on the engine side, and they had some dynamos at present working which had been installed in 1886, and which had outlived the main engines of the ships. This quite agreed with Mr. Crompton that a dynamo or motor never broke down, and it should not, as there was nothing in it to break down. Coming to the question of the electric lighting of ships, he said he did not understand one little clause in the Paper describing the glands for making the bulkheads watertight, and which stated that "they cannot be drawn back." His own idea was to have a cable which never wanted drawing back. In the matter of communication, he said they all knew that voice pipes were not very satisfactory, but until they got telephones in good working order he did not see how Mr. Evershed was going to improve the voice pipe system or any other system.

Mr. A. A. C. SWINTON did not altogether agree with what Mr. Crompton had said. His own view of the matter was that up to a certain point electrical arrangements for the distribution of power on board ship were exceedingly good, but they were not applicable in all cases, and more especially with regard to the training of large guns, hydraulic arrangements were very much better. In training large guns or heavy weights generally, a slow, steady motion was wanted, and this was obtained by hydraulic machines, with extraordinary accuracy and precision, in a way that he did not think would ever be attained by any other kind of machinery in which there were rapidly revolving parts (inevitable in the case of a motor) besides the effects of momentum and a great complication in gear and brakes. His only other point was in connection with the question of turbines which had been mentioned in the Paper, as he had been the first to put one on board ship for the purpose of electric distribution when with Messrs. Armstrong. Mr. Parsons, in conversation with him, had stated that steam turbines were not suited for small power, and that it was very difficult to make small turbines economically, and he thought this was the reason the Admiralty had not continued the use of them. Besides this, at the time of their introduction, the electrical equipment of the ship was a very small part of the whole, and it was very difficult to get the chief engineer to take sufficient pains to learn the details of a new machine which they only considered a very small part of their business. Again, in some cases the turbines were placed transversely across the ship instead of longitudinally, and if they put turbines working at high speeds transversely they got very large strains.

Mr. A. J. LAWSON said that in the description of modern practice, as described in Mr. Grove's Paper, one thing which had struck him was the departure from the "central station" method in the lighting of ships of war. The generating sets were distributed all over the ship, often a long way from the main engine rooms and from each other. Consequently, there was a great length of steam piping, with all its attendant losses, besides complication of the wiring, in which ring mains were a necessity. Again, the Admiralty for very inadequate reasons had adopted a voltage which was used by nobody else—a standardisation of the wrong kind. The sooner they went to 100 volts, or even 200 volts, and got machines which did not have to be specially wound, the better it would be. This increased voltage and the return to "central station" methods on board ship would reduce the massing of cables shown in some of the illustrations, and produce better results in every way.

Mr. C. E. GROVE, in replying, drew attention to Mr. Evershed's remark that he did not think the Admiralty backward in these matters, while Mr. Crompton thought they were disgracefully so, but really the truth lay between these two statements. His Paper certainly did show that in many respects foreigners made electrical applications more elaborately and with more enterprise than was actually done in the British navy, and he thought they were too conservative. There was room in a country like this for more liberality and enterprise in actually trying things. His experience certainly agreed with the remarks that had been made that if there was any difference between the reliability of a steam engine and a dynamo or motor, the advantage was with the electrical machine, but it was extremely difficult to get engineers who were marine or mechanical engineers without electrical training to believe it. One remark of Mr. Richards, he thought, called for answer, and that was that they should build their electrical equipment to suit the ship. He ventured to say this was utterly wrong, and he would even go further than that. Ships were, and have been, and would be built around various objects. Again and again ships were specially designed round guns; the design of the whole ship was made subsidiary to the attainment of certain qualities in gun fire. Within the last few years the British Admiralty had designed and built ships around the Belleville boiler, and if we could only get the British Admiralty to believe they would get better results in efficiency, reliability, economy of coal, and general cleanliness and convenience by the introduction of an electric power station on board, there was no earthly reason why a ship should not be built round the electric power station. He was proud of the simplicity and beauty of hydraulic machines, and the reason why this had been brought to the state of perfection it had in this country was that the principal firm of British gunmakers was Messrs. Armstrong, Whitworth and Co., and they were also our leading firm of hydraulic engineers. The two systems existed in the same company, and nothing was more easy than to develop the two systems together, but if Armstrong's had been an electrical firm the result might have been the reverse. At the same time, on the "Brooklyn," as mentioned in the Paper, the 13in. turrets had been started and stopped electrically very frequently, and with satisfaction, and such results did not stand alone. The Ward-Leonard system of control seemed to lend itself perfectly to the adjustments in minute fractions of degrees, and the momentum effect was almost nil. Mr. Mordey had just told him that some such method of control by the use of generators and motors combined was used over and over again in lifts, and was quite successful where momentum effects had to be dealt with, and where quickness of action was essential.

PARLIAMENTARY INTELLIGENCE.

NORTH METROPOLITAN ELECTRIC POWER SUPPLY.

The Parliamentary inquiry into this electric power scheme, which principally affects the northern suburbs of London and the adjoining outside districts, is proceeding before a Committee of the House of Commons, consisting of Mr. H. A. Brown (Chairman), Mr. Trevelyan, Mr. Rutherford, and Mr. Murnaghan. The first sitting was held on May 24. The opponents of the measure include the District Councils of Wood Green, Hornsey, Walthamstow, Hendon, Edmonton, Tottenham, and Southgate, the County Councils of Hertfordshire and Middlesex, and the Harrow Electric Light and Power Co.

Mr. LITTLER, Q.C., for the promoters, said none of the petitioners raised in the least degree any question of principle with regard to the desirability of supplying electric power, and it was only with regard to the particular circumstances in which the company proposed to supply that any issue was raised. The company promoting the scheme had its origin in the important principle laid down by successive Parliamentary committees in every conceivable class of circumstances that the larger the works supplying a district with electricity and the more varied the demands they had to meet, the better and the cheaper for the consumer; firstly because electrical energy can be more cheaply produced on a large scale than on small scale; and, secondly, because the more varied the purposes to which the current so generated was put, the better for everybody by reason of the reduction of price. In the district proposed to be served under the bill there was already a considerable area devoted to manufacturing purposes. It was proposed to include in the area of supply the eastern half of the county of Middlesex and a considerable portion of the county of Hertford and a small part of Essex. The districts scheduled included Enfield, Waltham Cross, St. Albans, Friern Barnet, Southgate, Hornsey, Wood Green, Finchley, Hendon, Harrow, and Wembley. In some of these places there were light railways and tramways on which it was inevitable that electric traction would be used in the future, and in others there were large establishments, such as small arms factories, powder factories, lunatic asylums, and so on, to which an electrical supply would also be most advantageous. Consequently powers were sought to lay down electric mains in the streets and roads of these districts, and the company undertook to supply all authorities, companies, bodies, or persons entitled to be so supplied with energy for lighting and power. The promoters asked only for power to supply those people who had Parliamentary authority themselves to sell electricity, and not to supply any railway company, tramway company, or other persons who were merely consumers. The first-named bodies would have the whole of the retail distribution in their own hands, and would fix the price to be paid by the consumers; instead of each having their own works, the company would provide the power at the cheapest possible rate. The only compulsory powers over the districts in question sought by the bill was the power to open up the streets and roads. The local authorities might themselves dictate to the company the routes which the cables should take, and might themselves, if they chose, open up the streets and lay the cables, charging the company with the cost of the work. The only difficulty with the company was that they must be subject to some local authority, and there was a difference of opinion as to what authority it should be. If they accepted the views of the Middlesex County Council they would be subject to two authorities, the urban district council and the county council, which would be rather awkward if one required one thing and the other required another. The scheme before the Committee was not in any way a speculative one, and it would be of the greatest possible value to consumers of electricity whether for power or lighting. It was practically permissive in its character, the only compulsory powers sought being those which had been conceded by Parliament over and over again of going through certain districts for the purpose of supplying others.

Mr. S. Z. DE FERRANTI, examined by Mr. Balfour Browne, Q.C., said the essential feature of the scheme before the Committee was the provision of a wholesale supply of electrical energy in place of having a multiplication of small generating stations. There were in existence in certain places large works with ample power during the whole 24 hours, where they probably had such a good load factor that they would not need to come to the Power Co., but there were very few such cases in which consumers would not avail themselves of a public power supply if it was obtainable. In most cases manufacturers only wanted power for a certain time, and it was more economical to get it from a power generating company which had various loads. A number of tramway and light railway companies would no doubt be excellent customers of the power Supply Co., as it would be most advantageous to them to get an electrical supply just wherever it was wanted without having to engage in an electric generating business as well as that of running cars and trams. Supposing that the Power Co. supplied these concerns, they would have a considerable load factor throughout the day, and in the evening also. This would enable them to supply electricity for lighting, say, in Hertford or St. Albans, or other town at a much cheaper rate than they could otherwise supply it, if they had not tramways on their system, without detriment to the supply to the tramways, and also enable them to greatly reduce the cost of supply for electric light purposes. Then having got both these large customers they could supply manufacturers at a very much lower price than the manufacturers could supply themselves, because the Power Co. would have a good load factor. As had been explained, the promoters did not want to compete with the local authorities, but to supply the local authorities with electricity, which they in their turn could supply cheaply to the manufacturers. The Power Co. would merely generate and transmit the power to those who would take it wholesale, namely, the authorised companies and local authorities who would provide both the capital and

Digitized by Google

the labour for distributing the current to the individual consumers. Instead of the local authorities and tramway companies each having their generating stations, and distributing electricity to the consumers, they would take a supply from the trunk mains of the Power Co. If both the generating station and the distributing plant were in one hand, the consumers would merely have to pay to one set of persons what he would otherwise pay to two, in fact he would only pay to the distributing authorities.

On what load factor have you been calculating in this case?—On a 25 per cent. load factor derived from tramways, lighting and power. The 6,000 kw. which the company were proposing to lay down in the first instance would by no means meet the demand which would arise in the area of supply. It was simply something to begin upon. For the purpose of arriving at that load factor the company would have to divide the 6,000 kw. as follows:—1,300 kw. for traction, 2,500 kw. for power, 2,200 kw. for lighting. The following were the load factors in each class of demand:—

Estimated maximum demand	6,000 kw.
Capacity of generating plant	8,000 kw.
Capacity of boiler plant	13,000 H.P.

Estimated load factor 25 per cent., made up as he had just stated. The estimated units generated would be 15,300,000, and the estimated units sold 13,000,000.

You can, of course, increase that 6,000 kw. to any extent, but it would be probably always in the same ratio for electric railways and tramways, power and light?—Undoubtedly we can increase it. It would be impossible to say that it would follow exactly the same ratio, but I anticipate that it would never be less favourable.

You put down the capacity of the generating plant at 8,000 kw., allowing 2,000 kw. for a reserve, and a very ample reserve?

The CHAIRMAN: What is the power of 13,000 H.P. reckoned in kilowatts?—10,000 H.P. if you could put it in that way. Boilers only measure horse-power.

Mr. BALFOUR BROWNE: It would rather astonish a boiler to talk to it about kilowatts?—It would, but it would not be unreasonable. £59,800 was the estimated cost of the plant which would transform the steam power into electrical energy. In addition to this there were engines and generators, £80,000, or £10 per kilowatt; switchgear, £16,000; lands, buildings, foundations, chimney, coal stores, and general building work, £40,000; bringing the total up to £195,000. Next came the cost of transmission, which would vary according to circumstances. Mains laid and jointed complete £13,000, and £30,000 for the transformers and transformer chambers, making altogether £355,000, to] which must be added engineering fees, cost of promotion, procuring the capital, and the necessary powers, which he had put down at the round figure of £34,200, making altogether a gross total of £390,000 for the 6,000 kw. The working cost would be £22,000, the cost of coal being estimated at 0·40d. per unit; oil waste and stores, 0·04d.; depreciation, repairs and maintenance, £14,200, being 4 per cent. on the capital expended on plant and machinery; wages of workmen, £5,000, or 0·09d. per unit; rates and taxes, £3,000, or 0·05d. per unit; and management running expenses and directors' fees, £5,800, or 0·11d. per unit. The total expenditure for generation and distribution to the various consumers would be £52,200, or 0·95d. (just under a penny). The very tempting price of 1½d. would bring in a revenue of £81,250 as the result of selling 13,000,000 units, from which would have to be deducted the cost of generation and transmission £52,200, leaving a net profit of £29,050, or 7 per cent. upon the total capital, with a small amount of £1,750 to carry forward. The mode of working proposed under the scheme was the two-phase alternating current. This current would be transformed down to the 500-volt continuous current required for the tramways. The generation would be effected at 10,000 volts pressure. The provision of a third or reserve cable would obviate any fear of part of a district or area being cut off from the supply through failure of the cables. Two cables would be used normally, and the third would take the place of either of the other two in case of accident or repairs, and be laid in solid bitumen. The whole of the materials used in the cables were of the most permanent nature. The insulation was made of paper and oil, both of which were most permanent. He was perfectly certain that cables like these would be as good fifty years hence as when they were first put down.

By the CHAIRMAN: Starting with the copper in the cables for transmitting energy such as would be used in the first instance, there would be no depreciation of that copper from the current-carrying capacity point of view. The conductivity would not decrease, and the insulation would not become less useful.

By Mr. WORSLEY TAYLOR, Q.C.: Each of the cables would be equal to the transmission of 2,000 H.P. As to safety a pressure of 10,000 volts was contemplated. As far back as 1888 the Board of Trade had sanctioned this pressure throughout the streets of London.

By Mr. CLAUDE BAGGALLAY, Q.C. (representing several of the opponents of the Bill): The details of the scheme were the same as in the Durham Bill, modified, of course, by the change of circumstances as between the two districts.

Mr. BARTLEY DENNIS (for the Harrow Electric Light and Power Co.): Where a power has been already established in a district, and is doing well, do you think it right that a powerful syndicate such as yours should be allowed to come in and compete?—We introduce no competition.

Mr. HUTCHINSON (for the Walthamstow Council): Supposing that a tramway company or light railway company, authorised to use electrical energy, obtain a supply from you, could they not use it for the purpose of lighting their own premises?—Certainly; instead of making it for themselves they could buy it from us.

Mr. GEO. CORBLE, clerk to the Lea Conservancy Board, examined by Mr. Littler, Q.C., said the scheme of the bill would be of great benefit in developing the business of the river Lea on the understanding that the powers sought do not include the distribution of electricity to the consumer, but only the supply in bulk to authorised undertakers; that no power is taken to break up streets for the purpose of supply to the consumer or save for the purpose of getting to the point where the supply is given in bulk to the authorised undertaker, or that the street work if required can be done by the authority at the company's expense; that the local authority is to be left to consider the route proposed for the through mains, and that the object of the bill is to reduce the cost of electric energy, and to limit the number of generating stations required in a given area. Every year (said witness) more and more people were looking out for factory land on the borders of the Lea, tempted not only by cheap carriage, but by the comparative cheapness of the ground. To these places an efficient supply of electricity would be a great advantage, and he also had in mind that some day barges might be propelled by electricity if power could be obtained cheaply.

Mr. J. W. SWAN, F.R.S., examined by Mr. Worsley Taylor, said that year by year there had been very great development and progress in the direction of increasing the area of economic supply of electricity, mainly owing to the increase in the district over which it had been found by gradual experience that electrical energy could be transmitted economically. For instance, in 1877, by the Jablochkoff system, 20 or 30 lamps could be run from one dynamo. Shortly after that the Swan incandescent lamp was invented, and in about the year 1880 it was found possible to distribute electricity for something like a mile and a half from the generating station. Even Sir Wm. Siemens was at one time of opinion that for the electric lighting of London a separate generating station would be required for every square mile proposed to be lighted, but now it was agreed by all electrical engineers that the position was entirely changed, first of all by the fact that by means of the high-tension dynamos and cables described by Mr. Ferranti it was possible to transmit energy economically, having generated it at a central station, over a large number of miles. He agreed that electricity could be transmitted at such high pressures as were contemplated in the scheme before the Committee with perfect safety. Very great advantage would arise from the fact that a day use for power purposes and traction as well as a night use for lighting could be found and arrangements could be made for facilitating that combination of uses. It would be a much better arrangement to have one generating station and to distribute the power generated at that station to the neighbouring districts, rather than to have a number of small stations distributing within their own small areas. He was not sure that the proposals in the bill would be of any direct advantage to the Edison and Swan Co., except that, being large employers of labour, it would be a much pleasanter thing for their workpeople if electric light was supplied in their district. There was also a remote possibility that they might themselves take an outside supply of electricity for driving machinery if they ran short and there was a neighbouring electrical station supplying electricity very cheaply.

Cross-examined by Mr. FORBES LANKESTER (for the Wood Green District Council): Do you agree that 5,000 kw. is a fair economical unit?—I do not think that rule could be stated without reservation. I should not call a station generating 5,000 kw. a very small station. It would not make much difference in point of economy of generation whether the electricity was generated by a combination of local authorities or by a single company. At the same time it was rather difficult to imagine a small local authority extending its operations over a wide area when a company was proposing to do the same thing.

By Mr. HUTCHINSON: An alternating current of 10,000 volts pressure is not the most advantageous current for driving motors, is it?—It would have to be transformed.

Light railways and tramways generally take their current at about 400 volts, do they not?—Yes.

And they prefer to have it continuous, and not alternating?—Yes. It is part of the scheme before the Committee to supply electricity at such a pressure for traction purposes.

Further general evidence in favour of the scheme having been given,

Mr. J. S. RAWORTH said he had been paying great attention to the subject of electrical transmission of power cheaply and effectively, and had come to the conclusion that the scheme before the Committee would throw open a considerable area in the neighbourhood of London suitable for the erection of works both for electrical and for manufacturing purposes. If arrangements could be made whereby power could be acquired from a large supply company or works it would be almost a living profit to some manufacturers—that is, the saving in power would be so great as almost to keep the manufacturer in food and board and lodging. He was satisfied that small local authorities, if they could take their power from large works such as those proposed, and distribute the power themselves, would be able to supply customers much more cheaply, and get a very much more extended sale for electricity and make a satisfactory profit for themselves.

Have you found that if generation is carried on on a large scale the saving of cost is in itself more than sufficient to pay the whole capital cost of distribution?—The saving in capital cost of the installation is enough to provide for distribution.

What is the cost of distribution? Is it very small when the distance does not exceed 6 miles?—Very small indeed, if properly used.

You estimate that where the load factor exceeds 25 per cent, and the distance is not more than 6 miles it may be even less than $\frac{1}{10}$d. per unit?—Yes.

It has been suggested that if you have a main from your generating station at Enfield to St. Albans you cannot take off any electricity on the route; is that so?—No, you can take it off.

Is the scale of maximum charges so worked out that, as near as possible, the consumer shall pay a price based on the cost of generating his own particular supply?—It is made with the intention that a man taking an expensive supply pays a higher price than a man taking a cheaper supply.

Digitized by Google

Obviously, if you have a uniform tariff, the effect will be that the consumer with a low load factor would be supplied at a loss, while the man with a high load factor would be unduly taxed to make up the loss?—That is the defect under which no great expansion of electrical energy takes place.

Cross-examined by Mr. BARTLEY DENNIS: If the lighting and the trams are about the same in the Durham case as in the Middlesex, but the power to be taken in the Durham case is more than twice that in Middlesex, the load factor in Durham must be higher than in Middlesex?—We have not taken that basis. We have taken the load factor for light as better in Middlesex than in Durham.

The three factors coal, load factor, and quantity, are the ruling factors in the cheapness of the price at which you can sell—that being so, is it not the fact that all three are more favourable in the case of Durham than in Middlesex?—We do not know what they will be yet. We know that coal is more favourable in Durham.

Witness was briefly cross-examined on behalf of the various other local authorities, and the Committee then adjourned until Tuesday, June 19.

CHRISTCHURCH, BOURNEMOUTH, AND WINTON TRAMWAYS BILL.

On Friday last the Select Committee of the House of Commons, presided over by Mr. W. H. Holland, took the Christchurch, Bournemouth, and Winton Tramways Bill and the Bournemouth Corporation Tramways Provisional Order. The promoters of the first-named bill were the Poole and District Electric Traction Co.

Mr. BALFOUR BROWNE, Q.C., for the promoting company, said the bill was one to authorise the Poole and District Electric Traction Co. to construct tramways from the middle of Christchurch into Bournemouth, to be worked by electricity. There were two bills before the Committee, the one he was opening and one promoted by means of a provisional order by the Corporation of Bournemouth, who were proposing to construct lines in Bournemouth running partly over the same route as that proposed by the company, but with ramifications to streets which the company did not proposed to touch. A light railway was already authorised and in course of construction by the company promoting the present Bill, which would connect Poole with the County Gate at Bournemouth, and this line would be very important. Only the Bournemouth portion of the present scheme was opposed. On former occasions attempts had been made to obtain power to construct lines in Bournemouth, but the Corporation opposed on the ground that the introduction of lines along any of the roads of the town would drive away the wealthier class of visitors, who brought with them their own carriages and horses, and upon whom the prosperity of the town in the main depended; and the schemes were rejected. But last autumn when the promoters wrote to the Bournemouth Corporation giving notice of their intention to apply for power to run tramways into Bournemouth, the Corporation, immediately they received the letter, and forgetting all they had said before, promoted a scheme of tramways on their own behalf. Counsel thought in these circumstances the company had been very badly treated. He would not oppose the Corporation bill for the making of the trams, but he asked the Committee to say that if the Corporation scheme were sanctioned the company should have running powers over the Corporation line, so that people could travel from Christchurch to Bournemouth, and then on without change to Poole on the other side of the town; and thus avoid, as might be possible if the company did not possess these running powers, having to change on reaching Bournemouth, enter a Corporation car, change again on reaching the other side of Bournemouth, and proceed thence in a car of the company to Poole. If these running powers were granted the company would give the Corporation running powers over the company's lines. It was absolutely essential that there should be through communication. The only question really between the Corporation and the company was as to who should make the line on the road in the borough in regard to which both sought powers.

Mr. MARSHALL, ex-mayor of Christchurch, said the district through which the trams would run to Bournemouth was rapidly developing, and the trams would materially assist that development. Local feeling was strongly in favour of the company's scheme. In the event of the Corporation being allowed to construct the tramways in Bournemouth the company should have power to run over those lines, and should either party be unreasonable as to terms, there should be power to call in a third party to decide between them.

Mr. PAGE, Q.C., for Bournemouth Corporation, said he admitted the importance in the public interest of through communication, and he should not question the engineering or financial aspects of the scheme of the company. He could not agree, however, that in the event of the company and Corporation differing as to the means by which the through communication should be established a third party should be called in.

Mr. TUCKER, another ex-Mayor of Christchurch, said local opinion was strongly favourable to the establishment of an electric tramway between Christchurch and Poole, and to a through system—not one which should be dislocated at the borough boundaries.

The CHAIRMAN said the Committee were convinced of the desirability of there being a through service.

Mr. W. E. BURT, clerk of the Pokesdown District Council supported the company's bill.

This closed the case for the bill.

Mr. PAGE, Q.C., said if their bill were passed the Corporation would honestly carry out what they proposed. The only question was who should make the tramway in the borough, and he contended that the Corporation were the proper body, as was suggested in the Tramways Act of 1870. The Corporation objected to the compulsory running powers sought by the company with regard to the Corporation lines; it was not in accordance with the practice of Parliament to give such powers.

Mr. WEBBER, mayor of Bournemouth, said he saw no reason why a portion of the system should be severed and handed over to a company. As to running powers the Corporation and the company should be free to make their own bargain. He thought they could agree, and he objected to a third party, even the Board of Trade, being called in to decide between them in case of difference.

Other evidence having been given for the Corporation,

Mr. MOON, for the company, suggested that, having regard to the past history of the Corporation, and the strongly-expressed desires of the inhabitants, it would be well that there should be some security for the construction of the line for through communication. If the Corporation did not construct the tramway between the borough boundary and the centre of the town within two years, the company should have the power. Through communication was the essense of the scheme, and it ought not to be left to the Corporation to determine the terms upon which the company should use the line in the borough. The company should be given compulsory running powers, or else the Board of Trade should appoint an arbitrator to decide the terms upon which the company should be allowed to use the Corporation line. The company were willing to give the Corporation running powers over the company's line to Christchurch and Poole.

The CHAIRMAN asked Mr. Page whether he would agree to the insertion of a clause providing that if the Corporation did not construct this particular line within two years, the company should have power to do it.

Mr. PAGE said he would not object to that clause provided compulsory running powers were not granted.

Eventually the Committee passed the preamble of both measures, inserting the clause referred to, and granting running powers to the company under the terms of the Tramways Act of 1870, and reciprocal running powers to the Corporation with regard to the company's lines.

The bill was then ordered to be reported to the House.

THE ELECTRIC POWER BILLS.

The Special Committee of the House of Commons on Electric Power Bills took further evidence with reference to the Lancashire Electric Power Co.'s measure on Friday last. Sir J. Kitson again presided.

Mr. W. P. J. FAWCUS supported Mr. Gripper's evidence, given in our last issue, as to the cost of carrying out the scheme and the price at which it was hoped to supply electric power. He said the promoters expected that they would have to meet an enormous demand in the Manchester district and elsewhere. The duty of laying the mains ought, he thought, to be in the hands of the company, and not in those of the local authorities.

Prof. S. P. THOMPSON spoke of the advantages of supplying very large areas, and thereby reducing the price of electric energy to the consumer. He said that there were cases abroad in which electric mains extended over much greater distances than were proposed to be covered by the Lancashire Co.'s mains. It had been proved that a power of 100 volts could be carried 100 miles. He declined to assent to a suggestion which was made to him in cross-examination, that the cost of producing power by means of water, as in Italy and the United States, was lower than that of producing it by means of coal, and said that, though nothing had to be paid for the water, enormous sums had to be expended on engineering and hydraulic apparatus. In answer to a remark of a member of the Committee, witness said that the loss of power due to the transmission of electricity for a certain distance was the same in the case of overhead as in that of underground cables.

Mr. J. S. RAWORTH said the promoters of the bill had based their estimates on the requirements of the Board of Trade, and if the Board allowed the use of larger cables than those at present authorised a saving would be effected by the company. Such a saving might run into hundreds of thousands of pounds. He regarded the scheme as thoroughly feasible, and as one that could be worked to the financial advantage of the company.

Mr. G. CALDWELL, mining engineer, and one of the promoters of the bill, said that the collieries in the Ince and Wigan districts with which he was associated would be glad to see the scheme passed.

This closed the promoters' case, and the opposition of 15 district councils, represented by Mr. Wedderburn, Q.C., and Mr. Moon, was then proceeded with.

Mr. WEDDERBURN declared that the bill was an experiment that would result in failure, and hinder the natural development of electricity supply. As the roads were to be interfered with, he urged that the local authorities should have the power of supervising the laying of the cables.

Mr. ASPINALL, clerk of the District Council of Abram, gave evidence that representatives of all the collieries in the district were on the Council, which had petitioned against the measure.

Mr. ROBERT HAMMOND said that in the past provisional orders and licences had been granted in a larger number of cases to local authorities than to companies. The total capital invested under the Electric Lighting Act was about £20,000,000, of which £12,000,000 had been invested by local authorities. In Manchester the Corporation had lately extended greatly their lines of outlet, but the cost of the works had not gone down as in some places by an aggregation of outlet. While he should be delighted to see the whole country covered with power distributing undertakings, he considered that the *quid pro quo* offered by this company to the local authorities was by no means tempting. What was offered was not as good a condition of things as the local authorities could create for themselves.

The Committee adjourned till June 18th.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. WEYMOUTH. Price 7s. 6d. post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By GILBERT S. RAM. Price 7s. 6d., post free.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. GEIPEL and H. M. KILGOUR. Price 7s. 6d. net, post free 7s. 9d., abroad 8s.; large-paper edition, 12s. 6d., post free. New edition in the press.

"THE ELECTRICIAN" PRIMERS. In Two Vols. Paper covers, 2s., post free 2s. 2d. each; strong cloth 2s. 6d., post free 2s. 9d. each. Single Primers 2d., post free 2½d.

WIRELESS TELEGRAPHY: SIGNALLING ACROSS SPACE WITHOUT WIRES BY ELECTRIC WAVES. By Dr. O. J. LODGE. New Edition. Price 5s. net.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING, ELECTRIC TRACTION, TELEGRAPHS, TELEPHONES, &c. A. C. CURTIS-HAYWARD, B.A. To January, 1900. Price 3s. 6d., post free.

CARBON MAKING FOR ALL ELECTRICAL PURPOSES. By FRANCIS JEHL. Price 10s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d., post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 3s. 6d., post free.

FULL CATALOGUE POST FREE ON APPLICATION.

"ELECTRICIAN" SERIES FORTHCOMING BOOKS.

THE ELECTRIC ARC.—By Mrs. AYRTON. This work is in the press, and will contain an historical sketch of the early experiments on the electric arc, as well as the important results of recent research.

PRIMARY BATTERIES.—A work on this subject will shortly be published bringing the theory and practice of the Primary Battery up to date. The book will be fully illustrated.

SECONDARY BATTERIES.—By E. J. WADE. Fully illustrated. The Author in this work will deal briefly with the theory and fully with the chemistry, design, construction and manufacture of secondary batteries or accumulators.

"THE ELECTRICIAN" WIREMAN'S POCKET-BOOK.—Edited by F. C. RAPHAEL. "The Electrician" Company will shortly publish a valuable pocket-book for the use of those engaged in wiring work, both external and internal.

THE TELEPHONE.—By DAVE SINCLAIR and F. C. RAPHAEL.

SPECIAL NOTICE.

NOW READY.—Vol. XLIV. of "THE ELECTRICIAN" (950 pages), bound in strong cloth. Price 17s. 6d., post free 18s. 6d. Also ready, Cases for binding. Price 2s., by post 2s. 3d.

A complete set of "THE ELECTRICIAN" (1878-1900) can now be supplied. These sets are very scarce, and early application should be made.

THE THOMSON METER CASE.

FOR some reason not precisely defined, disputes as to priority of invention always arouse interest in a large number of people not directly, and sometimes not even indirectly, concerned with the matter. Whether the issue be the enunciation of a new physical theory or principle, the new application of a scientific fact to a practical purpose, with a prospect of commercial importance, or whether it be an industrial matter pure and simple, each side has its partisans, and it is rare that the controversy ends by the mere statements of the claims of the inventors, or even that its discussion is confined within the four walls of a court of law. This being the general rule, it is no wonder that the action of CHAMBERLAIN and HOOKHAM *v.* THE BRADFORD CORPORATION, of which we publish the judgment in this week's issue, should have given rise to much comment, for although it may nominally concern only one firm of meter manufacturers and one local authority supplying electrical energy, actually if the decision had been in favour of the plaintiffs a large number of undertakers of electrical supply by continuous currents would have been affected; and, besides the maker of the meter alleged to be infringing, at least one other prospective meter maker might have had his ardour damped. The defendants having won the action, the position is practically "As you were," except perhaps that the importance of the Hookham patent has been considerably lessened, and that it appears no longer to be the master patent some may have thought it after the decision in the Perry meter case (CHAMBERLAIN and HOOKHAM *v.* JOHNSON and PHILLIPS) three years ago.

The action was brought against the Bradford Corporation as users of the Thomson meter, which, it was alleged, infringed the meter or meters described in Hookham's specification, No. 4,225, of 1887. The actual Hookham and Thomson meters, as built at present, are both motor meters with Foucault brakes—and there the resemblance apparently ends. While on the one hand the Hookham instrument measures ampere-hours, and its motor has a permanent magnet field, the main current being led through the armature by means of mercury contacts to the commutator, the Thomson meter, on the other hand, is an energy meter in which the main current passes through the field and a shunt current is led to the armature through silver brushes resting against an ordinary divided commutator. However, the question was not between the two meters, but whether the Thomson meter,

Digitized by Google

as used at Bradford, could be deemed to have been made in accordance with the Hookham specification. The qualification, "as used at Bradford," is added advisedly, for the plaintiffs' advisers evidently saw that the meter *per se* was no infringement. Hookham's specification was for a quantity meter and a quantity meter only, and the Thomson meter is essentially an energy meter. But, said the plaintiffs, the Bradford Corporation is employing their meters on constant pressure mains, and we give the Corporation engineers the credit of keeping the pressure at their consumers' terminals absolutely constant, and then their energy meter does no more than measure ampere-hours just as our does. The judge did not take this view. He held that the fact that the defendants at Bradford had hitherto supplied electricity at a constant uniform pressure, did not render it unnecessary to have a meter capable of measuring whether they do or do not keep up such uniformity; to say that the defendants had not proved that they had deviated in the past from the Board of Trade regulations was an attempt "to turn their virtue against them in a manner quite unwarrantable." No doubt several of the principles underlying the Thomson meter are enunciated in Hookham's specification. For instance, it explains that either a permanent magnet field or an electromagnet field can be employed, and that the motor can be constructed with the main current passing through the field and the shunt current through the armature or vice versâ. But it has now been abundantly proved, if it had not previously been proved in the Hookham-Perry case, that the principles underlying the motor meter and Foucault brake had been set forth before, and were therefore "common knowledge" at the time of the specification. Ayrton and Perry's historical specification describing both their "erg-meter" (the precursor of the Aron meter) and the motor meter with disc brake—without, however, sufficient detail in the latter case to enable an efficient meter to be constructed—was again brought forward in evidence; but to this was added an article by Marcel Deprez in the *Lumière Electrique*, of January, 1884, describing the Siemens' energy measurer, which was a motor meter with a paddle brake, and pointing out how this instrument might be improved by adapting to it a magnet and disc brake which he had previously employed in an electro-magnetic speed indicator, and also an article by Uppenborn in the *Centralblatt für Electrotechnik* repeating, and to some extent enlarging on M. Deprez's conclusions. Incidentally it may be remarked that this case emphasises more than ever the value of technical journals and the importance of studying them. Mr. Ferranti, in his evidence, stated that, had he read M. Deprez's article at the time, he could have constructed a properly working motor meter in accordance with the instructions, and a motor meter resembling the Thomson meter. Yet, until over three years later, when Mr. Hookham succeeded with the first pattern of his meter, we believe that no really practically working meter of this type had been put on the market, although a demand for electricity meters existed. To return to the present lawsuit, however. The principle of the motor meter with a Foucault brake being "common knowledge" previous to the date of Hookham's specification, it only remained to show that Hookham and Thomson had employed different means of applying this commonly-known principle practically. This the judge stated had been done to his satisfaction. From his judgment it will be seen that he had attained a thorough grasp of the case in spite of all its intricate technicalities, and the same can be said of all the counsel employed. Yet considerable time has always to be spent in all such cases in educating the legal fraternity up to the required standard, and it is doubtful whether it would not have been more useful to appoint a committee to consider the question of reform in the methods of patent litigation rather than one to consider the few points in patent law included in the reference to Sir Edward Fry's committee—the text of which reference will be found in another column of this issue. It is surely of more importance that the means of testing the validity of patents, and of suing with regard to infringements should be cheapened, than that help should be afforded to the slovenly inventor who is too lazy or not sufficiently educated to ascertain for himself whether his invention has been anticipated.

CONTEMPORARY ELECTRICAL SCIENCE.

[Compiled by E. E. Fournier d'Albe.]

Electric Dispersion of Ice.—By means of the method used for comparing the rates of propagation of electric waves through bitumen with and without wires, C. Gutton has determined the dielectric constant and electromagnetic dispersion of ice. The refractive index was found to be 1·76, which would give a dielectric constant of 3·1. The ice was perfectly limpid and dry, and was examined at a temperature a little below zero. It did not perceptibly absorb the electric waves. The value found for the dielectric constant is much higher than that obtained by Blondlot by a different method, and the author therefore suspected that ice would show considerable dispersion for different wave-lengths. The original method not being available for great wave-lengths, he used that devised by Blondlot, in which the wave-length proper to the same resonator is measured first in air and then in the medium under investigation. The refractive indices thus obtained cover wave-lengths ranging from 14 to 2,000 cm. For the smallest wave-length the refractive index is 1·76, as already stated. This becomes 1·73 for a wave-length of 25cm., and so it goes on decreasing with increasing wave-lengths until it reaches 1·50 at a wave-length of 2,088cm. This gives a dielectric constant of 2·25, which is not far from Blondlot's value of 2·0 found in still greater wave-lengths. Within the region investigated the dispersion of ice is normal. But it yet remains to connect it with the optical dispersion, which is characterised by even smaller refractive indices.

[C. Gutton, *Comptes Rendus*, April 23, 1900.]

Armoured Galvanometers.—The protection of magnetic observatories, necessitated by the development of electric traction, involves the absence of any magnetic other than that of the earth from the observatory grounds. Protection of the instruments from all external action would eliminate the very field it is desired to study. The same difficulty does not occur in the protection of galvanometers, where an artificial field is created and measured, and the total absence of any other field is the best possible condition of working. The protection of galvanometers by suitable "armour" is therefore a problem well within the sphere of practical electricity. Such armoured galvanometers have been constructed in various patterns by du Bois and Rubens. Theoretically, the best form of magnetic shielding is by a spherical shield, but there appear to be technical difficulties in the way of providing a suitable material for such a shield. The authors have, however, at length overcome this difficulty by the preparation of a special cast steel capable of taking a thin spherical surface. This cast steel, which is prepared by a process the details of which have not as yet been published, has a high initial permeability and very small coercive force. It is not only used for the two hemispheres of the outer armour, but also for a special armouring of the coils themselves. The planes dividing the outer and the inner hemispheres respectively, make an angle of 90deg. between them, and the combined system gives a production amounting to a hundredfold reduction of the disturbance. Usually a cylindrical outside armour is added, which makes the protection a thousandfold one. Quartz fibres are used for suspension.

Effect of Heat on Vacuum Discharges.—The distribution of the waste of energy in vacuum tubes has been measured by determining the quantities of heat given out at different points, or by studying the potential gradient. The dissipation of energy is, of course, greatest where the gradient is steepest, and so both methods yield substantially the same data. But the measurements, with the exception of those of Pandolfi, have hitherto been confined to ordinary temperatures, and Pandolfi confined himself to finding the total difference of potential rather than the gradient in various parts of the tube. G. C. Schmidt has, therefore, examined the potential gradient at different temperatures, ranging from 15°C. to 300°C., paying special attention to the differences in behaviour between the positive light column and the dark cathode space, which, as we know from the researches of Wiedemann and Wehnelt, acts virtually as a dielectric, freely transmitting electric oscillations, and breaking down under heavy dielectric stress much as would a layer of petroleum. The method used was that of probes, platinum electrodes being fused into the gas at various intervals. The most striking effect of heating was that the continuous positive light was split up into stratifications, which on further heating were gradually displaced towards the cathode, so that eventually a dark discharge was produced. At the same time, the potential gradient at the cathode was found to be unaffected by a change of temperature, until a point was reached at which the cathode was entirely covered with glow light, or heated to a white heat. After that the gradient would become steeper. In every case, when the discharge became non-luminous it was found that the gradient was steepest at the anode, and that its steepness was in fact proportional to the distance from the cathode. This relation is very suggestive from the point of view of the ionic theory. [G. C. Schmidt, *Ann. der Phys.*, No. 4, 1900.]

Dielectric Hysteresis and Viscosity.—Since the work of Arno, it is well-known that a dielectric placed in an alternating electrostatic field gets heated, and that the heating is proportional to some power of the E.M.F. Similarly, Janet has proved that with increasing potentials the charge of a condenser is feebler than it is when the potentials are decreasing. This lag is due either to viscosity or to hysteresis. Arno supports the latter alternative. In that case the dissipation of energy should be independent of the rate at which a cycle is completed. The experiments of F. Beaulard, however, point to the opposite conclusion. He charged a condenser to the same potential during various time intervals ranging from 4 seconds to 600 seconds, and compared the charges by sending them through a ballistic galvanometer. He found that the loss of energy in the condenser decreased as the time increased, and that if the process of charging the condenser was extended over an interval of 15 minutes the loss was nil. He, therefore, concludes that the effect is due to viscosity rather than hysteresis.

[F. Beaulard, *Comptes Rendus*, April 30, 1900.]

International Observation of Magnetic Storms.—The characteristics of "magnetic storms" point towards local processes as their proximate causes, which, though producing simultaneous disturbances over the entire earth, confine their strong influence to a limited area. Since these local processes are probably electric currents in the higher strata of the atmosphere or in the earth's crust, they may be of the nature of wandering current vortices. Whether these are situated in the atmosphere and the terrestrial phenomena are effects of induction, can only be determined by simultaneous observations extending over thousands of miles. The only such area at present adequately supplied with magnetic observatories for such a purpose is Europe and even there the number of Northern observatories, which are specially important for this object, is somewhat small. A. Schmidt gives some general principles which should govern the action of an international combination of observatories organised for this study. Absolute measurements are not indispensable. It suffices to have the values of the elements compared with those laid down on the existing charts. The apparatus of the different stations should be at least approximately of the same sensitiveness, but that sensitiveness need not be very high, as it is a question of comparing considerable variations. In the declination, for instance, accuracy up to one minute of arc suffices. The needles should be strongly damped. The epochs should not be too numerous, so as to avoid overworking the staff. The observations should be handed in fully reduced, and the prompt publication of the results should be ensured.

[A. Schmidt, *Terr. Magnetism*, March, 1900.]

CORRESPONDENCE.

THE ABSORPTION OF ELECTRIC WAVES.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: Having recently constructed an apparatus for the production and detection of electric waves having a wave-length of only a few inches, I have been interested to find how easy it is, when certain precautions are taken, to exhibit experimentally with this apparatus, of quite moderate dimensions, the chief properties of electric waves and the electro-optic qualities of bodies. With these appliances, which I shall describe later on, the transparency and refractive power of insulators, opacity and reflective power of conductors, and polarisation effects are most readily and strikingly shown. The apparatus is especially adapted for testing qualitatively the absorptive powers of various substances for electric waves. It is accordingly found that paraffin oil, benzol, turpentine, and all insulating liquids of low dielectric constant prove to be exceeding transparent, but water, and many liquids of high dielectric constant, are very absorptive. The waves I have been employing (of about 8in. wave length) pass easily through a wood board an inch thick, a dozen sheets of window glass, a dozen thicknesses of dry washleather, a thick slab of ebonite, but are stopped almost completely by a couple of wet cloths, or $\frac{1}{8}$in. thickness of water, and by any substance which is very moist. Ice on the other hand, if *dry* on the surface, is transparent to them. Constructing a large ice prism I have readily refracted these rays by it, and measured approximately the refractive index of ice for them. It proves to be a number near to 1·7 or 1·8. The human hand and body are very opaque to these particular electric rays. I have also found they are absorbed by some vapours. The red nitrous fumes produced by the action of nitric acid on copper appears to absorb them to some extent even if only a few inches in depth, although they will pass easily through a slab of ice some 4in. in thickness. They are easily reflected from a surface of glass, and a very striking experiment may be shown by reflecting them at 45deg. from the palm of the hand. By splitting an electric beam into two parts, and sending the two portions along two zinc tubes, which can be varied in length, the interference of two electric rays is most easily shown, and the wave length measured. Any substance which has conductivity or large dielectric constant in one direction only is very absorptive of these rays when that direction is placed parallel to the electric force of the ray falling upon it. Thus a paper of pins stops the rays when the pins are held with their length parallel to the direction of the electric force, but not when they are held normal to it. The strongly absorptive character of distilled water or alcohol shows that in these cases it is not so much conductivity as large dielectric constant which seems a determining factor. As the experiments have not proceeded very far it is necessary to refrain from generalisation, but it appears very much as if all substances which contain in their chemical molecule either hydroxyl (HO) or nitryl (NO_2) are in the liquid, and perhaps in the gaseous, form very opaque to electric radiation, the wave length of which is not more than a few inches.

In the case of water it would seem that the absorption band known to exist in the ultra red water spectrum extends as far as wave lengths, 200,000 or 300,000 times as long. The electric refractive index I have found for ice is in very fair agreement with the square root of the dielectric constant for high frequency reversals of electric force.—Yours, &c.

LONG DISTANCE TRANSMISSION OF POWER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your leading article on May 18, you refer to my remarks on the recent Paper of Prof. Forbes. I would explain that I thought the Paper a practical joke. I could not praise the Paper, so the author became angry, and suggested many times that when I read his Paper more carefully I might change my opinions. I was indeed a little disconcerted, nevertheless I beg to ask for a careful consideration of what I said, as I think that it was, and is, and will be, of great importance. Furthermore, I said that I had not had time to examine the figures of the Paper, and I hereby declare that I had no intention of condemning those figures until I was bullied into doing so. I had no doubt whatever about the wrongness of his figures, but as he had described six quite different systems on which he was in the habit of making calculations, as I suspected that they were all wrong systems, I knew that if I chose any one of these systems and proved his numbers to be wrong, he had five lines of retreat.

Allow me now to show you how the thing appeared to me at the time. In our old 1886 Paper, so reviled as nonsensical at the time by Prof. Forbes and commended by him now, we proved that the efficiency in an ordinary transmission system (no boosters) could not be less than 50 per cent. What we meant will become quite clear from the following arithmetical example:—Take any case one pleases of power transmission where the efficiency seems as if it might be less than 50 per cent. For example: Generator voltage 1,000 volts, current 200 amperes, resistance between generator and motor 3 ohms. The voltage at motor is 400 volts. The power delivered is 80 kw. The efficiency of transmission 40 per cent. Now notice that, if such a case could by accident exist, it could only continue to exist by some careful and curious way of governing the speed of the motor. If the motor is allowed to run up in speed so that it may work at 600 volts, it will receive 133⅓ amperes through the same resistance, and therefore the same power, 80 kw., will be delivered, the efficiency of transmission now being 60 per cent. It is in this sense that I affirmed the non-existence of any case of transmission where there is an efficiency of less than 50 per cent.

Now, surely I may take it that this is clear even to the man most scornful of science, and especially of elementary algebra.

To apply my result in the present case: Consider in Table II. his total efficiency 0·12. In whatever way he worked he would certainly get his best result by having the same efficiency $\sqrt{0{\cdot}12}$, or 0·3464, in each of the two sections. If he did not have them equal, one would be less than this. This statement applies to any of his six systems of calculating. But I have proved that if he, using only arithmetic and domestic mathematics, gets an efficiency 0·3464 or less, for a section, then I know that with the very same conductor and same generator voltage I can deliver the same power with an efficiency of 0·6536 or more, through that section. This was my rough and ready way of looking at the matter at the time, but I did not like to put it forward, for it certainly understates my case. Nevertheless it is useful as giving condemnation of the published figures.

The following result is more exact: Prof. Forbes puts it that, with a certain conductor and given generator voltage, to deliver 1 H.P. at the distance of 100 miles, using boosters, it is necessary to waste 7⅓ H.P. in overcoming ohmic resistance. I affirm that, with the same generator voltage, and same conductor, he can deliver 1 H.P. at the same place at the same voltage, his total ohmic loss being only 0·28 H.P., and he need not use anything like such large boosters. I also say that, if he starts working in his own uneconomical way, taking no precautions to maintain this want of economy, his boosters will quickly alter things so that the transmission of energy will proceed, not in his way, but in my way.

I was very much understating my case when I said that in no section of a boosted system can the efficiency be less than 50 per cent. In fact, there can be no total efficiency in the system of Table II. less than 33 per cent., and no efficiency in either of the two sections of that system less than 57⅓ per cent. Also, there can be no total efficiency in the system of Table III. less than 25 per cent., and no efficiency in any section of such a system less than 63 per cent. Thus, for example, in Table III., where he gives 11 per cent. I find that the total efficiency need not be less than 44, and where he gives 13 per cent. the efficiency need not be less than 40.

The proof of these and no end of other interesting statements is quite easy, but I must confess that it needs elementary algebra, so that it is quite hopeless to convince Mr. Swinburne. I had not known that he was interested in power transmission, else by many concrete examples I might have endeavoured to give to him the information which my simple formula expresses.

You will recollect that I called attention to the possibly great extra cost of the power transformed by the boosters, neglected by Prof. Forbes. In his Table II. (his line of two sections) when his efficiency is 0·12, his boosters generate 2·5 H.P. for every horse-power delivered; even by my figures the boosters generate 0·5 H.P. for every horse-power delivered. I do not see why Prof. Forbes should have been so angry when I ventured to suggest that there was really no practical need for boosters to keep up the voltage.

I must say that I am still of that opinion and I think that Prof. Elihu Thomson, who patented this booster system of Prof. Forbes, many years ago, is of the same opinion.—

Yours, &c., JOHN PEERY.

May 17, 1900.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In reference to Professor Elihu Thomson's well-known use of boosters in power transmission, may I put before your readers the result of a calculation. In deference to the wishes of those who want to know facts and do not care for reasons, I forbear to give the simple algebra on which the calculation is based, but any of the younger electrical engineers can get it out for himself. I have assumed the same current density throughout. It is easy to extend the reasoning so as to have less current density at greater distances from the generator. I take the case of a generator at $v_1 = 10{,}000$ volts; I receive $P_0 = 5{,}000$ kw. at the voltage v_0 at the distance of $\frac{1}{2}n$ miles or 100 miles from the generator. I assume the costs of power and of copper to be such that by the simple Kelvin law there ought to be 500 amperes per sq. in. in the copper (or $t = 20$ in the Ayrton-Perry Paper of 1886). Practically this means that the cost per annum of one ton of copper is 1 kw. at the generator. All values are reckoned in watts. In calculating column 5, I assume that the transformation of power by a booster costs three times as much as the original generation of the power; it is easy to change the numbers if this ratio is objected to.

Instead of making many tables—one for a few boosters, another and others for more and more, taking many cases—I have assumed that the current is continually boosted—an infinite number of infinitely small boosters, because the results are much the same and the algebraic expressions are simpler to think about.

I. $v_1 - v_0$ is the total drop of voltage on the line, and I use the letter m for $\frac{v_1}{v_0}$. Let there be everywhere A amperes per square inch in the copper. Let n miles be the whole length of the conductor. Use the letter μ for

$$m^{\frac{m}{m-1}\cdot\frac{0{\cdot}04A}{v_1}} - 1,$$

then ohmic loss $= P_0\mu$ kilowatts.

Loss because of cost, &c., of copper $= P\left(\frac{t}{0{\cdot}04A}\right)\mu$ kilowatts, where $t = 20$.

Energy transformed by the boosters $= P_0\mu\left(1 - \frac{v_1 - v_0}{0{\cdot}04An}\right)$.

II. When v_0 is equal to v_1 and the boosters maintain a constant potential,

Let $\gamma = \frac{0{\cdot}04A}{v_1}n$; then, if C_0 is the received current of 500 amperes, ohmic loss $= C_0 v_1 (\epsilon^\gamma - 1)$ watts.

Loss because of cost, &c., of copper $= C_0 v_1 (\epsilon^\gamma - 1)\left(\frac{t}{0{\cdot}04A}\right)^2$ watts.

Energy transformed by booster $= C_0 v_1 (\epsilon^\gamma - 1)$ watts.

Delivering 5,000 kilowatts at a distance of 100 miles by direct current from a generator at 10,000 volts :—

—	Amperes per square inch.	Percentage drop of potential in 100 miles.	Kilowatts ohmic loss.	Kw. loss because of cost of copper.	Three times the power tr'nsformed by boosters.	Total loss in kw. ohmic + copper + boosters.	Total tons of copper.	Power delivered / Power at generator
Simple Kelvin rule...	500	0·20	1,250	1,250	0	2,500	1,203	0·8
Ayrton-Perry rule...	409	4 16	979	1,461	0	2,440	1,496	0·836
Ditto.	205	8·19	446	2,662	0	3,108	2,561	0·918
Boosters	300	8·19	665	1,848	633	3,146	1,747	0·885
	400	8·19	910	1,421	1,332	3,663	1,310	0·848
	500	8·19	1,234	1,234	2,186	4,654	1,189	0·802
	100	0	205	5,125	615	5,945	4,930	0·962
	200	0	415	2,594	1,245	4,254	2,494	0·926
	250	0	525	2,100	1,575	4,200	2,022	0·905
	300	0	635	1,764	1,905	4,304	1,697	0·893
	400	0	880	1,374	2,640	4,894	1,322	0·850
	500	0	1,110	1,110	3,330	5,550	1,061	0·820
	600	0	1,360	945	4,080	6,385	909	0·786
	800	0	1,870	732	5,610	8,212	709	0·729
	1,000	0	2,455	614	7,365	10,434	591	0·671
	2,000	0	6,125	383	18,375	24,883	368	0·450

As I take it, the most economical figures here for each of these drops of potential are :—

—	Amperes per square inch.	Total loss on line.	Percentage drop of potential.	Tons of copper.
A.-P. rule (no boosters)	409	2,440	16·4	1,496
Ditto.	205	3,108	8·19	2,561
Boosters	250	4,200	0	2,022

If we do not mind having a drop of 16·4 per cent., it is evident that the old Ayrton-Perry rule without boosters is the best. I take this as my standard. If we may have 8·19 per cent. drop, still the Ayrton-Perry rule without boosters is the best: there is a total loss of 27 per cent. more than in the standard case. If, however, we may have no drop of potential, then the use of boosters with 250 amperes per square inch in the conductor is the best, but we have a total loss of 72 per cent. more than in the standard case.

I said in a recent discussion that I know of no reasons why, with the above voltage and for such a distance, it should be at all necessary to use boosters, for a drop of 8 per cent. is not important and the saving in not using boosters is very great. When no boosters are used it is easy to show that the most economical result as to ohmic loss and price of copper is obtained with a conductor of the same section throughout.

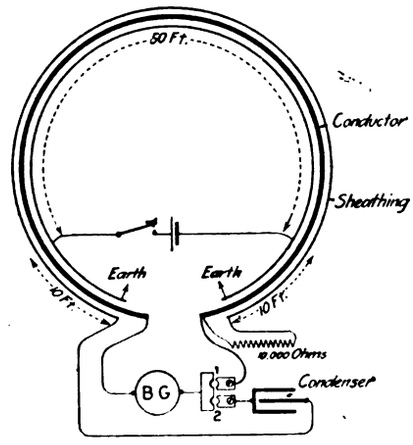
If the price of copper is so great that the simple Kelvin rule would give 1,000 amperes per square inch, it is necessary to divide all the numbers of the column headed "Loss because of cost of copper" by 4.—Yours, &c,

May 17, 1900. JOHN PERRY.

ELECTRIC TRACTION CURRENTS AND SUBMARINE CABLE WORKING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: It is only recently that I have been able to act on Mr. McWhirter's suggestion (see his letter in *The Electrician*, Vol. XLIV., p. 868), and to repeat the experiment recorded in the discussion on Prof. Jamieson's Paper on this subject, and illustrated by his Fig. 12. This figure, according to the advocates of the electromagnetic induction theory, correctly represents the actual working conditions at Cape Town. The figure which I append is practically identical with Fig. 12 in the discussion when the key is placed in the hole 2 of the two-way plug. But I have introduced an additional connection by means of which, when the plug is in hole 1, the galvanometer is simply connected across the two ends of the core, and thus subject to electromagnetic induction pure and simple. In order to make the object of this arrangement quite clear, I cannot do better than quote the following two sentences from the discussion :—"Mr. Sayers said that . . . these effects were not produced from induction solely, for he thought that the battery current split at the point of attachment to the sheathing. *If it did, the portion of the current which came from this attachment along the sheathing to the telephone was opposed to the induced current from the central core, and so it was in the case of the Cape cable*" (the italics are mine). From this it follows that a simple determination of the *direction* of the disturbing current will finally settle the point at issue. For this reason, I substituted a Crompton "Midget" ballistic galvanometer for the telephone, which cannot be used for giving the direction of a current. When the plug was in hole 1, so that the most favourable conditions for electromagnetic induction were produced, the galvanometer gave a throw of 15 scale divisions to the *right* when the battery circuit was *made*. On transferring the plug to hole 2 (corresponding to actual conditions at Cape Town), a throw of 11



scale divisions to the *left* was obtained when the battery circuit was *made*, the capacity of the condenser being 1 microfarad. With 4 microfarads 42 scale divisions were obtained.

The results hardly require much comment, and clearly show how utterly insignificant the effects of electromagnetic induction are in the case considered.—Yours, &c.,

Liverpool, May 26, 1900. ALFRED HAY.

GUARINI'S WIRELESS TELEGRAPH REPEATER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR,—Reading, rather late, the issue of April 20th of your esteemed journal, to which I have subscribed for a long time, I find on p. 932 a review of a pamphlet by M. Guarini on the wireless transmission of electricity, and in it an allusion to the use which the author has made of my name. I have the honour to send you herewith the *Bulletin* of the Société Belge d'Electriciens, reproducing my lecture of November, 1899, entitled "Some Advances in Wireless Telegraphy." In it a brief description of the repeater devised by M. Guarini (a kind of telegraphic relay) follows a summary of the principles and the most remarkable results of wireless telegraphy. Desirous of putting my colleagues *au courant* with interesting novelties, and fulfilling, at the same time, a duty of hospitality towards a young foreign inventor, I have not considered myself able, however, to carry further the exposition of his ideas.—Yours,&c.

E. GÉRARD.

Office of the Minister of Railways, Posts, and Telegraphs, Brussels, May 26.

[In the report of the lecture enclosed with his letter M. Gérard explains that, in treating of things in which he is little versed, he does so in order to carry out the recommendation that every member of the Society should relate at its meetings any novelty he has come across, and because the inventor did not know enough French to explain his invention himself. After a brief explanation of the principles of wireless telegraphy and a historical retrospect, he proceeds to describe M. Guarini's apparatus, leaving it to M. Guarini himself, if he desires it, to give an exposition of the complete theory on which the efficiency of the essential parts of the system depends. M. Gérard concludes as follows: "Such [various suggested wireless telegraphic possibilities] are the ideas of M. Guarini, which do not appear to me incapable of realisation by the progress which his invention promises. I conclude here, leaving M. Guarini to explain his theory of metallic screens and curvilineal 'antennæ,' on which depends the action of his successive repeaters. Let us congratulate M. Guarini, and let us congratulate ourselves on being able to count him among our new colleagues."—ED. *E.*]

IMPERIAL TELEGRAPHIC COMMUNICATION.

Before the Foreign and Colonial Section of the Society of Arts, on Monday, Sir E. A. Sassoon, M.P., read a Paper on "Imperial Telegraphic Communication." The Paper traversed practically the same course as that covered by the discussion in the House of Commons (fully reported in our last issue), except that Mr. Hanbury's reply to the attacks of Sir E. A. Sassoon upon the cable companies had tempered the hon. gentleman's remarks, and consequently the Paper fell somewhat flat. The remarks of the President (Sir H. H. Fowler, M.P.), were, however, more to the point. He said: "This question of submarine telegraphy was a very difficult one. In this country the Government never begins anything. It is left to private entetprise and private capital, especially where any risk is involved. Now telegraphic inventions were from the first in private hands and the Government did not favour its development in past times. The telegraph system had been allowed to grow up, and he was quite sure that it could not be disturbed or settled without a great deal of inquiry and consideration, so as to secure what was right both to those who had risked their money in the concern, and the wider public beyond who might have arrived, and he thought would arrive, at the ultimate conclusion that this was not a matter which should be left in private hands. He regarded the submarine cable enterprise from a threefold point of view. It had a commercial aspect, but it was something more than a commercial enterprise. It had a social and personal character. We were seeking to knit all the subjects of the Queen in various parts of Her Majesty's dominions into one undivided empire, feeling the impulse from the centre, and at the same time developing to the fullest extent that local self-government which they had carried out and could carry on with the greatest advantage to themselves and to the Empire at large. Now we wanted to bring our colonial fellow-subjects into the closest possible communication with us day by day. That could not be done unless the means of communication were facilitated to the utmost of our power, and reduced to the lowest possible cost. He maintained that in a great colonial empire like ours it was worth our while paying money not commercially remunerative to secure free cable communication with the various parts of the empire. This was to be regarded as a great national service, irrespective of commercial considerations, which did not enter into our telegraphic system at home, where 10 millions o capital did not yield a shilling interest. Yet no Government would venture to increase the telegraphic rates at home. Then, on every ground it was of supreme importance to the interests of this country that our communications with India of every kind—in the transit of goods and passengers and in the facility and economy of telegraphic messages—should be in daily touch with the mother country. Then there was the military aspect of the question. A great empire like ours, with colonies in every part of the globe, with great possessions in Asia, Africa, America and Australasia, ought to have a communication of its own, under the control of its own Government, independent of all private companies and foreign nations, which would be a powerful element in its equipment for defence against whatever happened. He held that the time had arrived when there should be an inquiry by independent, impartial, competent men into the past history of the case, into the present position of all these cable enterprises, and into the wisest and best course to be adopted for the future. That Committee, while careful of all fair and legitimate interests involved, would point out to Parliament, the Government, and the nation at large whether any, and if any, what changes should be effected in so potent an instrument between the home Government, its Indian Empire, and the Colonial Empire, in which instrument he thought there were at present many weak spots and possible dangers, against which we ought to guard."

Sir PATRICK PLAYFAIR said the unfairness from which India had suffered in the matter of telegraphic rates was perhaps partly due to the reluctance shown by the Government to guarantee any loss of income that might temporarily ensue on the reduction of rates to the extent of 50 per cent. or 75 per cent. of existing rates, the opinion being held, he understood, by some of the officials of the Indian Government that it would be unfair to make the general taxpayer meet any part of a deficit, however temporary, that might follow upon a reduction of charges between England and India, as the benefit would be received by a small section only of the community, and be largely for the benefit of the European as distinguished from the Indian community.

The Hon. GEORGE PEEL said the broad issue which faced them in connection with this question was whether submarine cable enterprise was to be in the hands of private persons, or in those of the State. There would shortly be 190,000 miles of submarine cables laid in the sea, of which 20,000 only were owned by different States, and what was more these 20,000 miles were laid almost entirely in territorial or inland waters. It might, therefore, be said that the whole of the great international traffic of the world was conducted by cables in the hands of private companies. It had been truly said that Governments did not care to embark their capital and credit in these enterprises, and the public functionaries were not the proper persons to be creators of international trade. He (the speaker) would therefore look with a close and careful eye on the proposals made to abandon the experience of the past. He then passed in review various proposals made in the Paper read by Sir E. A. Sassoon and in the statements made in the House of Commons during the recent debate on the question, subjecting many of these statements to severe criticism.

Sir John Leng, M.P., Sir M. M. Bhownaggree, M.P., Mr. R. K. Gray, and Mr. Chas. Bright also took part in the discussion.

At the Royal United Service Institute, London, on Monday, Sir John Colomb, M.P., presided at the reading of a Paper by Lieut. C. W. Bellairs on "The Routes of Submarine Cables." Lieut. Bellairs took as a test case the proposed "all-British" Pacific cable, and contrasted the proposed line with another laid and worked by British capital but touching foreign territory. He said that, so far from finding it a disadvantage to land the cable on territory belonging to a strong neutral Power like the United States, it was a positive gain. The principal objections to the proposed all-British cable were that by international law, as the cable would not touch neutral territory, a belligerent would be at liberty to cut it anywhere along the 8,000 miles, and the landing stations, not being on neutral territory, would have to be protected. The proposed cable entailed a span of 3,560 nautical miles, the longest in the world by over 350 nautical miles. It would mean the loss to Canada, Australasia and our shipping trade of direct communication with Hawaii. The Americans were about to lay a cable from San Francisco to Hawaii, and if we did not connect Australasia with this system others would probably connect New Caledonia. If connected with Hawaii Australasia would obtain a fresh line to the East by the projected American cables to the Philippines. The risk of being cut in time of war would be much greater to an all-British cable than to one following a natural route to friendly neutral territory. The natural route, too, was always the cheaper to lay and maintain, while it opened up the largest market for commerce. In time of war it would be a very easy thing to lay special strategic cables for naval use. For the rest naval requirements were the same as those of commerce—a multiplicity of routes—so that if a cable were lost in one direction the message could be sent by another route.

In the course of the discussion which followed Col. Sir George S. Clarke said the lecturer had fairly pricked the bubble of the all-British cable, which was threatening to extend in a most harmful way. There was something unwholesomely fascinating about the word "strategic." After all, strategy was merely a question of applying common sense, and Lieut. Bellairs had applied common sense and pricked the bubble of an all-British cable. There was no international agreement about the cutting of cables in time of war. The only question was the difficulty of doing so. When it came to war belligerents would do anything they could unless it was a thing likely to shock the world, and the cutting of cables would not shock the world. The most important strategy for the British empire was the strategy of commerce. The cheaper and more certain telegraphic communication was made the better it would be for this country in peace or in war. Our policy should be to discourage monopolies and to encourage cheapness of communication and an increase in the number of lines for purely commercial purposes.

Sir John Colomb in the course of a few concluding remarks, said he held very strongly the conclusions of the lecturer. The commercial argument for all-British cables had proved weak, and therefore the strategic argument was used as a crutch to help up the cause.

PARLIAMENTARY INTELLIGENCE.

GLASGOW DISTRICT TRAMWAYS BILL.

A Select Committee of the House of Lords, under the chairmanship of Lord Herries, considered this bill last week. The promoters seek to incorporate a company to construct electric tramways in and around the burgh of Paisley.

Mr. PEMBROKE STEPHENS, Q.C., for the promoters, explained that the original proposals for the construction of new tramways on the north side of the Clyde had been dropped, but from the termination of the Glasgow Corporation Tramways and Balloch Bridge eight sections of tramways remained. No. 1 started in Johnstone, and connected with existing lines of the Paisley tramways; No. 2 occupied the site of the Paisley tramways; No. 3 was a tramway running out of Paisley and going as far as Abbotsinch on the road to Inchinnan; No. 4 was a tramway running through Paisley, connecting with the Glenfield Scouring Works and the opening to the Braes of Gleniffer; No. 5 was a short line in Renfrew; No. 6 was a continuation of No. 5 running from Renfrew to Paisley, and completing a through route; No. 7 was a line from Renfrew to Govan; Nos. 8 and 9 were small subsidiary lines. The Govan section would be about 2 miles in length. The gauge would be 4ft. 7½in., so that if desired afterwards there would be difficulty in making a physical connection. All the tramways would be worked by electricity, and be constructed on the overhead system. The tramways would have to go over or under bridges crossing lines of railway, but the promoters did not interfere with railway works. Local feeling had been expressed in favour of the proposed lines, and the undertaking came up with the assent and approval of the Town Council of Renfrew, the Police Commissioners of Johnstone, and the County Council of Renfrewshire, and the Upper Ward District Committee of that Council, and with the support and assent of the burgh of Paisley, who had two agreements with the promoters scheduled to the bill. The petitions against the measure were those of Glasgow Corporation, Lanarkshire County Council, Clyde Trustees and the Glasgow and South-Western, the Caledonian, the Glasgow and Paisley Joint Line, the Paisley and Barrhead District, and the Glasgow and Renfrew District Railway Companies. So far as Glasgow was concerned, the opposition was a matter of clauses. The petition of the Clyde Trustees proceeded on the misapprehension that there would be a tramway ferry and an electric cable across the Clyde, which would interfere with the navigation of the river. There would be no such cable, and a ferry had never been thought of. The County Council's opposition was in the nature of a legal objection to the laying of the Govan line. The objection of the railway companies was on the ground of competition.

Mr. WILLIAM BARRINGTON, C.E., the engineer under the bill, said the period for the completion of the whole scheme was five years, but tramway No. 7 would take only seven or eight months to build. It had never been intended to have a tramway ferry across the Clyde. At one

Digitized by Google

time it was in contemplation to put the main electric cable under the Clyde, so as to connect the trams on the north with those on the south side, but that was only to be done if the Clyde Trustees consented, and now that Dumbarton was out of the bill altogether there was no necessity for the cable. There was nothing in the objection that the tramways would interfere with the electrical signalling apparatus on the railway. The bill contained the ordinary parcels clause. It was not intended to carry goods, and the promoters were willing to give a clause prohibiting them doing so. The tramways would not be railways on the public road. The carriages would not be railway carriages. They were departing from the general law allowing the local authority the option to purchase at 21 years, because it was now usual to make a departure from the Tramways Act. He did not know whether it was proposed to supply outsiders with electricity in bulk. The promoters were seeking to reconstruct the Paisley tramways. At present their trams were single lines, and it was proposed to double them throughout. The total estimated cost of the lines proposed was about £180,000.

A mass of local of evidence in favour of the bill was then taken, after which Mr. WM. M. MURPHY, chairman of the Dublin United Tramways Co., and one of the promoters, stated that the Dublin tramways were the largest system of electric tramways in the United Kingdom. They were worked from a single generating station, which was (he asserted) the largest in this country and one of the best equipped in the world. He was a director of tramway undertakings in London, Belfast, Cork, and other places. At present he was engaged in the construction of tramways at Margate, Ramsgate, and Broadstairs. If necessary he would find the whole of the capital without any appeal to public subscriptions, but if the local people wished an opportunity of investing in the undertaking he would give it to them. The circumstances at Cork were not unlike those of Paisley, and the system he had constructed in Cork in the first year of working carried 5,000,000 passengers and earned £20,000. It had been found in the new conditions of tramway enterprise impossible to undertake services on the terms of the Tramways Act, 1870, and in consequence it had been necessary to arrange special terms, especially as to wayleaves and conditions of purchase. In the Isle of Thanet he gave the local authorities power to purchase at 42 years on paying the value under the Act of 1870 with 25 per cent. added for the goodwill of the concern. In the case of the Hastings tramways there was a right of purchase at 25 years, the price to be the value of the undertaking as a fair going concern. The agreement with Renfrew and the other local authorities was that they should be entitled to buy what was in their own districts without going to Parliament; the distinction in the case of Paisley was that they were to have the power of purchasing the whole undertaking, but Paisley must go to Parliament and show that there was a public case in the purchase, and, of course, it would be open to any of the other local authorities to oppose the bill. He was the sole promoter of the present undertaking. The Renfrew agreement provided that the Corporation might purchase the tramway within the burgh as a going concern at a fair market value at 25 years; while the Paisley agreement provided for purchase at the original cost.

Mr. ERSKINE POLLOCK, for the Glasgow and Renfrew District Railway Co., submitted that their case was a particularly hard one, because their railway had only been sanctioned in 1897, and was not yet completed. The railway was designed for suburban pick-up traffic, just the class of traffic which the tramway was designed to serve. In these circumstances, he submitted that Parliament, having sanctioned the railway, should not subject it to this competition until it had had an opportunity of proving its usefulness.

Evidence on behalf of the other opposing railway companies was then heard, Mr. WORSLEY TAYLOR, for the Caledonian Co. and the Clyde Navigation Trustees, contending that if tramways were to be made, they should be made by the Corporation of Glasgow. Evidence for the Corporation of Glasgow was then taken and Mr. PEMBROKE STEPHENS said the promoters would be prepared to give the Corporation of Glasgow running power over tramway No. 7 from Govan to Renfrew if, upon corresponding conditions, the Corporation gave the promoters running powers over their system to Glasgow.

Evidence on behalf of the Glasgow Corporation, the Lanark County Council, and other opponents having been given, the CHAIRMAN intimated that the Committee had decided that tramway No. 7 (Renfrew to Govan) must come out of the bill. With this exception the preamble of the bill was passed, the clauses adjusted and the bill ordered for report to the House.

S.E. AND CHATHAM RAILWAY AND FOLKESTONE, SANDGATE AND HYTHE TRAMROADS BILLS.

On May 21, the House of Lords Committee, presided over by Lord Brougham, considered the Omnibus Bill of the S.E. and Chatham Railway Co., which relates to the construction of a junction railway line from New Romney to Hythe. The proposal was opposed by the Sandgate and Hythe Electric Co. (Ltd.), who have a bill before the same Committee seeking powers to construct tramroads from New Romney to Folkestone to be worked by electricity.

Mr. LITTLER, Q.C., for the railway company, said the proposed line would be 8¾ miles in length, would run from New Romney to Hythe, and would enable passengers travelling between those places by rail to save the present long detour of 35 miles viâ Ashford. The line would be worked by steam locomotives up to a point about three-quarters of a mile from Hythe, where it would form a junction with the company's own tramways, from which point it would be worked by electricity on the conduit system as far as the commencement of a short line to be constructed connecting the tramway with Hythe station. The only opposition came from the Sandgate and Hythe Electric Co., who sought by their bill to form in connection with their existing tramways a communication between Romney and Hythe. But then tramways would run, if authorised, along the highway inconveniencing the traffic on the high road, especially as it was proposed to carry goods as well as passengers. There was, he contended, no justification for their scheme, when there was a railway company prepared to give a properly constructed railway off the high road.

Mr. ALFRED WILLIS, manager of the S.E. and Chatham Railway, explained the proposals of the bill. He said that for many years the railway companies had proposed schemes to connect Hythe, Folkestone, Newchurch, and Dymchurch, the general idea being to connect the lines of the two companies, and have a through service from Ramsgate to Portsmouth. At a point outside Hythe, on the new line, there would be exchange stations, where the steam locomotive would be removed, and an electric motor put on, and the train taken over the tramway to Hythe station. The advantage the War Office would get by having connection between Shorncliffe and Lydd for heavy traffic would be important.

Mr. TEMPEST, engineer to the railway company and to the scheme, said the proposed line presented no engineering difficulties, and its cost would be £62,800. Electric traction was more suitable for the heavy gradient from Hythe station to the existing tramways. By the construction of the proposed line all the towns on this coast would be put in communication on the same gauge from Hastings to Margate and even along the Thames. The company's rolling stock could run over the tramway rails. It was possible that different trains might have to be used from the point where electricity was substituted for steam, but in cases of emergency any stock might be used.

After local evidence had been taken in favour of the new railway, the Committee decided to hear the case for the Folkestone, Sandgate, and Hythe Electric Tramroads Bill before deciding upon the proposals of the Railway Co.'s bill.

Mr. MOON, for the Sandgate and Hythe Electric Co., submitted that the scheme of the railway company was a hurriedly conceived one, and was not anything like so well calculated to meet the requirements of the district as the tramways scheme, which would give through communication from Folkestone to Hythe, Sandgate and New Romney. The tramway service would afford far better facilities for the purpose of Shorncliffe Camp, and would much better serve all the needs of the War Office. The trams were to be constructed along the public road, and all the local authorities, with the exception of the Folkestone Corporation, were in their favour.

Evidence was then given in support of the Electric Company's bill, and a number of local witnesses, including the Vicar of Sandgate and the Mayor of Hythe, expressed themselves in favour of the tramways.

Mr. S. P. SELLON, engineer to the scheme, said the tramways would be worked by electricity on the overhead trolley system. In Dover, where he had constructed tramways, the whole population was carried 60 times in each year. The length of the proposed tramways would be 17 miles. The generating station would be erected between Hythe and Dymchurch. He had ascertained the views of the local authorities as to the communications necessary for the district. They were very anxious that the tramways should form a continuous route throughout the district. A clause had been arranged by which any contract with the local authority for the purchase of any portion of the undertaking would contain provisions to secure the future working of the tramways as a continuous system. His company would take over the electric lighting order that Sandgate was promoting, as it was important from the point of view of the consumers that the company which supplied the energy for the tramways should supply the electric lighting. Sandgate had been offered by his company terms for electric lighting which could not have been offered apart from the tramways scheme. The electric cars would be exceedingly well supplied with brake power, and could be stopped when running at 8 miles an hour within their own length. The cost of the scheme would be for permanent way and general construction £131,518, with an additional sum for equipment. In trying to enter Folkestone they were seeking to carry out the wishes of all the other districts. If Folkestone would agree to give his company running powers into the town they would be prepared to hand over that portion of the scheme to the Corporation so that they might construct their own tramways and connect them up with theirs.

Sir CHARLES RIVERS WILSON, Chairman of the Sandgate and Hythe Electric Co. (Ltd.) said he was also the Chairman of the British Electric Traction Co. The relations between the Sandgate and British Cos. were that the Sandgate Co. was the child of the British Co., and was called into existence by it, and whatever present or future liabilities it might have will entirely fall upon the British Co. The British had about 40 affiliated companies now working tramways and light railways. The reason why these companies were not carried on in the name of the British Co. was purely one of administrative convenience. The British Co. exercised general supervision over the affiliated companies by means of their officers. The British Co. were in the present instance under agreement to provide the capital necessary for the promotion of the present bill, and the carrying out of the scheme if authorised. All the money required by the promoting company would be found for them by the British Co., the capital of which was £1,200,000 ordinary and preference shares, and £600,000 in debentures. That was the authorised capital, and of that £450,000 had been raised by ordinary shares, £500,000 by preference shares, and £350,000 by debentures, making a total of £1,300,000, leaving unexhausted means of about half a million. The British Co.'s £10 shares had been as high as £17, they were about £14 now. The debenture stock stood at £125, and the preference shares at a considerable premium. The shares of one of the affiliated companies—the Potteries Co.—had risen to as high as 100 per cent. premium. There was no doubt about the necessary capital being raised for the present undertaking if the bill passed. Only six of the British Co.'s affiliated undertakings had as yet been electrically equipped, but some 80 per cent. of them were working,

Digitized by Google

although the work of reconstructing and electically equipping the tramroads had not been completed.

After hearing witnesses and counsel in opposition to the tramway scheme, Mr. CARPENTER, mayor of Folkestone, said there was a balance of opinion in Folkestone favourable to tramways, but the town was virtually unanimous in favour of municipal tramways. The Corporation had pledged themselues to construct tramways in the future. In regard to the gap between Folkestone and Sandgate, the Town Council would co-operate with the outside authorities to fill it up. They would rather deal with the S.E. Railway or the outside authorities than with the promoting company. The Corporation had formed a sub-committee to bring up a tramway scheme, and a rough plan (produced) had been drawn up. The plan might be similar to that of the company, but they were at present trying to keep this outside company away. He pledged himself as Mayor, which was as far as he could go, to come to Parliament with plans next October.

Mr. MOON said all the Electric Co. asked for was that the tramways should not be blocked at the entrance of Folkestone; that running facilities should be given either by lease or Board of Trade intervention.

Re-examined, Mr. CARPENTER said the ratepayers would willingly pay more to have the conduit system of electric traction rather than have the overhead system.

Mr. BAKER, the chairman of the Public Works committee of the Corporation, said they ought not to have the overhead system in Folkestone. The goods terminus proposed by the Tramway Co. was within 100 yards of his property, which it would considerably depreciate.

Mr. POPE, Q.C., for the Railway Co., said the tramways could not pay unless the views of the principal local authority within the area were outraged by the company being enabled to construct tramways within Folkestone. To meet the objections raised, the Electric Co. had said, let the Corporation make their own tramways, but bind them to lease them to no one but us. The scheme was a bad one in a financial sense. There would be no traffic over the outside lines in the winter, and he could quite understand why the British Electric Co. were anxious that these tramways should be constructed not by themselves but by an affiliated company. He asked the Committe to reject the tramway scheme.

Mr. MOON, in replying for the Tramway Co, said in regard to the Folkestone opposition it was admitted that tramways were required, and that the tramways the Corporation had in mind were similar to those proposed by the company. The only question was who should construct the tramways. His company were willing to take their bill up to the boundaries of Folkestone. In the present state of feeling there they ought not to be so limited, but the public ought on fair terms to the Corporation of Folkestone and to the company to get the tramways. If the Corporation chose they could construct the lines in Folkestone on the conduit system, and the company could use the overhead system up to the boundaries of the borough. Cars could be run from the one system to the other, and passengers need not change cars.

The Committee decided to sanction the railway from New Romney to Hythe, provided it were constructed as a continuous railway throughout, so that no change of carriage would be required, the period for construction, as the line presented no engineering difficulties, to be three years in place of five, as asked for in the bill. The Committee further decided that the preamble of the bill of the Hythe and Sandgate Electric Co. for the construction of tramways from New Romney to Folkestone was not proved.

MUNICIPAL TRADING.

The Houses of Lords and Commons Joint Committee on Municipal Trading met again on Friday last, the Earl of Crewe presiding.

Mr. ALBERT GRAY, counsel of the Chairman of Committees in the House of Lords, stated that during the past two sessions every proposal on the part of a local authority or company to manufacture gas fittings had been struck out of the bills containing them. In this respect, therefore, the practice of Parliament had tended to check municipal trading. With regard to electric lighting, the power to supply outside the local authority's district had been given ever since the passing of the Electric Lighting Act of 1882. Manchester supplied electric light to nearly all its suburbs, and he believed that the Corporation of that city was going to run tramways both in the city and the neighbouring townships. If a local authority was in possession of electric lighting plant it might compel a company to take its electric energy from it. This, of course, meant a saving, and there was no reason why there should be a double electric plant in a town where one would do.

The CHAIRMAN: The local authority would in that case be more likely to purchase the company's undertaking?—They might be.

The power to manufacture electric fittings has recently been struck out of electric lighting bills also?—Yes. Witness added that the veto which a local authority had over a tramway scheme promoted by a company appeared to him at the present day to work very badly. He thought it was the intention of Parliament that the consent of the local authority should be what might be called a "clean" consent. There had, however, unfortunately sprung up a practice of demanding conditions, and in some cases a demand was made that the local authority should share the profits of the undertaking during the term of the company's tenure. It was obvious that when such a demand was made a company was in a cleft stick. The clauses introduced into private bills under this system were very frequently of great length, varying inversely to the size and importance of the local authority. No complaint could be made of the conduct of the great municipalities in this matter, but the smaller municipalities seemed to think that they were entitled to get as much as they could out of the companies. A provision for the payment of an annual rent to a local authority was not regarded by Parliament as a proper one, and was invariably struck out. Tramway companies were sometimes compelled to allow the use of their electric wire poles for electric lighting, for sewer ventilation, and for advertisements. One tramways bill, introduced in the present session, contained a clause providing that free passes over the tramways should be given to officials of the corporation, while another provided that a tramway company should pay a corporation, as an annual rent for the use of the streets, £10 a year per mile for 10 years, and £20 per mile in subsequent years.

The Committee then adjourned to June 15.

WEST BROMWICH CORPORATION BILL.

The Omnibus Bill of the West Bromwich Corporation, which seeks powers for the construction of electric tramways and for additional electric lighting powers, &c., was considered by a Select Committee of the House of Commons last week.

Mr. FITZGERALD (for the promoters) said that at present the Corporation did not own the tramways within the borough. The South Staffordshire Tramways Co. had never been a successful company, and the lines had been for many years past in a bad state of repair, and the whole track required to be taken up and relaid. The line within the borough was worked by steam, and the Board of Trade had never granted a licence for more than six months at a time. The lease of the trams expires in February, 1903, and the Corporation had decided to exercise their option of purchase. At the present they had no power to work tramways, and now sought these powers, and to work by agreement tramways situated outside the borough which could be best and most economically worked as a part of the whole system. By clause 7 it was proposed to authorise the Corporation to purchase by agreement any authorised tramway outside the borough which formed a continuation of the tramways within the borough; and clause 8 enabled the Corporation, when the local authorities decided not to purchase and work the lines, to do so as a part of the whole West Bromwich system.

Mr. SYDNEY MORSE, solicitor for the South Staffordshire Tramways (Lessee) Co., objected to the Corporation spending money for working the tramway systems of the local authorities against the South Staffordshire Co., who were working merely on money raised by shares in the ordinary course.

The CHAIRMAN pointed out that the promoters brought no specific scheme before the Committee in this connection, but proposed to take general powers ranging all over the place.

Mr. FITZGERALD said he would be willing to have the powers restricted to Wednesbury, Tipton, Oldbury, Smethwick, and Handsworth in the case of their being able to come to an agreement with those local authorities in the event of their acquiring the tramways in their district.

Mr. MORSE urged that no special circumstances had been proved for the special powers asked for. On the other hand, the South Staffordshire Co. had good ground for asking for good terms as against the Corporation of West Bromwich. It was difficult to make horse or steam tramways pay, but it was proposed to work the system electrically, and the company had made arrangements with those fully able, financially and from an engineering point of view, to carry out all that was required in the district.

After deliberation the CHAIRMAN said the Committee would permit the Corporation to go outside their boundaries for such parts as had been specially named, viz., small lines in Handsworth, Wednesbury, Tipton and Oldbury. In dealing with the electricity clause, the chairman called attention to the report of the Local Government Board on the clause, which said: "Under the provisions of this clause the Corporation would be empowered to supply electrical energy for the working of tramways and light railways an indefinite distance from the boundaries of the borough, and to construct such works as may be necessary for the purpose. The Board suggest that before approving of the clause the Committee should require evidence of the grounds on which those powers are sought by the Corporation."

Mr. A. D. GREATOREX, borough surveyor, said the Corporation had an electric light undertaking, and were building a generating station, the site of which had been selected, with the object of supplying electricity both for traction and lighting.

Mr. FITZGERALD undertook to amend the clause by introducing the suggested limiting words.

LEGAL INTELLIGENCE.

Chamberlain and Hookham v. The Corporation of Bradford.

Mr. Justice Farwell delivered judgment in this case on Friday last. The hearing of the case was reported in our issues of May 11, p. 99, and May 18, p. 137.

JUDGMENT.

Mr. Justice FARWELL said: The plaintiffs seek for an injunction to restrain infringement of this patent, No. 4,225, of 1887, for improvements in electricity meters,* parts of which improvements are applicable to dynamo-electro generators and motors. The defence is a denial of the infringement, and a plea of the invalidity of the patent. The plaintiffs' patent has been before the court in another action, tried before Mr. Justice Wills, in February, 1897,† when, on the evidence before him, he granted the relief asked for against Johnson, the defendant in the action, and gave the usual certificate that the validity of the patent had come in question. I propose to adopt the judgment of Mr. Justice Wills on all questions of

* An abstract of this patent is given in *The Electrician* of May 11, 1900, p. 101.

† See *The Electrician*, Vol. XXXVIII., pp. 622, 665. (*Judgment*) 839.

Digitized by Google

law determined by him in that action. The plaintiffs' complaints in the present action are confined to claims 1 and 3 in their specification. With respect to the first claim, Mr. Justice Wills has held, and both sides agree, that this is a claim for a combination, that is to say, that the invention consists in the combination in the plaintiffs' meter of a number of appliances either for the purpose of producing a new result or for the purpose of producing an old result by new means. The appliances combined may be either new or old, or partly new and partly old, and the patent may, if aptly framed, effectually claim protection for such of the appliances as are novel as subordinate integers, in addition to the invention contained in the combination and protected by the patent. It is contended in the present case that the third claim is not merely a branch of the combination, but is also an independent integral claim. It is also contended by the plaintiffs that they introduced for practical purposes a new principle or idea in the construction of meters. It is, of course, well settled that a mere idea or principle cannot be the subject matter of a patent; there must be some concrete form to which the principle is applied; and that concrete form must be defined and limited, for if the claim is in general terms for every mode of carrying the principle into effect it becomes a claim to the principle itself, and fails.

I propose to apply these propositions in determining this action. The first question that I have to consider is that stated by Lord Justice Cotton in "Proctor *v.* Bennis," 31 Chancery Division, p. 754: "Has the plaintiffs' combination in substance been taken; have the defendants though not taking exactly the whole combination patented, taken by slight variations or mechanical equivalents, the substance of it, so as to produce the same result by practically the same means." In answering this question, I have to bear in mind the distinction pointed out by Vice-Chancellor Wood, in "Curtis *v.* Platt" (3 Chancery Division, 135) that "Where the invention is for the production of a result already known and attained the protection afforded by the patent is confined to the particular means pointed out by the specification, and the same result may be attained without infringement by another person by the use of mechanical equivalents." In other words, the invention of a combination of processes leading to a known result does not prevent other persons from arriving at the same result by a combination of other processes; but if the result is novel in that it produces a new instrument or involves the practical application of a new principle, the defendant infringes by substituting known equivalents. To use Lord Bowen's words (36 Chancery Division 764) "When there is really an ingenious novelty, the idea that the combination will produce a new result, that novelty in the dea is part of the merit of the very combination."

Now in this case the object to be produced is an electricity meter for lighting and motor purposes; such meters were not new in 1887. Electricity as a mode of lighting was well known, certainly before 1882, when the first general Act relating to electric lighting was passed, and meters for the purpose of measuring the article supplied were a necessary adjunct for the commercial success of any system of lighting. Mr. Ferranti made meters in 1884, and Edison at or before the same time. These meters were, of course, of a different type to the plaintiffs, but they were not the less instruments for measuring electricity. But then it is said that the plaintiff discovered and applied for the purpose of his meter a novel principle—namely, that magnets could be at the same time permanent and powerful. He stated that before 1887, although permanent magnets had been known and used as constant with a weak field, yet when magnetised so as to become powerful their constancy was not only unknown, but not believed in. He said in effect that permanent magnets were really considered inapplicable for the purposes of a meter by reason of incompatibility of power and constancy, a fallacy which he considers he exploded. This is material from the point of view of the principles which have already been stated, for if this idea was really novel it would form part of the invention found in the combination within the meaning of the words of Lord Bowen quoted above. But on the evidence I find the contrary to be the fact. I think I do no injustice to the plaintiffs if I look at their own specification to assist me in judging of the probability of the reality of this alleged discovery. One would expect to find there a statement of the new principle, and not the less because it was destructive of an old fallacy. If a patentee had really discovered for the first time that power and constancy were compatible, and knew that all other electricians believed them incompatible, he would never direct the construction of an instrument with very powerful and very constant permanent magnets without calling attention to the fact that the existing belief with reference thereto was fallacious. He would surely know that the expert, uninstructed as to this, would at once cast aside his specification as that of an impracticable dreamer. I have, further than this, the oral evidence of witnesses of experience and standing entirely contradicting the plaintiffs' statement. Further than this the specification really states no tangible principle at all. All magnets necessarily have some constancy and some strength; to say that magnets are to be used which are both powerful and constant is imply to state that you must make your magnet as powerful as is consistent with its constancy; it becomes a mere question of degree, and no principle is involved, and no practical direction given in the specification. Further, it is clear on the evidence, that before 1887 the practice of ageing powerful magnets and thereby making them constant was well known. There was nothing to prevent the defendants from rendering their magnets constant by artificial ageing, and from using two or three if one was found insufficient; and the defendants, in fact, used formerly three and now use two comparatively weak magnets which have been rendered constant by a very special process of ageing described by one of the witnesses. I conclude, therefore, that there is neither novelty of object aimed at nor of idea or principle involved, and I approach the consideration of Claim 1 as a combination patent pure and simple.

Now, the object aimed at by the plaintiffs and defendants are different in this respect. Both make a meter; but the plaintiffs' is a current meter, the defendants' is an energy meter. The distinction is, to my mind material. The current meter measures current only, and is incapable of measuring anything else. The energy meter measures the energy—that is, both the pressure and the quantity. The Board of Trade unit is energy, not current. Mr. Ferranti stated the essential difference to be that in an energy meter the two parts of the motor—namely, the armature and the field—must be connected, the one in circuit with the lamps to be measured, the other across the circuit so as to receive the voltage of the circuit. The current meter deals only with the main current of the circuit flowing to the lamps. Further, it is essential to a current meter, and is so stated in the specification, that there must of necessity be an electromotor with a constant or nearly constant field. In an energy meter such a constant field would be destructive. Further, the energy meter will not directly measure current at all. It is true that if you have, in fact, a constant potential, you can calculate from your energy meter, and the amount of energy shows thereby what amount of current has passed. Mr. Moulton founded an ingenious argument on this. He said that by Act of Parliament the potential was allowed to vary only to the extent of 3 or 4 per cent., so that it must be practically constant; and that at Bradford the defendants' supply was so good and regular that the potential was practically constant; and, further, that the defendants knew and intended that their meter would measure current, in effect, because of the use by the defendants of a compound winding for the purpose of starting. This was originally the second claim in the patent, but was struck out, and is admitted to be old. It is said, however, that this compound winding involves, as a necessary consequence, the existence of a constant potential—constant that is in the sense that a meter supplied with this and adapted for a circuit of 100 volts could not be used on a circuit of 200 volts. All these contentions appear to me to be fallacious. The fact that the defendants at Bradford have hitherto supplied electricity at a constant uniform pressure does not render it unnecessary to have a meter capable of measuring whether they do or do not keep up such uniformity. To hear is not necessarily to obey, even between an electric lighting company and the Board of Trade, and to say that the defendants have not proved that they have deviated in the past from the Board of Trade regulations is to attempt to turn their virtue against them in a way quite unwarrantable. The point as to the compound winding also comes to nothing. It is usual to have currents of either 100 volts or 200 volts, and it is not usual to vary the voltage more than a small percentage. The use of an old appliance for a circuit of a particular voltage is in no way inconsistent with the measurement of the variations of energy possible within the range of fluctuation usual in such a circuit. It is, perhaps, not immaterial to add that in the case before Mr. Justice Wills the defendant used a current meter, and the present plaintiff in that case relied, and in part succeeded on the distinction between energy and current meters, and further, the plaintiff told me that he himself gave evidence as to the distinction, and accepted his counsel's statement that he had taken the simpler problem. Further, the plaintiff, at about the same time that he took out his present patent, obtained another patent for an energy meter, and accurately described his energy meter as combining the parts of electro motors of the kinds described, whereby the driving force acting on its armature is proportional both to the quantity of the current to be metered and to its electromotive force.

Further, I hold on the evidence that the defendants' meter will work with alternating currents, and that a meter made according to the plaintiffs' specification would not, so that the defendants' meter not only measures that which the plaintiffs' will not, namely, energy, but is also appropriate to currents to which the plaintiffs' is not. The plaintiff is in this dilemma—if he claims that his patent extends to alternating currents he has given no directions by which an instrument could be made to work therewith, and his patent would therefore be void. If, on the other hand, he does not claim that it is within his patent, he admits that the defendants' meter performs an important function that his cannot. It is not necessary for me to determine on which horn of the dilemma the plaintiff is impaled, but I will assume the latter as being more favourable to him. and I do this the more readily as the defendant does not press me to hold the plaintiff's patent bad unless it is absolutely necessary to his case. It appeared in evidence that in 1887 alternating currents were little used in a manner which required to be metered, and that no machine for alternating currents has, in fact, ever been made or attempted to be made in accordance with the plaintiffs' specification. I hold, therefore, that the object aimed at and attained by the defendants' meter is both more extensive and more practically useful than that attained by the plaintiffs'.

Then it is said by the plaintiffs that the defendants have taken the material part of their combination, and have used the governing idea suggested by the inventor. Both the meters necessarily have a motor to supply the driving power and a magnet to supply the braking power and a commutator. The great practical difficulty experienced by inventors in devising a form of motor that would work was static friction. As Mr. Hookham put it, "The forces at our disposal that act for us are so extremely small that I should say that static friction which obeys the wrong law is our principal difficulty." In order to obviate this difficulty Mr. Hookham commences by enlarging and making as powerful as possible the forces which act in the right way. As he put it, "It is the exaggeration of the electrical forces which is as important as the diminution of the static friction." This diminution is effected partly by the mechanical contrivance of bars or anti-friction rollers, and (which he regarded as more important) by a commutator which acted by means of mercury cups instead of ordinary solid brushes. His complaint is, in fact, that the central idea—namely, the exaggeration of the electrical forces—is his idea, and is taken by the defendants. He admits that the defendants' commutator and other mechanical anti-friction contrivances are entirely different from his own; but so far as the combination claim is concerned (having regard to what I have already

Digitized by Google

decided as to the knowledge of the possibility of the co-existence of power and constancy in magnets), any argument in support of claim 1 must rest on the novelty of the use to which the idea of this exaggeration of forces is applied. The substance of the argument, as I understand it, was put thus by Mr. Moulton: The two things that Hookham found out were these:—(1) That he could have his brake so powerful in the way adopted by him that he could afford to have a large driving power, and (2) that he could made a commutator so frictionless that with that brake power he could get practical accuracy; and he says that the combination of these two steps was Hookham's invention, and ensured success. But I find as a fact that it was known before 1887 that you could, by the exaggeration of the electrical forces, render the amount of friction with which you had to deal less important. In addition to the oral evidence, I refer to Uppenborn's Paper of February, 1884,* Marcel Deprez's Paper, January, 1884,* and Ayrton and Perry's patent.* There always remained a residium of friction, too great to be got over by mechanical appliances, if any commutation that was known prior to 1887 was used in the meter. The new step taken by Hookham in his meter was that he invented a form of commutator with an ingenious arrangement of mercury cups whereby he avoided the friction produced (and then supposed to be necessarily produced) by brushes altogether. The real step in advance that Hookham took, as compared with Ayrton and Perry, was the addition of this commutator to the means for exaggerating the electrical forces which were then well known. Both Ayrton and Perry, Marcel Deprez, Siemens and the plaintiffs exaggerated their magnetic forces, but this exaggeration was not sufficient to ensure success for any of them. But the defendant uses a commutator of an absolutely different nature from the plaintiffs. They have solved another problem, and have shown that brushes can be successfully used if they are silver tipped, and if silver is used in other respects, as pointed out by the witnesses. This is not the case of a mere mechanical equivalent, but of a new appliance. The plaintiffs' case on claim 1 in my judgment fails entirely.

There remains claim 3, and as to that Mr. Moulton says that claim 3 is not a combination, but a subordinate integer, and he claims that his clients are entitled to an electricity meter, to a monopoly for permanent magnets, rendered permanent and constant by their special form, used to form either the brake or the armature field. Now, the plaintiffs' magnet is what has been called a compound or built-up magnet, and is absolutely dissimilar in form to the defendants'. The plaintiffs' is of a very special form. The defendants' is the common horseshoe, and the witnesses say that that form is a material circumstance in considering a magnet. If Mr. Moulton were claiming as his subordinate integer the particular form of magnet described in his specification and drawings, and no other, he might possibly rely upon Mr. Justice Wills's judgment as a decision in his favour. His Lordship says that Hookham did invent a form of permanent magnet with great splayed ends, where the continuity was broken. I understand this to mean a magnet such as is described in the specification as having very large polar surfaces closely fronting each other, so as to form a narrow slit in which the disc armature revolves. In the case before Mr. Justice Wills, the defendant used a magnet similar to the plaintiffs' magnet, and was restrained; but this will not be sufficient for the plaintiffs in the present case, and Mr. Moulton, in fact, claims a monopoly of all magnets with large polar surfaces close together. I have very great doubt whether such a claim could even be sustained. It is exceedingly difficult to say what is large in respect to surface and what is close together; and while I feel convinced that Mr. Justice Wills did not decide this point in any way that amounts to plaintiffs' contention, I am not quite sure that he meant to decide that the particular form of magnet was well claimed as an independent subordinate integer. I should myself read the third claim as subsidiary to the first, so that the novel form of magnet is claimed as one portion of a combination, and not as a separate invention. But however this may be, I am of opinion that the defendants' magnet does not come within any fair interpretation of the plaintiffs' description of permanent magnets with very large polar surfaces. Further than this, in my opinion permanent magnets with polar surfaces closely fronting each other so as to form a narrow slit in which the disc armature revolves were known before 1887, and there is no novelty in anything that the plaintiffs claim in claim 3 unless it be the particular form of their magnet. As Mr. Justice Wills puts it in his judgment, the idea of using the Foucault currents for producing braking action, is clearly not new. Nor is the idea, in a general way, at least, of applying this braking action to an electricity meter. He points out that it is described in definite terms in Ayrton and Perry's specification—the revolution of magnets in front of a disc being indistinguishable in principle from the revolution of a disc in front of the magnets. In addition to the evidence before Mr. Justice Wills, I have Siemens' energy measurer with Marcel Deprez's Paper thereon in 1884. Siemens' instrument had an axis with wings revolving in paraffin. Marcel Deprez suggested in 1884 an improvement upon this, by substituting for it a copper disc revolving between the poles of a permanent magnet, and he continues: "The rotation of the disc between the poles of the magnet will have the effect of developing in the interior of the disc induced currents following a well-known law which I formerly applied in my magnetic speed indicator, exercising on the magnet a magnetic force proportional to the first power of the speed." This accurately describes the defendants' machine. It is true that it does not describe any particular form of magnet, but ordinary horse-shoe magnets, with polar surfaces close to each other, were well known, and the magnetic speed indicator to which the writer referred, is described in a Paper dated 1881, which contains drawings of magnets, two of which (Figs. 5 and 7) are practically indistinguishable from the defendants' magnets. As a matter of construction of Marcel Deprez's Paper of 1884, I should say that the magnet that would be naturally taken by the reader in the absence of specific directions, would be one of the magnets shown in the drawings relating to the speed indicator therein mentioned. For these reasons I come to the conclusion that the plaintiff has failed to show any infringement of his patent, and it is therefore unnecessary for me to express any opinion as to the validity of the patent. I dismiss the action with costs, and I see no reason for making any distinction between the costs of the action so far as it relates to the validity of the patent.

The action was accordingly dismissed.

* See *The Electrician* of May 11, 1900, pp. 103 and 104.

Crompton and Co. (Ltd.) re Electrical Power Syndicato (Ltd.).

This case came before Mr. Justice Wright and a special jury yesterday.

Mr. BRAY, Q.C., said plaintiffs were the well-known firm of electrical engineers and contractors, and defendant syndicate was at present in liquidation, but the jury must not think it was insolvent, for the shareholders had had all their money returned with a dividend of 100 per cent., and there were assets which would be sufficient to pay a further dividend of some 250 per cent. It was a company that had done its work and was being wound-up because it had done its work, and plaintiffs claimed to have a title to some of its assets. The plaintiffs claimed that having rendered large services in the promotion, and after the promotion of the syndicate there was an agreement made by which plaintiffs and other companies which had rendered similar services, should have the right to be contractors to the syndicate for such electrical plant and machinery as they would in the ordinary course require. They had refused these contracts, the syndicate had repudiated all liability, and plaintiffs asked for damages, which would represent the profits they would have made on their share of the contracts. Alternatively they said they were entitled to be paid for services rendered. In 1896 Mr. Addenbrooke, of Wolverhampton, was proposing a scheme for establishing an electricity supply station in Staffordshire to supply electric energy to towns near Birmingham, where there were many manufacturing establishments. There was an enormous demand for power in this district. Mr. Addenbrooke, in order to carry out his scheme had to look out for some person of high standing in the electrical engineering profession, and under these circumstances he applied to Mr. Crompton. Interviews took place between Mr. Crompton and Mr. Addenbrooke and Mr. Albright (a co-director at the time with Mr. Crompton) who agreed to enter into the formation of a syndicate to carry out the idea. The company was incorporated on June 10, 1897, and after the scheme was gone into in great detail, it was arranged that Messrs. Crompton and Co., the Callender and Co., and Messrs. Thomas Parker should be contractors to the syndicate. They were to have the contracts which, had they been carried out, would have amounted to about £150,000 between them. Another syndicate was subsequently promoted, called the Midland Electric Corporation for Power Distribution (Ltd.), Mr. Crompton rendering some service. Subsequently resolutions were passed by the directors of the pioneer syndicate, referring to the three firms as being contractors for the syndicate, and offering them compensation in the event of the syndicate disposing of its rights. Plaintiffs, however, complained that no contracts had been given to them, and brought the present action.

The evidence of Mr. Crompton was read, to the effect that he, as managing director of Messrs. Crompton and Co., had many meetings with Mr. Addenbrooke, when details of the scheme were discussed.

In answer to one of the jurors, Mr. BRAY stated that plaintiffs had received nothing from the syndicate.

Mr. T. TERRELL, Q.C., for the defence, said there was no foundation in law for the action. The contract alleged a verbal arrangement made before the syndicate, which was sought to be charged with the contract, was registered. He submitted it was a contract outside the powers of the memorandum of association and could not be accepted afterwards by the syndicate as it was *ultra vires*.

In the result the parties came to terms, Mr. Terrell announcing that his clients would pay £750, without costs.

MUNICIPAL, FOREIGN & GENERAL NOTES.

Abercarn.—At a special meeting, last week, the District Council, who are opposing the Electrical Power Distribution Co.'s bill, agreed to appoint a committee to consider the question of themselves undertaking to establish electricity works, or joining with other local authorities in promoting a scheme of supply for the western valleys of Monmouthshire.

Adelaide (South Australia).—In connection with a note appearing in our last issue (page 193), we have received the following:—

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In the current *Electrician* is a paragraph stating that "Mr. W. G. Bingham has obtained a concession from the Adelaide City Council for the construction of electric tramways." All Mr. Bingham has obtained is a promise from the Adelaide Corporation to support and assist him in the promotion of a bill through the South Australian Parliament, to enable the compulsory purchase of the present 54 miles of horse tramways, 18 of which are in the city and 36 outside its boundaries, and which belong to some half dozen companies. Prior to the agreement between Mr. Bingham and the Corporation coming to light, the British Westinghouse Co. and the Callender Co. had effected agreements with the greater number of the present tramway companies for the purchase of their lines (as has, I think, been mentioned in *The Electrician*), and a bill is to be brought before Parliament this next session to enable them to convert the lines for electric traction. As it seems that the suburban councils support these companies, and will oppose Mr. Bingham's bill, the latters so-called "concession" from the Corporation of Adelaide, is a rather doubtful commodity.—Yours, &c.,

ADELAIDE KIAN.

Arbroath.—Mr. M. Buchan has been appointed consulting electrical engineer at a fee of £52. 10s., plus expenses (not to exceed £10), to prepare a report on the proposal to establish electricity supply works.

Bath.—It has been decided, owing to the increase in the price of coal, to postpone for the present the reduction in the charge for electric energy, which was to have come into force on June 24.

Beira.—In connection with the tenders recently called for in London, Lisbon and Paris for the erection and equipment of an electric generating station at Beira for lighting, traction and power supply, it is stated that the expense of hardening the roads to permit of the laying of a tramway track will prove to be very heavy and of a difficult nature, owing to the total absence of stone in the vicinity. The roads are at present entirely composed of soft sea sand. It will, therefore, be some time before the work is started.

Blackpool.—The electric tramway extension through Claremont Park to the Gynn is now open for traffic. The line was officially inspected by the Board of Trade last week.

The profit on the electricity department for the year ended March 31 is £1,170. The borough electrical engineer (Mr. R. C. Quin) estimates that the advance in the price of coal has reduced the profit from his original estimate of £2,300. A gross profit of £9,660, with a net profit of £2,185, is estimated on next year's working. On the Tramways department's working a profit of £12,000 is anticipated.

Board of Trade Intelligence Branch.—A committee has been appointed for advising the Board of Trade on the work of the Intelligence Branch of the Commercial, Labour and Statistical Departments. The committee will consist of Sir Courtenay Boyle (chairman), Sir Alfred Bateman (deputy-chairman), Lord Avebury, Sir F. Abel, Sir H. G. Bergne, Sir C. E. Bernard, Mr. F. Brittain, Mr. T. Craig Brown, Prof. Wyndham Dunstan, F.R.S., Mr. C. A. Harris, C.M.G., Sir Alfred Hickman, M.P., Mr. W. H. Holland, M.P., Sir Albert K. Rollit, M.P., and Mr. G. W. Wolff, M.P. The committee is appointed for five years, and Mr. G. J. Stanley, of the Commercial Department of the Board of Trade, who acted as secretary to the departmental committee on Commercial Intelligence, has been appointed secretary of the advisory committee. The first meeting of the new committee has been summoned for June 14.

Burnley.—The Council has come to terms with the whole of the opponents to their electric tramway scheme, and on Wednesday resolved to reconstruct and electrically equip the tramways within the borough on a gauge of 4ft. as soon as practicable after their acquisition by the Corporation. The borough surveyor (Mr. G. H. Pickles) and the electrical engineer (Mr. R. Birkett) have been instructed to prepare preliminary plans and specifications for the work, and in conjunction with the town clerk (Mr. A. Steele Sheldon) to make inquiries with a view to retaining the services of a consulting engineer.

"**Cassier's Magazine**."—The June issue contains articles on "Trade Possibilities in South Africa," "Sixty Years in British Iron Works," "Engineering Graduates from Universities," and "The Cost of Machine Work."

County Councils and Electric Lighting.—The Middlesex County Council have decided to oppose the bill confirming the Twickenham and Uxbridge electric lighting orders.

Court of Common Council.—At yesterday's meeting the Streets committee presented a report on the subject of the communication from the London County Council, asking the views of the Corporation on proposals for the construction of tramways from Farringdon-road to Ludgate-circus, from near the Mansion House to Putney-bridge viâ Queen Victoria-street, Victoria Embankment, &c.; and recommending that the Council be informed that the Corporation is not prepared to give its consent to the construction of such tramways within the City boundaries.—The recommendation was agreed to.

The committee also reported relative to an application from the Postmaster-General to take up the roadway pavement at the southern end of St. Bride-street and at Holborn-circus, for the purpose of forming a connection with the St. Bride-street, Shoe-lane, and St. Andrew's-street subways, erecting and maintaining throughout an iron and wood frame staging to support lead-covered telegraph wire cables; and recommended that no objection be offered to the proposed works, subject to the same being carried out to the satisfaction of the engineer, and to the Postmaster-General agreeing to pay such fees in respect thereof as may hereafter be prescribed for similar easements in the City subways.—The recommendation was agreed to.

Customs Duties.—The Argentine Customs law of 1900 imposes a duty of 5 per cent. *ad valorem* upon imported machinery and mains for electric lighting and upon automobiles of all kinds and spare parts thereof except car bodies. The duty on incandescent lamps has been decreased from 3·00 to 2·80 pesos, and has been increased on insulated wires and cables for electrical purposes up to 5mm. from 0·60 to 0·70 pesos. Amongst the goods entering Argentina free of duty are iron or steel fish-plates, transoms, &c., for electric tramway tracks, and all plant destined for the construction and working of electric tramways.

Darlington.—The Corporation have fixed the charges for electric current at 5d. per unit up to 1,000 units, 4½d. up to 3,000, and 4d. over 3,000, and a maximum of 2d. per unit for power, with special discounts to large consumers. A proposal that the Corporation should undertake to pay for the wiring of private houses and recoup themselves upon a gradual payment system has been referred to Prof. A. B. W. Kennedy for report.

East London Provisional Orders.—The Board of Trade have forwarded copies of the provisional orders for Limehouse, Mile End Old Town, and St. George-in-the-East, to the various local authorities, and have intimated that it is proposed to insert in the confirmatory bill a clause providing for the treatment of the three undertakings as one with that authorised by the Whitechapel Electric Lighting Order on the establishment of the new borough of Stepney.

Electric Light and Traction Bills.—Royal assent has been given to Electric Lighting Orders Confirmation (No. 2) Act (1900), the City and South London Railway Act (1900), and the Charing Cross, Euston, and Hampstead Railway Act (1900).

Electric Light Fixtures.—Section F of the catalogue published by Messrs. D. H. Bonella and Son (Ltd.), 58 and 60, Mortimer-street, Cavendish-square, London, W., is now ready, and deals with electric light fixtures for both indoor and outdoor work. An infinite variety of designs in bracket, pedestal, and suspension lights, and the accessories therefor, are shown.

Electric Power Scheme for West Yorks.—The Yorkshire Electric Power Co. have prepared a scheme for the supply of electricity in bulk for lighting and power in the manufacturing districts of West Yorkshire. Todmorden Council has decided to oppose the scheme, while Golcar has refused to pass any resolution on the subject.

Electrical Enterprise in Italy.—The great development of the applications of electricity to industrial purposes continues, and has caused increased imports of the requisite plant and the creation of fresh works for its production. The imported plant comes chiefly from Germany and Switzerland, and foreign capital from these two countries enters largely into the companies which have been formed under Italian names. A New York company is about to establish in Milan a factory for manufacturing plant and material required for electric traction on railways and tramways, which has hitherto nearly all been imported. A new industry which has now assumed considerable importance in Italy is the manufacture of calcium carbide, used chiefly for making acetylene gas. The United States and France occupy first and second places respectively as producers of carbide, Italy coming next. The Edison works at Paderno derives 13,000 H.P. from the river Adda, employed for generating electric current, which is taken by overhead cable to Manzo and Milan. Another similar enterprise, but on a larger scale, is on the point of completion.

The price charged for current varies according to the quantity of energy required, but the average at which the whole has been contracted for is £4. 4s. per kw. per annum for use during 12 hours per day, firms working 24 hours per day paying a slight increase. Current is to be transmitted by overhead cables. This enterprise is claimed to be the most important of its kind in Europe. The plans are due to the initiative of Italian engineers, and were made as far back as 1887, but their execution must be attributed in a large

Digitized by Google

measure to the assistance of a German, firm which has subscribed a considerable part of the capital of the company.

The experiments in electric traction recently made by the Mediterranean Railway Co. on its line from Milan to Monza, with accumulators, revealed certain defects, necessitating some considerable changes, and a partial and temporary suspension of the service. It is, however, believed that the modifications now in course of application will prove efficacious, and that the use of accumulators will prove best adapted to the short-distance journeys. The same company is about to try an experiment on a much larger scale on its line from Milan to Gallarate, on to Varese, Lavens, and Arona, about 73 miles of track. Water power for generating electric current will be obtained from the river Ticino, at Tornavento, where the necessary works are to be commenced immediately. The third-rail system is to be adopted. Orders for the electrical plant and apparatus required for this experiment have been placed, and are due for delivery in April next year. The cars will be built at the Mediterranean Co.'s own works.

At the same time, the Adriatic Railway Co. will adopt the trolley system on its line from Lecco to Chiavenna and Sondrio, 66 miles of track, power being obtained from the river Adda, near Morbegno. In this case the electrical plant and apparatus will be supplied by Messrs. Ganz and Co., and is due for delivery about April next.

The Officine e Cantieri Liguri-Anconitani, a metal-working undertaking established at Ancona, employing nearly 1,000 hands and occupying a works' space of 14½ acres, is using electric power to a large extent. Electric motors of an aggregate of 150 H.P. are employed, three large generating machines being installed, and an extensive battery of accumulators. The company is engaged in shipbuilding, the manufacture of railway plant, bridges, iron roofs, and similar enterprise.

La Societa per le Forze Idrauliche delle Liguaria has been formed in Genoa with a capital of £32,000 to acquire and exploit concessions for the utilisation of water power in the province of Liguria.

A concession has been granted by the Italian Government for the utilisation of the water power of the Caffaro between Ponte Caffaro and Bagolino. The electrical energy is to be employed for working the projected electric railway between Caffaro, Nave, and Brescia.

Electrical Enterprise in Poland.—In February last tenders were received by the municipality of Warsaw for the erection and equipment of electricity generating works, and the concession was granted to a German firm whose tender was the lowest of eight sent in. All the public streets are to be lighted electrically, and the horse tramway service converted to electric lines and considerably extended. No British firm tendered.

A German firm has secured the concession for the supply of electric current for private lighting, power and traction at Lodz in the same district, where the present mileage of the tramway is to be largely extended.

A Belgium firm is seeking a concession for converting the horse tram lines at Vilna into electric traction.

A concession for the construction and working of electric tramways at Lublin has been granted to a German firm.

The town of Czenstochan is being provided with an electric tramway service.

Electrical Inkless Printing—While the printing trade generally is sceptical as to the future of the process known as electrical inkless printing, and while those who look upon the process with some favour and anticipate for it some measure of success regard with misgivings the policy of the Electrical Inkless Printing Syndicate (Ltd.) in keeping the technical details of their process a secret, we think it right that the views of those who look upon the process as having been perfected and become demonstrably a real success should be given every publicity. The issue of Barnett's *Printing Trades Gazette* for May 9 contains the following leading article, setting out the merits of electrical inkless printing:—

To begin with, there is a very tangible economy, represented exactly by the difference in cost between the ink at present consumed and the current of electricity which will be consumed under the new method. We do not attempt to fix the saving in this respect, varying as it must do with the relative cost of ink and electrical supply. Black ink varies according to circumstances from 2½d. a pound in export quantities to two or three shillings for "cut" blacks; similarly, current from the mains ranges from 3d. per unit to 7d. or 8d. in different localities. [This should be 1½d. to 5d.—ED. *E*.] But this we are justified in saying—that the mean economy will be very considerable, as high as 70 per cent. The next point that occurs to us is, economy in machine construction. It abolishes the use of every inking appurtenance, such as the duct, distributors, and inking rollers, and their controlling parts. Conceive what this will mean on a great rotary. Then by eliminating the friction caused by moving the inking parts—the greatest in the whole machine—there must result an economy of power. Then we anticipate (but here we need the guidance of experience upon a broad scale) a sensible economy in the direction of make-ready and wear and tear, for the reason that the slightest contact between the printing surface and the paper will ensure the chemical changes necessary to produce a print of uniform colour. There is one point that among all the discussion that has surrounded the process we have not seen raised, but it will have its value. The addition of a pigment to the paper, as now practised, increases its weight, but 2oz. or 4oz. of paper electrically printed will not be increased in weight one iota. Therefore, for mailing purposes we may send an additional number of pages of matter in lieu of the ink upon which we now pay postage rate. Further, printed matter may be instantly backed up, instantly handled for any purpose whatever, without fear of set-off or smear. Instead of being the dirtiest department, as now, the electrical machine-room will in the early future be about the cleanest in an establishment. There will be no washing of formes, as the type will lift from the bed of the machine just as clean as it was laid there. This, again, implies less wear and tear of the type, as well as economy in time and material. Look at it from any point of view whatever, the change which is coming will be a boon to the printer. Mark, we speak in the future tense, not because we entertain any scepticism as to the practical solution of the method of electrical printing as evolved by the Electrical Inkless Printing Syndicate, but because it has not yet been reduced to the level of an every-day commercial possibility. This will come, must come, shortly Assuming the practical success of the process (a large assumption, notwithstanding the cocksureness of our contemporary), the case for electrical inkless printing is here well put. Assuredly the most tremendous revolution is foreshadowed by a success which we can at least hope for. The abolition of printers' ink, rollers, the dirt and "devil"-ment of the machine-room, to say nothing of hot-rolling and pressing and other devices to dry the printed sheets and give them a "finish," would be the greatest blessing ever conferred upon the great printing industry. For the publisher, the possibility of saving largely in the cost of postage of printed matter makes the subject an interesting one. Then why does the syndicate hold its hand?

Electricity Supply Failures.—At the Killarney (Ireland) Petty Sessional Court, last week, the Killarney Electric Light Co. (Ltd.) appeared to 28 summonses charging them with having made default on 28 occasions during March in the supply of electric current. The defence was that the failure was due to an accident to a steam alternator and to inability to get contractors to deliver plant which had been on order for some time. After hearing evidence the Bench inflicted a fine of 5s., with 5s. costs, on each summons.

Gift to the Nation.—Some time ago a committee of architects and representatives of the building trades organised a movement to provide homes of rest for discharged soldiers. A part of the scheme was the erection of six cottage homes with 100 beds and the necessary living and recreation rooms, workshops, and offices at Bisley, on land presented by Lord Pirbright. The whole of the work of erection, furnishing and fitting up has been borne by firms connected directly and indirectly with the building trades. The subscriptions in money and kind amount at the present time to about £19,000, and when completed the homes will be made over to the nation. The buildings are to be lighted by electricity, and an influential installation committee has been formed, of which Mr. W. G. McMillan (secretary of the Institution of Electrical Engineers, 28, Victoria-street, S.W.) is hon. sec. As soon as the specification for the plant, &c., now being prepared by Mr. Adrian Collins, is ready, the committee propose to appeal to the electrical trades for gifts, either in money or kind, to enable them to equip the homes satisfactorily.

Glasgow.—The Tramways committee recommend the Corporation to increase the salary of the manager of the Tramways department (Mr. John Young) by £150 per annum, making his salary £1,400.

Gloucester.—An inquiry was held here last week into the application of the Corporation to borrow £9,425 for electric lighting, and £8,575 for a refuse destructor. The town clerk (Mr. G. S. Blakeway) explained that £43,450 had already been sanctioned, and this sum had been overspent to the extent of £19. 10s. The new loan was for extensions of the plant and mains. The consulting engineer (Mr. Robert Hammond) gave technical details of the proposed extensions, which were rendered necessary by the increasing demand for current. The present position, Mr. Hammond said, completely justified the Council in laying down another 300 kw. set, by which the capacity of the works would be doubled. This would bring up the total effective capacity to 600 kw., after allowing 300 kw. as reserve. The experience of Gloucester had been identical with that of another cathedral city (Canterbury), namely, that by some diligent canvassing they had absolutely filled up the whole of their plant before turning on the current; 135 applications for the light had been received for a total equivalent of 13,350 8 c.p. lamps. The public lighting would require 2,000, and the power at the generating works 200, or a total of 15,550 lights. The actual commercial capacity of the works was for 10,000 lights, so that they required plant to provide for another 10,000 lights, to bring it up to 20,000. The provisional contracts for the extension plant had been obtained, subject to the sanction of the Local Government Board. In reply to a question by the Inspector, Mr. Hammond said that he considered that before Gloucester reached the limit of the electrical plant that would be required to supply the whole city they would require about 2,000 kw. They had now 600 kw., and were asking for 300 kw. more, and he thought they would want within the next five years plant three times as large. The 13,500 lights that application had already been made for were, as it were, only sample lights, for many would-be customers were

Digitized by Google

only waiting to see them lighted before becoming consumers themselves.

Hamburg.—A project for the construction of a mono-rail line in Hamburg has been submitted by the Continentale Gesellschaft für Elektrische Unternehmungen. Stringent tests are being carried out by the works department of the municipality. The company seek a concession for 50 years.

Horsham.—Formal application for a loan of £15,000 for electricity works has been made.

Hull.—The annual report of the Electric Lighting committee for the year ended March 31 was presented at the last meeting of the Electric Lighting committee. This is the seventh year's working of the undertaking, and at the beginning of the past financial year £94,953. 12s. 10d. had been expended in buildings, plant and equipment, and during the year the committee incurred further liabilties to the extent of £38,843. 9s. 11d. The total capital expenditure is £133,802. 2s. 9d. Two 800 H.P. units were erected during the period, and on March 31 there were 1,326 consumers connected, taking 940,192 units of current, during the year, against 960 consumers and 749,690 units in the previous year. The committee have 54 motors taking supply from the mains, of sizes varying from $\frac{1}{6}$ to 35 H.P. many of which have been connected during the past year, and a 50 H.P. motor will shortly be connected. The gross receipts were £19,290. 12s. 7d.; expenditure, £10,631. 3s. 11d.; gross profit, £8,659. 8s. 8d.; less contribution to sinking fund, £2,693. 15s. 1d.; interest on loans, £3,229. 10s. 3d.; depreciation of meters, £812; leaving net profit £1,924. 3s. 4d. Although more units of electricity has been generated, and a larger number of consumers connected, a decrease of £1,736. 2s. 9d. in the net financial result has occurred, with an increased generation of 190,502 units This was owing to reduction in the charge per unit, and to the increase in price of coal and increased staffing. The rating authorities had increased the rateable value from £616. 15s. 6d. to £871. 9s. 2d. On the other hand, there was a substantial reduction in the general establishment charges. The report has been adopted.

Leeds.—The estimates for the ensuing year were considered at the Corporation meeting on Wednesday. The Lord Mayor (Ald. Gordon) said that obviously with the need for extensions of the electric light and tramways undertakings, they could not stop expenditure. They intended to levy pretty heavily on the trading concerns in order to help the income of the city to meet its expenditure. They proposed to take £6,127 from the tramways and £4,000 from the electric lighting department. The profits on electric lighting amounted to £8,046. 4s, £4,046 4s. of which would go to reserve, which would then stand at £8,287. 2s. 9d. The gas concern did not figure as a contributor this year, owing to the increase in the price of coal.

Light Railways.—Notices of intention to apply to the Light Railway Commissioners for orders to authorise the construction of light railways have been given by:—

Rhyl and Prestatyn Light Railway Co. (extensions).

Hyde Corporation, for Hyde and Dukinfield.

Staines and Egham Light Railway Co. (Ltd.), for Staines and Egham.

Kidderminster and District Electric Lighting and Traction Co. (Ltd.), for Kidderminster and Bewdley.

North Wales and District Light Railway and Electric Power Syndicate (Ltd.) from Pwllheli to Nevin.

Auxiliary Light Railways and Tramways Co. (Ltd.), for Blackburn, Whalley, and Burnley district.

International Electric Traction and Power Syndicate (Ltd.), from Stockton Heath to Runcorn.

Southwold Railway Co., to alter the 3ft. gauge of existing railway between Halesworth and Southwold to 4ft. 8½in., to raise further capital and to construct a railway from Southwold to Kessingland.

Power and Traction (Ltd.), to construct the Nidd valley light railway.

British Electric Traction Co., Sheerness and district light railway, Kingston and Surbiton and district light railways (extensions), Jarrow and South Shields light railways, Durham and district light railways, and the Barnsley and district light railways (extensions).

Bath Corporation, Bath and district light railways.

John Fell, John Lewis, W. J. Kershaw, and others, Mansfield and district light railways (extensions).

A. Anderson and A. Brown, Warrington and Northwich light railway (western extensions).

Sheppey Light Railway Co., to amend Sheppey Light Railway Order (1898) and to authorise compulsory purchase of land.

The Todmorden Town Council will oppose the Todmorden and Bacup light railway scheme.

London County Council.—At Tuesday's meeting it was agreed to loan Battersea Vestry £20,000 for electric lighting, and St. Martin-in-the-Fields £6,010 to defray the cost of providing lamps, standards, &c., for lighting the streets within the parish.

The Finance committee reported that on March 6 they received the application of Islington Vestry for sanction to borrow sums of £56,261 and £13,200 for electric lighting, and stating that they (the committee) were unable to recommend sanction to more than £38,000 and £10,000 respectively, owing to their being unable to obtain from the Vestry certain details of information. They had since been furnished with these particulars, and now recommended that sanction be given for the balances. Approved.

It was agreed that the report of the Highways committee dealing with the resolution passed at the Guildhall Telephone Conference on Feb. 1, 1899 should be withdrawn.

The Highways committee also presented a report upon the present position of the litigation and negotiations between the Council, the National Telephone Co., and the Post Office. The committee calls attention to the action of the St. Marylebone Vestry, which, on May 3, decided to grant the application of the National Co. for permission to lay underground lines in various streets of that parish. The Vestry has been informed that the Council cannot adopt the view taken by the National Co. that so long as terms can be arranged with the road authorities as to underground wayleaves the consent of the Council is unnecessary. The Vestry are further informed that its action has a tendency to weaken the Council's position in "securing favourable terms for telephone subscribers in London as regards intercommunication between the National Co.'s system and that about to be established by the Post Office." Mr. Benn, in presenting the report, stated that if the tariff of the telephone service to be established by the Government should prove to be unfavourable it would become imperative for the Council, in conjunction with the City authorities, to apply for a municipal licence. Col. Ford said it was most unfair and ungracious for the Government to step in and take the metropolitan area for its telephone service when, as in the case of Glasgow, this area ought to be available to the Council in relief of the rates.

Lymington.—The Lymington Electric Light and Power Co. have submitted alternative schemes for the electric lighting of the streets for five years. The first scheme would cost £275 per annum, and the second £322. 10s, the terms including supply of current, maintenance and repairs.

Maidstone.—An inquiry was held last week into the application of the Council to borrow £40,000 for electric lighting and dust destructor purposes. Mr. C. H. Smith appeared in support of the application. He said that a provisional order was obtained in 1892, and the area covered the whole borough. The Corporation had been several times pressed by the Board of Trade to carry out the provisions of the order, and the scheme for which the Corporation now asked for a loan had been sanctioned by them. The site of the proposed works belonged to the Corporation. In 1896, in consequence of pressure by the Board of Trade, the Corporation had practically entered into an agreement with a private company (Messrs. Thomas King and Co.) to assign their powers under the provisional order, but owing to the opposition of the ratepayers the Corporation decided to retain the order and themselves erect electricity works. The present method of dealing with refuse was unsatisfactory, and the Council wished to combine a dust destructor with electric lighting. After considerable investigation, a local firm of engineers was consulted as to the electric light works, and for the dust destructor the Horsfall Co. was approached. Originally the Local Government Board were asked to sanction £30,000, but the area in which it was proposed to lay electric lighting mains had been enlarged, and it was finally resolved to ask for £40,000, in order to carry out the whole of the work. Dust destructors were erected in a number of manufacturing districts, and no complaint had ever been made against the Horsfall destructor. Applications for, or promises to take electric current equal to 6,600 8 c.p. lamps had already been received, and the equivalent of 2,358 8 c.p. would be required for public lighting, but they anticipated applications for a total of 16,060 8 c.p. lamps. There would be 32 arcs of 1,000 c.p. for the main thoroughfares, and 119 32 c.p. incandescent lamps for the outlying streets. The net profit was estimated at £1,015. 11s. 9d., but there would be a loss of over £460 on the destructor, which would reduce the annual profit on the whole scheme to £543. 15s. 9d. The cost of the electric lighting scheme (according to tenders provisionally accepted) would be £33,598. 6s. 6d., and the dust destructor £6,431. 15s. 6d. Mr. W. A. Stevens (Messrs. Stevens and Barker, consulting engineers) gave technical details. He said the charge for current would be 7d. per unit for the first hour and 2d. after. His scheme was a continuous-current, three-wire system one, the distributing mains being fed at five points. His firm had carried out work for the Chatham and Rochester municipalities. He had been engaged in electrical work for over ten years, and was an associate of the Institute of Electrical Engineers. He had no experience in central station work. He had not based his scheme on that prepared by Messrs. Kincaid, Waller and Manville. He was aware of that firm's report, but did not copy their figures. In his estimate he put the revenue at £5,237, and the capital at £26,000. He knew of no other instance, except Tunbridge Wells, where they had made such a revenue for the outlay. He expected to make money at Maidstone in the first year or two. The life of the plant would be about 20 years if properly repaired, and in his estimate he had allowed for depreciation. He estimated the profit on the whole scheme to be £543. 11s. 9d. for the first year's working. After further evidence had been given the destructor portion of the scheme was abandoned.

Manchester.—Mr. W. H. Vaudrey has been elected chairman of the Telephone committee in place of Ald. Southern, resigned. The committee resolved to ask for a reply from the National Telephone Co. to the inquiry as to the terms the company are prepared to sell their Manchester undertaking to the Corporation.

Mile End (London).—The Guardians have discussed a report by a special committee on the electric lighting arrangements at the workhouse, in which it was stated that their consulting engineer (Capt. J. M. Knight) had informed them that the engines, boilers, batteries and the electrical installation generally at the workhouse were unsuitable to their requirements, and the total cost of remedying the defects is put at £6,000. The committee state that the labour bill in the electrical department has been about doubled since 1895, and the coal bill quadrupled, and they recommend a rearrangement of the engineering staff. The report has been referred back.

Municipal Telephony.—On Tuesday Dover Corporation considered a report recommending the erection of a municipal telephone exchange. The report was based on the assumption that there would be 300 subscribers' and 20 public telephone lines complete at £16 each (£5,120); 150 partially completed lines at £8, £1,200; total, £6,320. To put the telephone on a remunerative basis, it was estimated that £5 10s. per line should be charged for subscribers requiring an unlimited number of calls; and £3 10s. per annum with a toll of 1d per call for others. With the estimated number of subscribers, a net profit of £125 a year would be earned. The discussion was adjourned.

The Leicester Telephone committee recommend the Council to authorise them to ascertain the probable number of customers for a municipal telephone service, and to collect further information as to the advisability of erecting an exchange. The committee have retained the services of Mr. A. R. Bennett as consulting telephone engineer. Notice has been given to the National Co. to terminate the agreement as to underground wayleaves on June 24. The committee report that there are only about 1,150 subscribers, whilst if telephone were used to the same extent as in some continental towns where there are cheaper rates the number would probably be more than 6,000. Without a competitive service they urge there is no likelihood of the existing rates being reduced. They are advised and are of opinion that a remunerative municipal service might be given on the following terms: £6. 6s. per annum for an unlimited number of calls, or alternatively £3. 10s. per annum, and 1d. a call for each call up to a mile from the exchange, and for any excess of distance beyond a mile a small extra charge. These rates are put to cover cost of installation, maintenance, and Government royalties, and will secure communication with all parts of the Leicester telephone area. The committee are of opinion that before considering the question of applying for a licence it should be ascertained what amount of support from the public could be relied upon, and a canvass for subscribers is to be undertaken. The committee do not recommend the Council to apply for a licence unless 1,000 subscribers are obtained as a start.

The Tunbridge Wells Corporation are having a specification for a municipal telephone exchange prepared.

Newcastle-on-Tyne.—The Newcastle-on-Tyne City Lunatic Asylum at Coxlodge is lighted throughout electrically. The lighting contract was carried out by the Corlett Electrical Engineering Co., and the contract for telephones, electric bells, electric clocks, &c., by Messrs. John Mills and Sons. The asylum is also ventilated by electrically-propelled fans, and electricity is employed for working the laundry machinery.

Nuneaton.—The District Council have called in Mr. W. C. C. Hawtayne to report upon the question of purchasing the undertaking of the Nuneaton Electric Supply Co.

Paisley.—From 30th inst. the charge for electric current for lighting purposes will be 6d. per unit for the first hour's maximum demand and 2d. afterwards, in place of 7d. and 3d. as at present, and that for power and heating 2½d. per unit. The Electric Light committee are considering the advisability of adopting a uniform rate for lighting.

Reigate.—The charge for electric current has been fixed at 7d. per unit for the first hour's maximum demand and 4d. after, while a uniform charge of 3d. per unit is to be charged for power.

St. Anne's-on-Sea.—An inquiry was held last week into the application of the Council for permission to change the site of their proposed electricity works. The electrical engineer (Mr. P. J. S. Tiddeman) said the new site was well suited for an electric lighting station. It was not so close to the town as the old site, and would cost a little more for feeders and cables. There was no opposition.

Skipton.—The local ratepayers are agitating in favour of the erection of electricity works.

Southampton.—The town section of the new municipal electric tramways has been officially inspected by the Board of Trade, and the line were opened for traffic on Tuesday.

Southend.—The Town Council has discussed a proposal to so extend the electric tramway scheme as to include the High-street in the new routes. The proposal was defeated.

Telegraphs and Railways in Turkey.—The Vienna correspondent of *The Times* states that active measures have already been taken for carrying into effect the Sultan's Iradé respecting the construction of a railway from Damascus to Mecca, and of a telegraph line from Selt, near Damascus, to the Hedjaz.

Telegraphs in Afghanistan.—Lord George Hamilton recently stated in the House of Commons, in reply to Mr. Maclean, that the Government of India had on several occasions advised his Highness the Ameer to give attention to the construction of telegraphs and railways, but the Ameer had never shown any desire for the extension of railways or telegraphs in Afghanistan.

Toronto.—According to a New York journal the municipality of Toronto is making arrangements with the Toronto Street Railway Co. to establish a system of electric railways, embracing the country around Toronto between Brantford, Peterboro', and Georgian Bay, a radius of nearly 100 miles, and a total track mileage of 354 miles. The expenditure involved for track and permanent way has been estimated at £570,000, and the total expenditure at £800,000.

Trieste (Austria).—The existing horse tramways in this city are about to be superseded by electric lines on the overhead trolley system. Part of the city is now lighted electrically.

War Office Contracts.—In the course of his evidence before the Parliamentary Committee on War Office contracts, Mr. Major, director of army contracts, was reported to have stated that Messrs. J. Stiff and Sons, of the London Pottery, Lambeth, S.E., had been struck off the list of War Office contractors for offences under the Corrupt Practices Act. Mr. Major's evidence was, we understand, erroneously reported. It appears that a young member of Messrs. Stiff's firm went to Woolwich and looked at some stores that were under inspection and had been rejected. In the course of his visit he offered small gratuities to the foreman and viewer, which, he said, he did for assistance they rendered him, and in ignorance, as he thought it was in the ordinary course of business, when people had done a service, to give them a little remuneration. This act was, however, held to be sufficient to justify a suspension for 12 months. We are asked to say that the War Office have not cancelled existing contracts with Messrs. Stiff and Sons, under which that firm will be supplying goods to the department until December next.

West Ham.—A scheme for wiring consumers' premises on the easy wiring system has been devised by the borough electrical engineer (Mr. J. K. Bock). The Corporation has obtained powers to borrow £10,000 for free wiring. An agreement is to be made with contractors to wire premises in the borough at the rate of 13s. per lamp (shop and factory), and 15s. (private house), and the consumer is charged 1s. 6½d. and 1s. 9½d. per annum respectively for repayment of capital and interest. Ten years are allowed in which to pay for the installation.

Wireless Telegraphy.—In the House of Commons on Monday, Mr. Hanbury, in reply to Sir John Leng, said there was no information at the Post Office as to the extent to which the Marconi system of wireless telegraphy had been adopted in America, France, Germany, or other countries, but, of course, a licence would be granted in this country if suitable terms could be arranged.

Wolverhampton.—The extensive new works of Messrs. Chubb and Sons are lighted electrically. Electric driving has also been adopted, current being taken from the town mains.

Electro-Harmonic Society.—The annual general meeting of this society was held on Tuesday. The report of the hon. sec., Mr. C. E. Grove, stated that during the past season 36 members were elected and 25 resigned, five members were lost by death, and nine owing to non-notification of address, while 10 have been struck off the register for non-payment of subscription. The membership now numbers 278, and 20 proposals are before the committee. It is satisfactory to learn that the society's concerts next season will be held in the old room of the St. James's Hall Restaurant. A suggestion is before the committee that Wednesday evening be substituted for Friday evening for the holding of the concerts, and the views of members are invited upon this point. The receipts (including £34 3s. 1d from 1899-1900) realised £205s. 8s. 1d., leaving a balance over expenditure of £25. 1s. 8d. The surplus assets to May 19 amounted to £28s. 16s. 2d.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

TENDERS INVITED.

Shoreditch (London) Vestry require tenders for the supply of eight dry-back marine-type boilers, or eight water-tube boilers, with automatic stokers, and sundry ironwork for their new generating station at Whiston-street. Specification may be obtained at the office of the electrical engineer (Mr. C. Newton Russell), Electric Light

Digitized by Google

Station, Coronet-street, Hoxton, N., and a copy of the specification may be inspected (but not obtained) at the offices of the consulting engineers (Messrs. Kincaid, Waller and Manville), 29, Great George-street, Westminster. Tenders to Dr. H. Mansfield Robinson, vestry clerk and solicitor, Town Hall, Old-street, E.C., before noon on 19th inst. An advertisement contains further particulars.

Durban (Natal) Corporation invite tenders for the supply, delivery and erection of the overhead equipment for about 16 miles of equivalent single track, including poles, overhead trolley wire, distribution boxes, &c.; 22 double-deck motor cars complete; electricity generating plant, including three 250 kw. direct-coupled generators, boilers, condensers, cooling tower, switchboard, &c. Tenders in duplicate to the agents (Messrs. Webster, Steel and Co.), 5, East India-avenue, Leadenhall-street, London, E.C., by June 29, or to the town clerk of Durban by mail delivery on or about Monday, July 23.

Bradford Corporation require tenders for the supply and erection of a switchboard, or for alterations to existing switchboard, at the Valley-road electricity works. Specification can be obtained from the city electrical engineer (Mr. R A. Chattock), Town Hall, and tenders must be sent to the town clerk (Mr. Frederick Stevens), by June 14. An advertisement contains additional particulars.

Dudley Corporation invite proposals for wiring premises in the district on the free or easy wiring system. Particulars are set out in an advertisement, and specification, &c., may be obtained from the consulting engineer (Mr. Reginald P. Wilson), 66, Victoria-street, Westminster, S.W. Tenders to town clerk (Mr. H. C. Brettell), Town Hall, Dudley, by 15th inst.

The Vestry of St. Mary Magdalene *Bermondsey* (London), require tenders for the supply and laying of insulated electric mains, conduits, junction boxes, &c. Specifications, &c., can be obtained on and after June 5 at the Town Hall, Spa-road, S.E., and can be inspected at (but not obtained from) the offices of the engineers, Messrs. Kincaid, Waller and Manville, 29, Gt. George-street, Westminster. Tenders to Mr. Fred Ryall, vestry clerk, Town Hall, Bermondsey, before noon of June 18. An advertisement gives further particulars.

Glasgow Corporation require tenders for outside coal storage and steel structure for coal handling, and locomotive travelling cranes for outside coal handling, for their Pinkston power station. Specification can be obtained from the general manager of the tramways department (Mr. John Young), 88, Renfield-street, and tenders must be lodged with the town clerk (Sir J. D. Marwick) by 5 p.m. on 21st inst. An advertisement gives further particulars

Glasgow Corporation also invite tenders for the supply of two sets of switchboards and instruments for 4,000 amperes each. Tenders to town clerk (Sir J. D. Marwick) before 10 a.m., June 12.

The Electric Lighting committee of the *St. Mary, Newington* (London) Vestry require tenders for the supply and laying of insulated electric mains, conduits, junction boxes, &c. An advertisement contains additional particulars, and specifications may be obtained at the offices of the consulting engineers (Messrs. Kincaid, Waller and Manville), 29, Great George-street, Westminster, S.W. Tenders to vestry clerk (Mr. L. J. Dunham), Vestry Hall, Walworth, S.E., by noon 15th inst.

Stockport Gas and Electricity committee require tenders for two water-tube boilers for their Millgate electricity station. An advertisement contains further particulars, and specifications, &c., may be obtained from the engineer (Mr. S. Meunier), Gas and Electricity Offices, Portwood. Tenders to chairman of committee by 13th inst.

London County Council's Asylums committee invite tenders for the installation of electric lighting and power (except generating plant) and the installation of telephones, tell-tale clocks, fire alarms and call bells at the Horton Asylum, near Epsom, Surrey. Tenders to the committee, 6, Waterloo-place, S.W., by 10 a.m, June 16.

Blackpool Corporation invite tenders for the electrical equipment of 15 single truck tramcars. An advertisement contains further particulars, and tenders must be sent to the borough electrical engineer (Mr. Robt. C. Quin) by 18th inst.

The Provost, Magistrates, and Commissioners of the burgh of *Partick* invite tenders for the construction, supply, and erection of a dust destructor, with furnaces, flues, water-tube boilers, economiser, fans, and forced-draught furnaces. Tenders to Mr. Jas. Donaldson, town clerk, 97, West Regent-street, Glasgow, by noon of June 8.

South London Electric Supply Corporation invite tenders for a complete installation of 3,000 lights on the premises of 500 consumers in any part of the company's area of supply, and also for the installation of two arc lights on the premises of any consumer in the same area. Tenders by June 2.

Altrincham Electric Supply (Ltd.) require tenders for erecting a chimney shaft, foundations, &c. Tenders to chief engineer by 9th inst.

Tenders are invited for the public lighting of *Larne* for three years from August 1. Tenders to clerk, Town Hall, Larne, by 18th inst.

Hackney Electric Lighting committee require tenders for the erection of electricity station buildings. Tenders to clerk by 13th inst.

Salford Tramways committee require fish and sole plate bolts. Tenders by 5th inst.

Sutton Coldfield Corporation invite tenders for the supply and erection of electricity generating plant. Tenders to the town clerk (Mr. Holbeche) before noon of June 21.

Manchester Tramways committee invite tenders for the overhead equipment of three tramway routes. Tenders to chairman by June 9.

Bootle Corporation invite tenders for supply and laying of underground electric cables, erection of arc lamps, and the supply of mechanical stokers. Tenders to town clerk (Mr. J. Henry Farmer) before June 16.

Chester Corporation invite tenders for steam, exhaust, feed-suction, condensing water pipes and valves. Tenders to town clerk (Mr. S. Smith) by 10 a.m. June 4.

North Eastern Railway Co. invite tenders for telegraph apparatus, telegraph wire, and line stores. Tenders to secretary (Mr. C. N. Wilkinson), York, by June 4.

St. Pancras (London) Vestry invite tenders for re-arranging and making additions to bare copper strip conductors. Tenders to vestry clerk (Mr. C. H. F. Barrett) by noon, June 7.

Sleaford Council invite tenders for electric lighting plant. Tenders to clerk by June 12.

Ealing District Council invite tenders for a storage battery and a steam alternator. Tenders to clerk by June 11.

Fulham (London) Vestry require tenders for the wiring of their electric lighting works. Tenders to Mr. W. J. H. Denselow, clerk, Town Hall, Walham Green, S.W., by June 4.

Bridgwater Town Council invite tenders for the supply and erection of electricity generating plant. Tenders to town clerk (Mr. W. T. Baker) before 3 p.m. on June 7th.

Luton Town Council require tenders for the erection of electricity station buildings. Tenders by June 18.

Wallasey District Council invite tenders for the maintenance of the electric installations on their ferry steamers. Tenders to the Clerk by 12th inst.

TENDERS RECEIVED AND ACCEPTED.

The following tenders for electricity generating plant are recommended for acceptance by a committee of the Melbourne City Council:—

Babcock and Wilcox (boilers and economisers)	£6,604 0 0
Thomas Parker, Ltd. (engines, dynamos, boosters and switchboard)	22,367 0 0
British Insulated Wire Co. (cables and joint boxes)	27,348 5 4
Tudor Accumulator Co. (accumulators)	3,529 0 0

At the weekly meeting of the London County Council on Tuesday the Fire Brigade committee reported that the following tenders had been received:—For wiring and fitting of electric light at the new Islington fire station:

Barlow Bros. and Co. (*accepted*)	£277 0	Private Wire and Telephone Installation Co.	£428 0
F. A. Glover and Co.	296 3	A. H. Wood	450 0
F. J. Coleby	335 0		

For wiring and fitting of the Whitechapel station:

F. A. Glover and Co. (*accepted*)	£282 6	A. H. Wood	£430 0
F. J. Coleby	331 15	Private Wire and Telephone Installation Co.	445 0

Devonport Corporation are recommended to accept the tender of the Callender Co. for the supply of electric light and traction feeders, distributors, boxes, &c, for £12,433. 6s 10d. The tenders were:—

Callender Co.	£12,433 6 10	Siemens Bros. & Co.	12,690 3 5
Western Electric Co.	14,149 18 8	W. T. Henley's Co.	£12,555 6 4
W. T. Glover & Co.	12,963 0 0	St. Helens Cable Co.	12,379 1 5
Brit. Insul. Wire Co.	12,875 16 0		

Hoylake and West Kirby Council have accepted the amended tender (the lowest) of Mr. J. Merritt, Birkenhead, for the erection of an electric lighting station for £6,500.

Leicester Corporation have accepted the tender of the Brush Co. for the supply of two 1,000 kw. inductor alternators (with Hick-Hargreaves horizontal engines) at £22,837.

Wimbledon District Council have accepted the tender of Messrs. Foote and Milne for wiring and fitting the isolation hospital for the electric light. Twenty-three tenders were received.

The Rhyl Council have accepted tenders, amounting to £16,543, in connection with the electric lighting scheme, and have decided to apply for sanction to borrow £19,000.

The tender of Mr. C. Dennes has been accepted for the erection of the Heywood electricity station buildings.

Digitized by Google

The following tenders have been received by the Rhyl District Council for the supply of electricity generating plant.

Section A.—(Boilers.)

Babcock & Wilcox (*accepted*)	£2,013 10	Geo. Hill & Co.	£2,350 0
Stirling Boiler Co.	2,490 0	R. W. Blackwell & Co.	2,058 0
		Crompton & Co.	2,058 0

Section B.—(Engines, Dynamos, Boosters, &c.)

Lancashire Dynamo Co. (*accepted*) (Alley-Maclellan engine)	£5,759
Ditto (Willans)	6,204
Ditto (Browett-Lindley)	5,551
Ditto (Reavell)	5,359
Ditto (Willans)	7,470
Ditto (Alley-Maclellan triple)	7,453
Lowdon Bros. and Co. (Willans triple)	7,677
Ditto (Belliss triple)	6,869
Ditto (Willans compound)	6,677
Ditto Bros. (Belliss compound)	6,569
Ditto (Browett-Lindley)	5,809
Ditto (Reavell)	5,682
Siemens Bros. and Co. (Willans triple)	8,249
Ditto (Belliss)	7,264
Ditto (Willans compound)	7,239
Ditto (Belliss triple)	7,204
Ditto Bros. and Co. (Browett-Lindley)	6,444
Crompton and Co. (Alley-Maclellan triple)	7,880
Ditto (Belliss triple)	6,903
Ditto (Willans)	6,849
Ditto (Belliss)	6,806
Ditto and Co. (Davey-Paxman)	6,385
Ditto (Allen)	5,519
George Hill and Co. (Browett-Lindley)	6,210
S. H. Heywood (Alley-Maclellan triple)	7,811
Ditto (Alley-Maclellan)	6,156
Thames Ironworks Co. (Willans triple)	7,239
Ditto (Willans)	6,112
Ditto (Reavell)	5,268
Ditto (Allen)	5,133
John Fowler and Co. (Reavell)	6,042
British Westinghouse Co. (Willans triple)	7,680
Ditto (Allen)	5,560
Ditto (Belliss triple)	7,040
Ditto (Belliss compound)	6,650
Ditto (Willans compound)	6,620
Ditto (Browett-Lindley)	5,995
British Schuckert Co. (Willans triple)	7,702
Ditto (Browett-Lindley)	5,992
Ditto (Reavell)	5,762
Johnson and Phillips (Willans triple)	8,090
Ditto (Willans)	5,870
Electric Construction Co. (Willans triple)	7,931
Ditto (Willans)	6,852
Ditto (Willans compound)	6,763
Ditto (Reavell)	5,832
W. H. Allen, Son and Co. (own)	5,771
Electrical Co.	5,641
General Electric Co. (Willans triple)	7,768
Ditto (Belliss triple)	6,925
Ditto (Willans compound)	6,702
Ditto (Reavell)	5,572
C. A. Parsons and Co. (Parsons turbine)	5,017
Ashton, Frost and Co. (Willans triple)	8,525
Brush Co. (Universal)	8,314
T. Scott Anderson (Willans triple)	7,935
Frank Suter and Co. (Willans triple)	7,205
Clayton Engineering Co. (Alley-Maclellan)	6,784
E. Scott and Mountain (own)	6,750

Section C.—(Switchboard.)

Clayton Engineering Co. (*accepted*)	£590 0	Crompton & Co.	£902 0
Siemens Bros. & Co.	1242 0	Johnson & Phillips	900 0
Electric Construction Co.	1085 0	Ashton, Frost & Co.	896 0
Mechan & Sons	999 0	Veritys	851 0
Hodgson Wright	991 0	Lewis, Bayliss & Co.	782 0
Dorman & Smith	930 0	General Electric Co.	765 10
John Fowler & Co.	920 0	Brook, Hirst & Co.	745 0
		Lowdon Bros. & Co.	599 0

Section D.—(Arc Lamps, Underground Mains, Street Work, &c.)

Western Electric Co. (*accepted*)	£5,911 11	Callender Co.	£6,797 0
Telegraph Mfg. Co.	9,233 0	Oliver and Co.	6,758 0
Johnson and Phillips	8,181 0	Ditto	6,289 0
W. T. Henley's Co.	7,464 0	British Insulated Wire Co.	6,545 0
W. T. Glover and Co.	7,455 0	W. F. Dennis and Co.	6,184 0
Siemens Bros. and Co.	7,013 0	St. Helens Cable Co,	6,125 0

Section F.—(Accumulators.)

Dutilh-Smith, McMillan and Co. (Marquand accumulator) (*accepted*)	£1,304	D.P. Battery Co.	£1,446
T. Scott Anderson	1,900	Johnson and Phillips (Hart accumulator)	1,430
S. H. Heywood	1,577	Elec. Power Storage Co.	1,425
Chloride Elec. Storage Synd.	1,500	Tudor Accumulator Co.	1,395
		Hart Accumulator Co.	1,361

Section G.—(Crane.)

Marshall, Fleming and Jack (*accepted*)	£145	Stocks and Co.	£167
Iales, Ltd.	220	Carrick and Ritchie	159
		Jas. Carrick and Sons	152

APPOINTMENTS VACANT AND FILLED.

The post of senior demonstrator in the department of electrical engineering and applied physics at the City and Guilds Technical College, Finsbury, will be vacant at the close of the present session. The salary is £150, rising to £200. Applications for the post have to be addressed, in the first instance, to the principal of the college, Leonard-street, Finsbury, London, E.C., by June 29. An advertisement gives some further particulars.

Southport Corporation are open to receive applications for the following appointments in connection with their new tramway scheme :—(1) Depot superintendent, wages £2 per week ; (2) Inpector, wages 35s. per week and uniform. Applications to Mr. J. Ernest Jarratt, town clerk, Town Hall, Southport, by June 6. Further particulars will be found in an advertisement.

Birmingham Corporation require two lecturers for the electrical and engineering departments of the municipal technical school in September next. An advertisement contains further particulars, and applications must be sent to the secretary (Mr. Geo. Miller), Suffolk-street, by 30th inst.

The Council of the Municipal Electrical Association require a secretary to act under the direction of the honorary secretary. Applications to the president (Mr. A. B. Mountain, borough electrical engineer, Huddersfield), by 14th inst. An advertisement contains additional particulars.

The governing body of the Battersea Polytechnic require an assistant lecturer in physics and electrical engineering from September next. Particulars from secretary, Battersea Polytechnic, S.W. See advertisement.

Hull Electric Lighting committee require an assistant electrical engineer at their Sculcoates lane generating station. An advertisement contains further particulars, and applications must be sent to the city electrical engineer (Mr. A. S. Barnard), Dagger-lane, Hull, by noon of 7th inst.

Johnson and Phillips' Electric Cable Works, Old Charlton, Kent require a draughtsman and a shop foreman for their additional lead-covering cable factories. Particulars will be found in an advertisement on another page.

Buxton District Council require an assistant electrical engineer. An advertisement gives further particulars, and applications must be sent to the chief engineer (Mr. Edward Calvert) by noon of 12th inst. There is also a vacancy for a premium pupil at the works.

An assistant engineer and draughtsman is required for the Ohm Electric Works, Northallerton. See advertisement.

Pembroke (Co. Dublin) Township Commissioners require a fitter-driver, and a cable jointer for their electricity works. Applications to the clerk (Mr. J. C. Manly), Town Hall, Ballsbridge, Co. Dublin. See advertisement.

A principal is required for Wandsworth Technical Institute at a commencing salary of £400 per annum. Applications to Mr. A. R Gridley, 4, Galveston-road, Putney, by June 18.

Two university lectureships in experimental physics are vacant at the Cambridge University. The appointments are for five years, and the stipend £50 a year. Applications to Vice-Chancellor by June 2.

An assistant lecturer and demonstrator in electrical engineering is required for the University College of North Wales, Bangor. Applications to Mr. J. Lloyd, M.A., by June 9.

A head-master is required for the Industrial School, Lucknow, India. Forms of application and further particulars from Director-General of Stores, India Office, Whitehall, London, S.W.

Jandus Electric Co., Hartham Works, Hartham-road, Holloway, London, N, require an assistant tester. See advertisement.

Brighton Corporation require an engineer in connection with their proposed electric tramway scheme. Applications to town clerk (Mr. F. J. Tillstone), Town Hall, Brighton, before 10 a.m. on June 8.

The Belfast Electric committee require an engineer-in-charge and a junior assistant for their electricity works. Applications to Mr. Victor A. H. McCowen by June 5.

There is a vacancy for an assistant superintendent in the telegraph department of the Government of India. Applications to Secretary, Public Works Department, India Office, London, S.W., by June 30.

An assistant manager is required for an electric incandescent lamp factory near London. See advertisement.

Mr. W. M. Heller, B.Sc., head master of the day science school in connection with the Birmingham Technical School, has been appointed by the National Board of Education of Ireland organiser of science instruction in Irish schools, and will take up his new duties in the autumn.

Mr. Charles Dudding, an assistant engineer at the Yarmouth electricity works, has been appointed assistant electrical engineer to the Hastings Corporation at a salary of £120 per annum. There were 95 applications.

Digitized by Google

Mr. George E. Heath, of Dundee, has been appointed second assistant at the York electricity works.

Mr. E. Taylor, assistant engineer at the Kelham Island Tramway power station, Sheffield, has been appointed chief assistant engineer for the Birkenhead electric tramways.

BUSINESS NOTICES.

Messrs. R. W. Blackwell and Co. (Ltd.), 39, Victoria-street, London, S.W., are about moving their stores and offices to new premises in the City-road, E.C., adjoining Wesley's Chapel.

The Electrical Engineer Institute of Correspondence Instruction has removed from 120-122, Liberty-street to 240-242, West 23rd-street, New York, U.S.A., as, owing to the rapid growth of the Institute, the old quarters some time ago became inadequate to meet the demands for space. The Institute has, we are informed, a vast number of students located all over Great Britain and the Colonies as well as in the Western Hemisphere, and carries on its work in nearly every civilised country. Catalogues, giving full information regarding the courses of instruction, will be supplied on application.

Messrs. W. Scholes, J. Whitehead and J. E. Shore, electrical and mechanical engineers (trading as Scholes and Son, at 85, Corporation-street, Manchester, and as J. Whitehead and Son, at 10, Rochdale-road, Middleton), have dissolved partnership. Debts by Mr. Scholes, who continues under the style of Scholes and Son.

Mr. J. Burns, of 15, Long-lane, is removing to 76, Little Britain, London, E.C., and communications should be sent to the new address from to-day.

BANKRUPTCIES, LIQUIDATIONS, &c.

Claims against M. H. Barber (trading as Donnison, Barber and Co.), electrical engineer and contractor, 10, Corporation-street, Manchester, must be sent by June 14 to the trustee, Mr. J. Wilson, 37, Brown-street, Manchester.

The discharge of W. P. O'Reilly, manufacturing electrician, 397, Edgware-road, and lately trading at 397 and 399, Edgware-road, and 124, Old Broad-street, London, has been suspended for three years.

Business for Disposal.—An electrical engineering business is advertised for sale in another column. The works are conveniently situated within 10 minutes of London.

For Sale.—A leasehold factory and about four acres of land, situated in Essex, and about 12 miles from London, together with tools and plant and surplus stock, are offered for sale by private tender. Tenders by June 19 to Messrs. Sydney Lee, and Co. (Ltd.) 9, Furnival-street, Holborn, London, E.C., from whom forms of tender and conditions of sale may be obtained.

An advertisement elsewhere contains particulars of an important Planté process for forming accumulator plates, the foreign rights of which are for sale.

Gas and Oil Engines.—The Dudbridge Ironworks (Ltd.), Stroud, have just issued a neat pamphlet describing their make of gas and oil engines. The "Dudbridge" gas engine for electric lighting, of which particulars are given, is made in sizes from 2 to 30 B.H.P.

Steam Specialities.—An interesting and useful catalogue of steam users' requirements manufactured by the British Steam Specialities (Ltd.), of Fleet street, Leicester, is just issued, and contains numerous illustrations and fairly complete particulars relating to a large variety of these specialities, including reducing valves, extractors, governors, steam traps, damper regulators, temperature controllers, &c. The catalogue is well got up, and can be obtained on application to the company.

Electric Motor Vehicles.—Messrs. Shippey Brothers have now ready an illustrated pamphlet describing various types of electric motor vehicles manufactured on the "Still" system, for which they are agents in this country.

"Phono" Electric Wire.—This wire, made by the Bridgeport Brass Co., of New York, is being introduced into this country by Messrs. Maguire and Baucus. According to a neat book of tables, &c., which has been sent us, it appears that the wire, made of a special alloy, has a specific resistance somewhat more than twice that of copper, but that its mechanical properties are far superior to those of hard-drawn copper wire. An interesting table is given showing the effect, on the tensile strength, of removing the surface from hard-drawn copper wire, and a similar table for the "Phono" electric wire.

Machine Tool Catalogue.—Messrs. George Richards and Co. (Ltd.), of Broadheath, Manchester, have issued an abridged illustrated catalogue of machine tools, pattern-making machinery, &c., in which a number of well-made, highly-finished planing, shaping, scarfing, drilling, boring, sawing, facing, and turning machines are described. The catalogue further illustrates several types of single and duplex vertical and horizontal air compressors and a variety of pulleys, hangers, suspension brackets, couplings, and bearings, for which Messrs. Richards and Co. have an established reputation.

Exports of Electrical Apparatus and Material.—The following list gives official particulars of the exports of British manufactured electrical apparatus and material (including telegraph and telephone wire and material, but not including electrical instruments or machines, which are not separately specified) from May 23 to May 29, with the ports of destination:—

Africa—Alexandria, £173; Cape Town, £283; Durban, £74; East London, £94; Port Elizabeth, £100. *Argentina*—Buenos Ayres, £393 (telegraph wire). *Australasia*—Lyttleton, £75; Sydney, £140. *Brazil*—Rio Janeiro, £54. *Ceylon*—Colombo, £110. *Chili*—Valparaiso, £75. *China*—Hankow, £2); Shanghai, £815 (including £118 old telegraph wire) and 25 tons old telegraph wire). *Denmark*—Copenhagen, £279 (telegraph wire). *France*—Boulogne, £20; Rouen, £76. *Germany*—Hamburg, £400 (telegraph material). *Gibraltar*, £135 (including £25 telegraph material). *Holland*—Amsterdam, £155. *Hong Kong*, £60 *India*—Bombay, £184 (including £49 telegraph material); Calcutta £490. *Japan*—Hiogo, £90; Nagasaki, £4,700 (telegraph cable); Yokoska £3,078. *Russia*—St. Petersburg, £587 (including £157 telegraph cable). *Spain*—Barcelona, £340 (telegraph material). *Straits Settlements*—Singapore, £564 (including £482 telegraph material). *Sweden*—Gothenburg, £23 (telegraph cable); Stockholm, £428 (telegraph wire). Total £14,575, against £13,706 for six days last year (May 25 to May 30).

COMPANIES' MEETINGS AND REPORTS.

West India and Panama Telegraph Co. (Ltd.)

The forty-sixth ordinary general meeting of the members of this company was held at Winchester House, Old Broad-street, on Wednesday, May 30, 1900, under the presidency of Mr. WILLIAM ANDREWS.

The MANAGER and SECRETARY (Mr. R. T. Brown) read the notice convening the meeting.

The CHAIRMAN: Gentlemen, I am afraid that the remarks we shall have to make to-day will throw a very disagreeable light on the present position of the British West India islands. If there is any truth in the close connection which is said to subsist between the activity of the telegraph and the activity of trade and commerce of given districts, the story we have to tell to-day will not be a cheerful one. For instance, the receipts this last half-year, to Dec. 31, were £22,643 as against £51,937 in the corresponding period of the previous year, showing a decrease of £29,294. That is not one of the features that we shall have to dwell upon to-day, because the large receipt in the December half of 1898 was quite abnormal; it was, as you know, owing to the Spanish-American war, which altogether, so to say, revolutionised our receipts in 1898. A more proper comparison would be made with the last half of 1897; but even here there was a reduction shown in the comparative revenues of £9,584. There is no doubt that our present very low receipts are owing to the reductions in the rates which were made in January, 1898, and February, 1899, coupled with a paucity of business. Further reduced subsidies only account for a loss this half-year of £356, and there is a loss of about £500 owing to the interruption of the Colon cable. Therefore in fact, the failure of low rates to stimulate business, owing to the deplorable sluggishness of trade and commerce in the West India Islands, has alone caused the diminished revenues. There is no fault to be found with the expenses, which amounted in the past six months to £21,433, against £24,443 for the corresponding period of the previous year, showing a decrease of £3,011. Practically, our expenses are at about their lowest ebb, and this decrease is owing to an exceptional state of things. For instance, in the repair of cables there is a reduction of £611; that is a thing which we cannot control. The expenses of the London office were £265 less; that is a matter we can control, but it compares with a period when extra work had to be done. The same may be said of the stations abroad, at which there was a decrease in the expenses of £857. There is also a less amount by £1,031 for depreciation of ships. Those figures make a decrease of £3,011, and the only increase deductable from that is £265 in maintenance of land lines. The shareholders have doubtless observed that last Monday week, in the High Court, Mr. Justice Farwell thought that the plaintiffs were entitled to succeed in the action brought by the Cuba Co. against this company to determine the construction of the agreement between the companies, but a declaration had to be settled by counsel and mentioned at a later date; and then it was understood that an appeal would have to be made. It would therefore be very improper for me at this stage of the proceedings to make any observation on the case, except to say that practically the matter has gone against us in the first Court, and we shall now have to do our best in the Court above. A feature that is disappointing in our company again is that the Legislature of the colony of Barbados reduced the company's subsidy as from Jan. 1, 1900, by £1,000 per annum. As you know, these colonies have been continually reducing the subsidies we received from them, and in the present case the reduction was made despite the opinion of the Barbados Government. The consequence of that and of other reductions is that the current subsidies now amount to only £13,100 per annum, as against £24,400 in the year 1886. Of course, we cannot but see that if the prosperity of the islands is so interfered with, as it has been and is, by want of trade and commerce, it is not an unnatural thing that they should try and save money by reducing their subsidies. It is an unpleasant thing for us, but it is not an unnatural step for the colonies to take. We do our best to maintain the subsidies, but unfortunately, unless something can be done to keep up these islands, I do not know how that sort of nibbling of the subsidies may end; and when we consider that we have 4,639 miles of cable and 194 miles of land lines to support, and that the whole of the subsidies we get now is only £13,100 a year, besides an insufficient revenue from other sources, you will not be surprised at the present state of the accounts. Another extraordinary fact is that the number of words which

Digitized by Google

were exchanged in 1877, on the introduction of the word rate, intercolonially—that is, between the islands of the West Indies—amounted to 533,639, and since then, notwithstanding fluctuations of rates—always, by-the-bye, in the direction of lower rates—and, notwithstanding the recent large reductions, the number of words in 1899 had actually dropped to 163,714. That is about 3½ times less than the number of words exchanged between the islands when the word rate was introduced. Of course, we do the best we can for your interests, but we cannot increase the traffic of the West Indies. We cannot give the West Indies trade and commerce which they do not seem at present to possess. Now, reverting to the traffic, the words transmitted in 1899—after the large reductions that have been made—as compared with the corresponding period of 1897 (again omitting the war year)—do show an increase over the entire system of some 34,700 words, principally, I may say, at foreign stations. But here again, unfortunately, there is a decrease at the British stations in intercolonial traffic of 2,016 words. In fact, as we can see, the British West Indies are getting decidedly the worst of it. The net increase, I need hardly tell you, is totally inadequate to compensate us for the great reductions that were made in the rates. It seems clear to me—it is a matter of personal opinion, perhaps—that without extraneous aid the measure of the traffic must be the measure of the tariff. If, for instance, the traffic only measured 100 messages per annum between given points, it is clear that that 100 messages must be tariffed so as to cover all the charges and the payment of reasonable dividends for the employment of the capital of any company, whatever it might be. That seems to me only reasonable; in fact, I do not see how one can get away from it. It is no use talking about low rates increasing business, which is the general pabulum one is favoured with. Of course, in a certain sense an increase of business, an additional number of words, may be sent, as we have seen in our case, but it is inadequate—inadequate to the necessities of the case. I now move the adoption of the report and accounts and the payment of the dividends therein set out.

Mr. HENRY HOLMES seconded the motion.

Mr. VARLEY observed that the Company had had a most chequered career. He thought that when the position of the Company had been shown to be what it was so clearly, from the circumstances stated, they ought to get a favourable hearing from the Government in the appeal which the Directors had made to them.

Mr. BIRKS expressed his sympathy with the Directors, who had stuck to the ship so long, and had worked so hard in the shareholders' interests. As to the action brought against them by the Cuba Company, if they really were held by the throat, as the Cuba Company's action suggested, he did not think that it would be such a terrible thing to face liquidation, and afterwards see whether they could not make terms with their natural friends, the Direct West India and the Halifax and Bermuda Cos. He had seen a circular during the last few days from the Direct West India Co., which showed that within two years of their existence they were prepared to pay off £9,000 of their debentures. It appeared to him that they were face to face with a crisis, and he suggested that the Directors should have an interview with the other companies mentioned, and save this company from the claim of the Cuba Company.

Mr. VEARS commended the Directors for their decision to draw on the reserve fund in order to pay the proposed dividends. The shareholders must exercise patience, and he believed that they would ultimately see the cloud now hanging over them disappear.

A SHAREHOLDER called attention to the expenses in connection with the ship the "Duchess of Marlborough," lying at the docks, and advocated the disposal of the vessel in order to save expenses.

Mr. EDWARDS stated that the chairman had compared the revenue of the past half-year with that of the December half of 1897, and had called attention to the decrease in the receipts of £9,500; but he had omitted to mention that the expenditure showed an increase of £1,700. He thought that some explanation was wanted respecting this increase. The position of the Company would be strengthened, he thought, if the debentures were paid off.

The CHAIRMAN: With respect to the small difference that exists between the interest we receive from investments and the amount we pay for debenture interest, we stated at the time that, with regard to this £80,000 of debentures, we should have to pay a premium of 5 per cent. to get rid of them, a fact which, to begin with, diminishes the advantage of paying them off. With reference to the "Duchess of Marlborough," we found from experience that one ship was not sufficient. When the duplication took place—which some gentleman referred to just now as unnecessary, but which we found very necessary—we thought that we could do with one ship instead of two. The little ship now laid up was costing us £8,000 a year when in commission, and that little vessel is kept as a stand-by in case of accident, and is now costing us £400 a year. Although she is kept as a stand-by we keep her with some reluctance, and I may say that we have been endeavouring to sell her, and we are, in fact, now awaiting a reply. With regard to the question of competition with the Direct Company, I am in a difficulty, because what the competition may finally turn out to be, and what we may have to pay to this other company, whichever way the messages go—that question and several other questions depend upon the final decision of the case. We have been very strongly advised, and we are now again told that we ought to succeed on appeal. That is why we are going on with the appeal, and that is why it would be improper for me at the present time to speak of the effects of competition as being this or that when, as a fact, we do not know what it will be until the case is finally decided. The increase in our expenses in 1899 compared with 1897 arose, first of all, from a sum of £500 which had to be spent on the maintenance of land lines. An electrical tramway was started in Jamaica, and the strong current from it interfered with our lines. We therefore had to devise certain measures for protecting our property, and the cost of that, together with the cost connected with the hurricane, amounted to £500. That was an absolutely unavoidable expense. At the stations there was an increase of £372, but this is always a fluctuating item. In further reply to a shareholder, he said: We receive subsidies from the Leeward Islands, the Windward Islands, St. Thomas, St. Croix, Barbados, Trinidad, and Demerara. The Government of Columbia gives us no subsidy.

The motion was carried unanimously; and resolutions were afterwards passed re-electing the retiring Director, Mr. W. B. Kingsford, and the retiring auditors, Messrs. Deloitte, Dever, Griffiths and Co.

A cordial vote of thanks to the Chairman and Directors terminated the proceedings.

India Rubber, Gutta Percha, and Telegraph Works Co. (Ltd.).

The half-yearly general meeting was held yesterday, the Hon. HENRY MARSHAM presiding.

Mr. R. K. GRAY having read the notice calling the meeting,

The CHAIRMAN said: I shall, as usual on these occasions, make a few remarks which will doubtless prove of interest. I am glad to state that the company's turnover in general business continues to show an increase when compared with the similar months of last year, and that although in certain lines there has been a considerable decrease, yet this decrease has been more than balanced by the increase in other directions. In addition to this increase of general business we have had more submarine cable work to do. Our steamer "Silvertown" is now loading at our moorings in the Thames, and will in a few days sail to lay about 1,000 miles of cable between Canso (Nova Scotia) and New York. We hope we shall be fortunate enough to complete this cable with our usual despatch, and so enable the "Silvertown" to return to England just as we are on the point of completing the manufacture of a cable which we have to lay between Waterville (Ireland) and Weston-super-Mare. The "Silvertown" has lately been thoroughly overhauled, and a considerable amount of money has been spent in doing so. The steamer "Dacia" returned safely from her voyage to the West Indies, where she was employed in work which I reported at the ordinary general meeting. The steamer "Buccaneer" is now on charter to the Western Telegraph Co. While making these favourable remarks as to the employment of your works, ships, and staff, I wish to impress on you the fact that competition is keen, the price of raw material is high, and that the coal we consume costs us per ton about 25 per cent. more than we were paying in the spring of 1899. I now move that an interim dividend of 2½ per cent. (or 5s. per share) be paid, free of tax.

Mr. S. WM. SILVER seconded the motion, which was carried unanimously.

A vote of thanks to the chairman terminated the proceedings.

Castner-Kellner Alkali Co. (Ltd.).

The fourth ordinary general meeting of this Company was held yesterday, Mr. WILLIAM MATHER, M.P., presiding.

The CHAIRMAN said the working of the Company's process had been, in every respect, all the board could desire, and it improved from year to year. The concern, from its initiation, had been conducted more like a private partnership than as a public company with a board of directors who only occasionally met. His colleagues and himself had devoted as much time to this enterprise as anyone could be expected to devote to a property of their own. Perhaps to that may be attributed the fact that, in a comparatively short time, they had succeeded in creating an entirely new industry, and obtained such results as were disclosed in the report. During the past four or five years the board had been largely assisted by the late Mr. Hamilton Castner, who was, to a large extent, the inventor of the process. The Matthieson Alkali Co. in America had developed into a very successful concern. That company, with which this company was in close alliance, had been singularly successful in working, as they possessed very cheap power—the Niagara Falls. The development of that company promised to be much greater than could possibly be hoped for in this country, or perhaps in Europe. His remarks applied to that department of the Matthieson Alkali Co. concerned in the working of the Castner process. He then moved the adoption of the report.

Mr. F. HARDCASTLE second the motion.

Replying to questions, the CHAIRMAN explained that the plant of the company was maintained in thoroughly efficient order throughout the year. The staff that had to be kept to ensure that the electrical efficiency of the cells never fell below a fractional point of the requisite high standard, necessitated a constant expenditure on plant, and was not required in any other industry with which he was acquainted. Therefore, at the close of the year the plant was practically in the same condition as at the beginning. Apart from the cost of maintenance of plant, it was proposed to carry £10,000 to depreciation. The increase of about £20,000 in the item of land, buildings, plant, &c., was explained by additions considered advisable in the interests of the business. The report was adopted, and the proposed dividend of 8 per cent. agreed to.

Isle of Man Tramways and Electric Power Co. (Ltd.).

At the annual meeting held on Friday,

Mr. J. R. COWELL said he was elected a director in March last year, and soon afterwards went to America for six months, and on returning was laid up. The first notice he received to attend a meeting of the board was for Feb. 7 last, four days after the failure of Dumbell's Bank. He proceeded to carefully examine the affairs of the company, and found

Digitized by Google

them to be in an exceedingly difficult condition, but he did not resign, as he thought it would have been cowardly to have done so when his colleagues were faced with serious difficulties. Messrs. Turquand, Youngs and Co. had been appointed to audit the accounts independently, and when their exhaustive report was issued the Board endeavoured to get financial assistance, but without avail. Meanwhile, as there was a difficulty in keeping the line running and staving off creditors, the expenditure was cut down to the lowest point. The liabilities of the general undertaking were £84,967, and adding £10,000 for working capital, £95,000 was arrived at as the amount required for the general undertaking. For the separate Ramsey undertaking, he estimated that £35,000 would be required. He described Messrs. Turquand, Youngs and Co.'s report as extremely severe and in some parts hardly fair. He admitted that steps should long ago have been taken to increase the capital, and remarked that if Messrs. Aldred, the auditors, had exercised that care and strictness which they might have done the shareholders would not now be in their present unfortunate position. The Board had every confidence in their late chairman. The auditors had last year, six days before the annual meeting, sent in a supplementary report recommending an immediate increase of capital, but immediately on its receipt, and before it was even read by the secretary, it was taken away by Mr. Bruce, who never communicated its purport to the directors or secretary. He estimated that after increasing the capital of the general undertaking and providing for all existing additional charges, the amount available for dividend would be £2,447, which represented 3 per cent. on preference shares and left a small balance. As to the separate undertaking, he estimated £12,000 would be required to pay all charges, and that shareholders could expect nothing. He considered the prospects of the company were hopeful.

Mr. YOUNG, the late secretary, said he had resigned in 1898 on account of the friction with the directors. He had frequently urged lower dividends and a depreciation, but got no support. The position of the company in February, 1893, was so weak that the Board passed a resolution to include in the revenue accounts as profit £6,000 said to be a portion of the profits made on the purchase of the engines, &c., for Laxey to Ramsey tramway, and the auditors agreed that this was a perfectly legitimate course. He protested, and the matter was so strained that he tendered his resignation as secretary and called in the aid of the legal advisers of the company, with the result that the resolution previously passed was rescinded, and the dividend from that balance-sheet was reduced by 1 per cent. Notwithstanding this, at the Board meeting in September, 1898, a dividend at the rate of 7½ per cent. was declared. On the chairman announcing that a profit of £10,000 had so far been made on the construction and equipment of the Ramsey line, he (Mr. Young) was dumbfounded. The dividend warrants were sent out, and his notice of resignation was sent to the chairman at the same time.

The CHAIRMAN moved the adoption of the report and balance-sheet.

Mr. MITCHELL ECCLES opposed the motion, and declared that in the face of Messrs. Turquand, Youngs and Co.'s report the meeting would not accept the balance-sheet before them.

The CHAIRMAN suggested the appointment of a committee of investigation representative of the shareholders and creditors. This course was agreed to, and the meeting adjourned to June 15th.

Telegraph Manufacturing Co. (Ltd.).

The directors' report for year ended March 31, 1900, states that the profit on the year's working was £41,284. 0s. 2d., which, with the amount from last year (£5,161. 15s. 3d.) amounted to £46,445. 15s. 5d. From this sum the managing director's salary (including a special grant to him of £1,000) and the directors' fees, amounting in all to £2,400, the preference dividend for the year, £4,833. 6s. 8d., and the interim dividend paid in December, £3,000, have to be deducted, and after placing to depreciation account £3,887. and to reserve £17,500, there remains a balance of £14,825. 8s. 9d., which the directors recommend shall be dealt with as follows: In payment of a further dividend at the rate of 14 per cent. per annum for the half-year (7s. per share), and a bonus of 2 per cent. (2s. per share), both tax free, being in all at the rate of 12 per cent. for the year, and that the balance, £5,825. 8s. 9d., be carried forward. During the period the works have been fully employed, and to meet the increasing trade large extensions have been made, and are still in progress, in consequence of which the directors will submit a resolution proposing that the capital of the company be increased by the creation of 20,000 additional ordinary shares of £5 each. The shares are to be offered, in the first instance, to the ordinary shareholders.

REUTER'S TELEGRAM CO. (LTD.)—The annual meeting of this company was held on Wednesday. The chairman (Admiral Sir J. C. D. Hay) said the year 1899 was an eventful one from the standpoint of a newsagency. At present they had 30 special correspondents engaged at the seat of war in South Africa. If they had not on all occasions given such an efficient service as could have been wished, the fault must be attributed partly to the restrictions imposed by the military censors and partly to the strain thrown both on the South African land lines and cables by the enormous number of messages which had had to be telegraphed. On many occasions, particularly at Ladysmith, runners failed to get through with despatches, having either been captured or killed by the enemy. Despite occasional shortcomings, the company's telegrams appeared, on the whole, to have given satisfaction to the Press, particularly by their uniform accuracy. The report was adopted, and a dividend of 5 per cent. declared.

RUSTON, PROCTOR, AND CO. (LTD.)—Col. G. M. Hutton, C.B., presiding over the annual meeting on Wednesday and said the policy inaugurated by the directors of keeping pace with the times in regard to plant and tools had been continued during the past year, the total outlay under that head being £20,521. 5s. 1d. The introduction of complete telephonic communication with the woodworks had been borne out of revenue. The stock in trade at Lincoln and abroad amounted to £248,836, and at the same period of 1899 was £289,000. The actual profit for the year was £48,159, against £45,674 in 1899, an an increase of £2,484. After allowance for depreciation and other items there was £28,659 left, which it was recommended should be disposed of by payment of a dividend of 7 per cent. for the year (absorbing £17,500), transferring to equalisation account £10,000, and carrying forward £1,115.—At an extraordinary meeting the chairman explained that it was necessary to extend the company's works and premises, and the directors had come to the conclusion that the most satisfactory way of dealing with the matter would be to issue 10,000 shares of £10, at a premium of £1 per share to the present shareholders. A resolution to this effect was adopted.

NEW COMPANIES, STATUTORY RETURNS, &c.

BRITISH ELECTRIC PLANT CO. (LTD.)—This company was registered in Edinburgh on May 26, with a capital of £100,000 in £10 shares, to carry on the business of electrical and general engineers, electric plant manufacturers, machinists, founders, &c. The subscribers, with one share each, are: J. G. Stewart, T. Lander, Wilfred Z. Spence, W. Dick, W. Tod, J. Allen, and J. Mackenzie. The first directors are: J. G. Stewart, T. Lander, W. Dick, and Wilfred Spence.

ELECTRIC SUPPLY CO. OF VICTORIA (LTD.)—This company was registered on May 26, with a capital of £200,000 in £1 shares, to carry on in Victoria (Australia) or elsewhere, the business of electricians, electrical and mechanical engineers, suppliers of electricity, makers of electrical appliances, contractors, &c.

WILLIAM M'GEOCH AND CO. (LTD.)—This company has been registered in Edinburgh, with a capital of £100,000, in £1 shares, to acquire and carry on the business of manufacturers of and dealers in electric light fittings, ironmongers, &c., hitherto carried on by Messrs. W. M'Geoch and Co. in Glasgow, Birmingham, and London.

MELDRUM BROS. (LTD.)—This company was registered on May 12, with a capital of £125,000 in £1 shares, to acquire the business of Meldrum Bros., and to carry on the business of mechanical engineers, furnace makers, electrical engineers, manufacturers of mechanical stokers, &c. The first directors are J. J. Meldrum (chairman), T. F. Meldrum, and J. W. Meldrum.

STAINES AND EGHAM LIGHT RAILWAY CO. (LTD.)—This company was registered on May 19, with a capital of £1,000 in £1 shares, to construct, maintain and control light and other railways and tramways, to supply electrical and other power, and to carry on the business of engineers, electricians, &c.

WEAR ELECTRICAL ENGINEERING CO. (LTD.).—This company was registered on May 25, with a capital of £5,000 in £1 shares, to carry on the business of electricians, electrical engineers, manufacturers of electrical apparatus and appliances, mechanical engineers, &c. The subscribers, with one share each, are:—J. G. Kirtley, G. W. Bain, T. Harrison, W. Burns, F. J. Trewhitt, T. S. Roden, and A. White, electrical engineer; the first directors are: , J. G. Kirtley, G. W. Bain, T. Harrison, W. Burns, and F. J. Trewhitt.

CITY NOTES.

MEMORANDA.—Bank rate 3½ per cent. (since May 24, 1900). Price of silver 27 5/16d. per oz. (May 31). Consols (2¾ per cent.) 102⅞—103 for money, 103—103⅛ for account; 2½ per cent. 99½—100 (May 31). Stock Exchange Settling Day: Consols, June 1; Stocks and Shares Continuation Days, June 12 and 26; Ticket Days, June 13 and 27; Pay Day, June 14; Mining Share Carry-over Days, June 11 and 25.

CITY AND SOUTH LONDON RAILWAY CO. (LTD.)—A special meeting of shareholders will be held on the 12th inst. for considering and approving the Baker-street and Waterloo Railway Bill.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH CO. (LTD.)—Letters of allotment in connection with the recent issue to shareholders of the balance 50,000 shares have been posted.

ELECTRICAL JOINT STOCK DEVELOPMENT IN ITALY.—In 1899 114 new companies were registered in Italy, with a capital of £9,040,000, against 66 companies in 1898 and a capital of £3,680,000. In 1896-97 the capital of new companies only amounted to £1,600,000 in the two years. This total for the four years of £14,320,000 is, in the main, represented by the great development of electrical enterprise in Italy. There can be no doubt this country has an important industrial future before her, and that she offers a productive field for foreign capital and energy judiciously employed and directed. The greater portion of foreign capital at present invested in Italian industry, which now represents a very large sum, is German and Swiss.

IMPROVED ELECTRIC GLOW LAMP CO. (LTD.)—A private meeting of this company was held yesterday (Thursday) at Cannon-street Hotel, London.

ROLLER BEARINGS CO. (LTD.)—The committee of shareholders appointed on April 26 to confer with the directors as to the present position and possible future of this company recommends a reconstruction.

Digitized by Google

The company was formed in 1896 with a capital of £150,000 in 6 per cent. cumulative preference and ordinary shares. The prospectus profits were estimated at the rate of 10 per cent. per annum on the ordinary shares after the payment of preference dividends. The public subscribed for rather less than one-fourth of the issue. The purchase price of the patents acquired by the company was £91,000, £15,500 in cash, £37,500 in preference, and £38,000 in ordinary shares. The small amount of working capital subscribed by the public speedily decreased, and the company's operations, unless further working capital is now provided, must apparently cease. A loss was incurred on the first year's trading of £1,865, on the second year £2,310, and the total trading loss to September last was £8,560. Other losses increase this total to over £10,000, and neither preference nor ordinary dividend has ever been paid. The chief reasons assigned for this condition of affairs is (*a*) that the cost of management has been altogether disproportionate to the amount of business done by the company, and (*b*) that heavy expenses have been incurred in connection with "unsuccessful experimental bearings." This is, briefly, the state of affairs which the shareholders were called upon to discuss at the meeting held on Wednesday at the Westminster Palace Hotel. A circular which has been issued to the shareholders justifying the appeal for further working capital states that "better material and better workmanship are needed in manufacturing the roller bearings," for which it is believed that "for certain purposes, notably electric traction, there is a good prospect of profitable business in the future." The shareholders are invited in order to obviate the company going into liquidation, to make all shares of the same class by (1) abandoning all preference and all arrears of dividend; (2) making an absolute transfer of one quarter of the shares in favour of a trustee, such trust shares to be utilised for the purpose of placing £5,000 of debentures; (3) creating £5,000 first mortgage debentures of £5 or £10 each, bearing interest at 5 per cent. per annum, each subscriber for the debentures to receive out of the shares surrendered as mentioned five bonus shares for each £1 subscribed in cash. £5,000 is the minimum which, it is urged, would justify the directors in proceeding with the scheme. Truly a novel and drastic proposal.

STOCK EXCHANGE NOTICES.—The Stock Exchange Committee has been asked to appoint a special settling day in 180,000 vendors' £1 fully-paid ordinary shares (Nos. 1 to 180,000) and 25,000 vendors' 7 per cent. non-cumulative £1 fully-paid preference shares (Nos. 115,001 to 140,000) of *Nernst Electric Light (Ltd.)*.

TELEGRAPH MANUFACTURING CO. (LTD.)—Notice is given that the ordinary general meeting of this company will be held at the Law Institution Rooms, Cook-street, Liverpool, to-day (Friday), June 1, at 3 p.m. After the ordinary meeting a resolution will be proposed for increasing the capital of the company to £300,000 by the creation of 20,000 additional shares of £5 each. The transfer books are closed from May 25th to June 9th inclusive.

NOTES.

WE publish in another column an interesting Paper by Mr. C. W. SCHAEFER on "Simultaneous Testing as applied to Fault Localisation in Submarine Cables," in which he gives some practical examples of the method suggested by him in a previous article contributed to *The Electrician*, Vol. XL., p. 17. Although there is no claim to originality in his communication as regards the theory of fault-testing, the method he employs is strikingly simple and accurate, and undoubtedly reduces the liability to personal error or that due to a want of manipulative skill in the observer. The facts themselves, however, are all well known to those employed in this kind of work, and Mr. SCHAEFER'S method would seem to be simply a novel way of applying them. Thus, an ordinary bridge reading to "false zero" gives $x + \frac{fy}{f+y}$, where x and y are the resistances on either side of the fault and f the resistance of the fault itself. By observing the ratios of the two currents the ratio of f to y is obtained, which is all that is necessary.

Mr. SCHAEFER is quite right in insisting upon the importance of simultaneous observations; and it is principally, we understand, for this reason that the majority of cable-repairing steamers are now provided with dead-beat galvanometers, which by enabling observers to obtain readings in rapid sequence, are almost equivalent in value for localisation purposes to simultaneous observations. With such variable faults, however, as those described in Mr. SCHAEFER'S Paper—one of which is peculiarly interesting—absolute simultaneity is imperative if results are to be comparable, and it is doubtful if any other method than the one described would have been equally successful in the circumstances. For a long time difficult high resistance faults were usually localised by the "fall of potential" test, or the bridge modification of it. This is, of course, a simultaneous method, potentials being observed instead of currents, but it has now been almost universally superseded by the "earth overlap" test, partly on account of the latter's simplicity. The results obtained by the potential test were always very variable owing to the difficulty in estimating and correcting for the E.M.F. set up at the fault, and it is probable that the error due to this cause is less when measuring currents than when observing potentials—a view which is borne out by the fact that in general practice observations obtained with the distant end of the cable earthed are invariably steadier and more reliable than those measured with the cable end free. It is for this reason also that the "earth overlap" method is so undoubtedly superior to the "overlap free," although theoretically they should be equally accurate.

THERE can be no doubt that the subject of fault localisation is one of extreme importance, especially to submarine cable companies, in whose repair work a mistake in the calculation of the distance of a fault may mean the unnecessary expenditure of costly cable, and therefore any suggested improvement upon existing methods of testing should be especially welcomed and recognised by them. The value of articles, describing, as does Mr. SCHAEFER'S, not only the methods, but the actual tests cannot be over-estimated.

DR. PETERS comments in No. 9 of the *Centralblatt für Accumulatoren und Elementenkunde* on Mr. WADE'S Paper on "Storage Battery Problems." He states that in a series of experiments on positive active material—the results of which have already appeared in *The Electrician*, May 18, p. 186—he found that, when it was in a healthy, good condition, it possessed a density of 7·55 to 7·65, which fell to between 7·02 and 6·48 when the paste on the plates had become softened through being long in use. Dr. PETERS further notes that as it is a hydrated peroxide of lead which is formed in the cell, and one whose density has not yet been determined, it is not safe to make any deductions based on the density of the material as compared with that of pure peroxide of lead, in which the hydration of the electrolytic peroxide is not

Digitized by Google

taken into account. It will be remembered that as long ago as 1887 Mr. DESMOND G. FITZGERALD advocated in *The Electrician* the theory that electrolytic peroxide of lead is either itself hydrated or is admixed with an hydroxide, but the difficulties in the way of experimental proof are very great, and until the recent publication of Dr. PETERS' analyses there have been practically no data bearing on the question to which much weight could be attached.

REVERTING again to Mr. WADE'S Paper, Dr. PETERS, in the following number of the *Centralblatt*, says that too little importance has been attached to the part which persulphuric acid plays in the formation of the active material. In order to investigate this he proposes to place a layer of lead oxide on the bottom of the cell, in which persulphuric acid will be formed by electrolysis, care being taken to raise the anode sufficiently high to prevent contact between it and the lead oxide, and to allow of the free escape of gas; or, in lieu of this, he suggests enclosing the lead oxide between two diaphragms. With reference to the function of persulphuric acid in the cell, we would remind Dr. PETERS that Dr. ARMSTRONG stated in the discussion on Mr. WADE'S Paper that he was at present pursuing research on persulphuric acid, to the presence of which in the cell he and Mr. ROBERTSON were the first to draw attention in a joint communication to the Royal Society in June, 1891 (see *The Electrician*, Vol. XXVII., p. 196).

A recent number of *Science*, of New York, discusses the researches of Prof. CHILD on the phenomena of the electric arc. Prof. CHILD has applied the theory of ionic dissociation to this phenomena, and he explains on this hypothesis the well-known curve, obtained by Mrs. AYRTON, representing the fall of potential between the carbons. According to this hypothesis the curvature at each point in Mrs. AYRTON'S curve represents the density of the charge at each point, and this explanation of the curve is said to be sufficient to settle the extremely perplexing question of the existence of a counter E.M.F. within the carbon arc. Thus it is explained that the work done by the current against the alleged counter E.M.F. is the result of the transference or movement of freshly dissociated ions along the path of the arc, the positive ions having to be pushed up by the impressed E.M.F. into the region of highly positive ions, and the negative ions having to be pulled down, as it were, into the region of highly negatively-charged ions. This explanation is beyond question ingenious, but it can only be held to settle the hypothesis of a counter E.M.F. by substituting a different phraseology for what is practically an identical phenomenon. Prof. CHILD'S conception of the work done in moving ions along a path through a definitely mapped out region of potentials is, in fact, nothing more than another way of conceiving a counter E.M.F. Such an E.M.F. be it observed, is under no necessity to be found at any one particular point in that path, since it is equally a counter E.M.F. when it represents the line integral of the work done in moving a charge along any path where it encounters opposing electric force.

AT the annual general meeting of the American Institute of Electrical Engineers held in Philadelphia last month, Dr. M. I. PUPIN read a Paper on "Telephony over Cables and Long-Distance Air Lines," which, from the reports published so far in our American contemporaries, appears to be of considerable importance. Dr. PUPIN is a follower of OLIVER HEAVISIDE, and has been directing his attention to the question of a practical approximation to a distortionless circuit for the purpose of telephoning through cables or over long distances. He starts with HEAVISIDE'S result that it is advantageous to distribute inductance along the length of the cable, and, referring to the difficulty of obtaining sufficiently high inductances uniformly distributed throughout the line, he proceeds to discuss mathematically what is the least subdivision necessary to obtain good results. This part of the Paper is, however, not reproduced in the abstracts before us, and we reserve our comment on it until we have received the complete text.

IT was the second part of the Paper, in which actual experiments are recorded, that aroused most interest at the meeting. An artificial line was made up, consisting of 250 sections having resistance and capacity, and between these sections inductance coils could be connected. Without the inductance coils, transmission was "good" through 50 sections, "fair" through 75 sections, and "impracticable" through 100 sections. With the inductance coils connected between the sections, conversation could easily be carried on through all the 250 sections, the articulation being clear.

THESE results are worthy of careful consideration, but it will be necessary to have further numerical details as to the relative values of the four line constants, resistance, capacity, insulation, and inductance, and also to know the actual local circumstance of the experiments, before definite conclusions can be drawn as to their practical applicability. For instance, the distance in feet as well as the distance in ohms between the inductance coils will have a bearing on the test, for in the extreme case of the coils being too near to one another all the energy might be simply transmitted by induction from the first coil to the last, the capacity of the cable being perhaps sufficient to prevent the interference of the current waves transmitted by conduction. We have a dim recollection of a successful experiment, carried out several years ago, of telephoning through a long cable coiled up in a tank at a cable factory. On this occasion, however, congratulations were interrupted by the discovery that the two ends of the cable to which the telephones were connected did not belong to the same piece. We do not wish to suggest that Dr. PUPIN has not taken every precaution to preserve the required experimental conditions in his test, including the avoidance of inductive short-circuits of this nature; but, nevertheless, it is safer to await the receipt of his actual Paper before regarding the results mentioned above as absolutely conclusive.

French Academy of Sciences.—M. Darboux has been elected permanent secretary for the mathematical science sections of the French Academy of Sciences, in place of the late M. Bertrand.

Canadian Electrical Association.—Owing to the recent disastrous fire at Ottawa the meeting of the next Convention cannot be held in that city as intended. A new meeting-place has not yet been decided upon.

Digitized by Google

University College of North Wales, Bangor.—Prof. E. Taylor Jones will begin in October next a systematic course of instruction in electrical measurement and practical electricity. The physical laboratory at the college is fully equipped with plant and apparatus for the study of all branches of practical engineering. Further particulars are given in an advertisement.

Wireless Telegraphy in the French Navy.—The French Government have decided to equip the whole of their Mediterranean squadron with wireless telegraphy installations. Demonstrations made between the Government vessel "Utile" and the coast forts showed that communications could be successfully maintained between ship and shore at distances of 60 miles between them.

City and Guilds of London Institute.—The session 1900 1901 of this Institute's Central Technical College, Exhibition-road, and the Technical College, Finsbury, commences in October. The entrance examinations to both colleges are held in September. Some further particulars are given in an advertisement, and all information can be obtained from the colleges or from the head office, Gresham College, Basinghall-street, E.C.

Cable Interruptions:—

	Date of Interruption.
Latakia—Cyprus	June 21, 1899
Cayenne—Pinhieros	Oct. 11, 1899
Tangier—Tarifa	Jan. 3, 1900
Paramaribo—Cayenne	Feb. 16, 1900
Ceara—Maranham	Feb. 20, 1900
Pará—Maranham	Mar. 2, 1900
Môle-St. Nicolas—Cap Haitien	Mar. 7, 1900
San Thomé—Loanda	May 20, 1900
Durban—Delagoa Bay	May 31, 1900

Extraction of Indiarubber.—A somewhat novel process for the extraction of indiarubber from the tree was recently described in a Paper before the French Society of Civil Engineers. The bark and roots are cut up and soaked in dilute sulphuric acid, and the effect of this is to decompose the woody portions without affecting the indiarubber. A division is thus made between the valuable rubber and the rest of the bark and roots, and it is claimed that the rubber so produced is quite pure. The author stated that 1lb. of indiarubber could thus be produced at a cost of about 2½d.

Personal.—At a meeting of the Court of Governors of the Victoria University, held on the 31st ult., the following names were submitted by the Committee of Honorary Degrees to receive the honorary degree of Doctor of Science: Lord Rayleigh, Sir W. Abney, Prof. A. Michelson (University of Chicago), Prof. H. A. Rowland (Johns Hopkins University), Prof. E. Pickering (Harvard), Prof. J. J. Thomson, Dr. T. E. Thorpe, Mr. Henry Wilde, Prof. Dewar, Sir William Huggins, Sir W. C. Roberts-Austen, Mr. R. T. Glazebrook, and Mr. A. R. Forsyth.——Mr. R. L. Wilberforce, of Trinity College, has been elected to the Cambridge University Lectureship in Experimental Science, formerly held by Mr. W. N. Shaw, F.R.S.

Verband Deutscher Elektrotechniker.—Among the Papers already announced to be read at the annual general meeting of this association, which will be held at Kiel from the 17th to 20th June, are the following: "On the Influence of the Curve-Form of Alternate Current on Iron Losses," by Dr. G. Benischke; two Papers on fire alarms, by Freiherr C. von Moltke and Herr E. Anshagen; "Rail Welding by the Process of Producing High Temperatures by Means of Burning Aluminium," by Dr. Hans Goldschmidt; "Directibility of Apparatus for Wave Telegraphy," by Dr. R. Blochmann, and "The New Bremer System of Electric Light," by Dr. Wedding.

Proposed Memorial to the late Mr. G. J. Symons, F.R.S.—At a meeting of the Royal Meteorological Society held on May 31, it was unanimously resolved that a memorial to the late Mr. G. J. Symons, F.R.S., the distinguished meteorologist and founder of the British Rainfall Organisation, be formed. This memorial was to take the form of a gold medal, to be awarded from time to time by the Council of the Royal Meteorological Society for distinguished work in connection with meteorological science. An executive committee, containing representatives from many of the societies with which Mr. Symons was associated, was constituted to raise funds for this purpose. Contributions will be received by the assistant-secretary, Mr. W. Marriott, 70, Victoria-street, Westminster, S.W.

A Selector System of Wireless Telegraphy.—Messrs. B. S. Cohen and P. H. Cole have recently devised an ingenious selector system for working a number of wireless telegraph stations. After various experiments in this direction the inventors patented a method of synchronising the stations by means of falling mercury drops. The system is described in patent No. 5543[99]. The main or master station sends out successive waves at equal intervals of time, these waves actuating an electromagnet device whereby a mercury drop is liberated simultaneously at all the stations. In its descent each drop passes a number of contacts, closing the message circuits. Thus when a signal wave is sent out at any one station, it is received only by that station in which the receiving circuit is simultaneously closed by the falling mercury drop. To effect this, of course, the stations are connected in rotation to the contacts in the path of the mercury drops. We trust that the inventors will carry their investigations further and develop the system on a larger and more practical scale; for whatever the difficulties may be, there can be little doubt a good selector system would be welcomed by wireless telegraphists.

Patent Office Reforms.—We referred last week in our leading article to the appointment of a committee under the chairmanship of Sir E. Fry to deal with the subject of amending patent procedure. We also gave the text of the reference to this committee. Another departmental committee, presided over by Mr. F. J. S. Hopwood, of the Board of Trade, has completed its investigation into the subject, and has already made a report. As a result of the recommendations of this committee, certain modifications in Patent Office procedure have already been introduced. Among these are the following:—First: It is to be arranged that deposit accounts can be opened with the Patent Office for the supply of Patent Office publications. This will obviate the sending of small sums with each separate order and will also do away with the use of the 8d. postcard which was introduced some time ago, but has not been found altogether satisfactory. Second: It has been decided to reprint some of the specifications which are out of print. It is, however, impracticable to reprint the entire 8,900 specifications which are at present unavailable owing to being out of print. The committee recommend that any specification out of print should be reprinted on the applicant guaranteeing to take not less than six copies at 8d. each. It is further recommended that illustrated abridgments of all the specifications between the years 1617 and 1883 should be published. Another matter raised in the report of this committee, which is about to be published, is the question of notifying patentees of the impending expiration of patents. This recommendation, however, appears to be opposed by the majority of patent agents on the ground that the work of reminding patentees is far better carried out by the patent agent himself. We believe that no decision has yet been arrived at by the Patent Office with regard to this last proposed reform.

MEETINGS OF SCIENTIFIC AND ENGINEERING SOCIETIES, &c.

(To-day) FRIDAY, June 8th.

PHYSICAL SOCIETY.

5 p.m. Meeting in the Rooms of the Chemical Society, Burlington House. Papers to be read: (1) "On the Magnetic Properties of Iron and Aluminium Alloys, Part II.," by Dr. S. W. Richardson; (2) "Note on Crystallisation Produced in Solid Metal by Pressure," by W. Campbell; (3) "On the Viscosity of Mixtures of Liquids and of Solutions," by Dr. C. H. Lees.

ROYAL INSTITUTION.

9 p.m. Evening Discourse on "The Effect of Physical Agents on Bacterial Life," by Allan Macfadyen.

MONDAY, June 11th.

ROYAL INSTITUTION.

5 p.m. General Monthly Meeting.

SOCIETY OF ENGINEERS.

7.30 p.m. Ordinary Meeting at the Royal United Service Institution, when a Paper on "Notes on Electric Traction," by A. H. Binyon, will be read.

CONTEMPORARY ELECTRICAL SCIENCE.

[Compiled by E. E. Fournier d'Albe.]

Penetration of Radium Rays.—H. Becquerel has shown that the transmission of radium radiation across a screen is attended by several distinct phenomena: selective absorption, diffusion, emission of secondary rays, some of which are deflected by a magnet, while others are not; and, finally, a direct transmission of part of the radiation from the source. The transmitted portion appears to be identical with the incident radiation, and suffers the same deflection by a magnetic field. This identity has been doubted by Villard on the ground of some experiments, which seemed to show that the transmitted beam consists of rays which are not deflected by a magnet, while the deflected rays behave like cathode rays, and emerge at right angles to the absorbing surface. Becquerel has therefore repeated his experiments in a modified form. He employed a linear source of radium rays, consisting of a lead block with a furrow containing a radium preparation. A copper wire was placed a few millimetres above the furrow and parallel to it. Above that again was placed a sensitive plate wrapped in black paper, and the shadow cast by the copper was photographed with and without a magnetic field. Under the influence of the latter, with its lines of force parallel to the copper wire, the rays describe circular arcs of slight curvature, and by reversing the field two shadows may be obtained which are displaced with respect to each other. When a sheet of aluminium is introduced, either above or below the copper, these two images are obtained in the same manner, showing that the rays transmitted by the sheet are also deflected by a magnet. Villard's contrary result is probably due to a peculiar effect of the edge of the screen, which has been fully accounted for by the author.

[H. Becquerel, *Comptes Rendus*, April 30, 1900.]

Transient Deflection of Cathode Rays.—In 1896 Jaumann described a peculiar experiment which has not yet been satisfactorily accounted for. He immersed a very highly exhausted vacuum in ordinary vegetable oil. The tube was provided with a single electrode, which served as a cathode, while the anode was outside the tube and in the oil. When the tube was working the approach of a charged glass rod apparently produced a repulsion of the beam of cathode rays and the fluorescent spot produced by it. This repulsion rapidly subsided while the glass rod was held in the same position. When the rod is removed, or when the charge is of the opposite sign, the repulsion becomes an attraction. P. Villard has repeated the experiment and verified the effects as stated, but he does not follow Jaumann in ascribing them to a peculiar property of the cathode rays, such as the "self-stretching" property which the latter connected with his hypothesis of "longitudinal light." The author points out that commercial oils are very poor insulators, whereas true dielectrics have been shown by Bouty to intercept an electrostatic field as effectively as a layer of mercury. Consequently the electrostatic field produced in the interior of the tube by the glass rod outside depends upon the conductivity of the oil, and if the oil takes some time to adjust itself to an external field, there will be an electrostatic process within the oil which may well last a second. Such a process would explain the temporary deflection of the cathode beam described. In confirmation of this explanation the author replaces the cathode beam by a conductor joined through a screened wire with an electroscope outside. A temporary deflection of the electroscope is then observed, corresponding to the deflection of the cathode beam.

[P. Villard, *Comptes Rendus*, April 30, 1900.]

Luminous Effects on Wires.—A metallic wire which is not covered by an insulating layer becomes covered with a luminous aureole when it is inserted in the circuit of an induction coil containing a spark-gap or a vacuum tube. J. Borgman has further invested this phenomenon by means of wires sealed into cylindrical tubes, and traversing their axis. The tubes were several feet long and 3cm. to 6cm. wide. Some of the tubes were traversed by capillary glass tubes containing liquid conductors. As exhaustion proceeds, the luminous phenomena show a peculiar development. The aureole decreases in intensity, and is gradually replaced by a series of equidistant stars, around which luminous discs are formed with their planes at right angles to the wire. The number of stars and discs increases, until the latter touch each other and fill the whole tube with a luminosity having a slightly stratified aspect. These effects are the same whether the tube is attached to the positive or the negative terminal of the secondary. When a spark-gap is inserted in parallel with it, and the wire is attached to the negative terminal, there is only a continuous luminous envelope, which broadens out as exhaustion proceeds and finally detaches itself from the wire. The stars reappear on attaching the wire to the positive terminal, and at a certain pressure the discs reappear also, their diameter increasing with the length of the spark-gap. As exhaustion proceeds, the number of discs decreases, some of them remaining, while others disappear. Finally, they are transformed into nebulæ with a starry nucleus. The approach of a magnet has the effect of inclining the plane of the rings.

[J. Borgman, *Comptes Rendus*, April 30, 1900.]

Velocity of Ions.—The velocity of ions in a gas ionised by Rontgen rays has been determined by Zeleny, Rutherford and others, by first determining the sum of the velocities of the positive and negative ions, and then the ratio of the same velocities. J. Zeleny has now made a direct determination of the velocities in question by balancing them against the velocity of a stream of gas. The gas was made to flow between two concentric cylinders, which were maintained at different potentials. By passing a narrow beam of Rontgen rays through the cylinders at right angles to their length, a narrow layer of ionised gas was produced. Owing to the electric field between the two cylinders, the ions of this layer tended to move radially towards, or away from, the axis of the two cylinders, but at the same time they were carried along by the stream of gas. For obtaining the difference of potential which must be used to allow the ions to be carried a certain distance along the tubes by the gas stream, the inner cylinder was divided at some distance from the beam of rays into two parts insulated from each other. That one of these which was not traversed by the rays was connected to a pair of quadrants of an electrometer, so that it was possible to tell when any ions reached it. The gases studied were air, oxygen, carbonic acid, and hydrogen, both moist and dry. The presence of moisture diminished the velocity, except that of the positive ions in moist air and moist carbonic acid. The ionic velocities obtained range from 0·76 (CO_2) to 8cm. per second (H) in a field of one volt per cm. The negative ion is the faster, except in moist CO_2. But the charge of both is equal, and probably equal to the electrolytic charge of hydrogen.

[J. Zeleny, *Proc. R. Soc.*, April 14, 1900.]

Dual Nature of Radium Rays.—P. Villard describes an instructive experiment which brings out clearly the heterogeneous nature of the rays given out by "radium" preparations. Radium rays are transmitted through a slit in a lead plate, and impinge at nearly grazing incidence upon two sensitive plates laid one over the other and wrapped in black paper. The rays are exposed to a strong magnetic field. It is evident that under these circumstances the upper plate receives rays which have traversed the black paper only, while the lower one receives rays which have traversed in addition the glass and film of the upper plate, and an increasing thickness of both as the angle of incidence increases towards the edge. On development the upper plate shows two impressions—one deviated and spread out, the other feebler, but absolutely rectilinear and sharp. On the lower plate only one impression is visible, that due to the non-deflected rays. The impression is as clear as that on the upper plate, and indeed clearer, if anything, owing to the absence of fog. A prolonged exposure brings out a very feeble indication of the deflected rays. A band of lead 0·3mm. thick, laid across the upper plate, intercepts the deflected rays over its whole width, whereas the rectilinear rays are only weakened. Thus the two classes of rays may be distinguished from each

Digitized by Google

other in the region where they are superposed. The author simply calls the two classes of rays X-rays and cathode rays. Taking these names in a wider sense, there seems to be no objection to their use in this manner, especially as there remains no quality which could serve to distinguish the two kinds of radium rays from the two classes of rays obtained from vacuum tubes. But if their identity is finally established, it will be obviously necessary to substitute another name for cathode rays, a cathode not being essential to their generation.

[P. VILLARD, *Comptes Rendus*, April 30 1900.]

Atomic and Molecular Magnetism.—Some further interesting work has been done by S. Meyer on the atomic magnetism of the elements and the manner in which it is affected by the combination of atoms to form molecules. Measurements made with vanadium chloride show that is a somewhat feebly paramagnetic substance of susceptibility about one-quarter of that of nickel. Provisionally, it may be placed at the beginning of the series of susceptibilities of the iron elements discovered by the author, thus

$$V:Ni:Cr:Fe^1:Co:Fe:Mn = \tfrac{1}{2}:2:2\tfrac{1}{2}:3:4:5:6.$$

Studies of gadolinium and samarium make it appear likely that both these metals contain traces of a new substance of very high susceptibility. This new element is revealed in the spectrum, which shows a large number of lines, and this, as we know from the author's researches, invariably indicates a high susceptibility. Special attention was devoted to the salts of copper. Previous work had shown that in some diamagnetic compounds the molecular magnetism shows a greater diamagnetic value than would correspond to the sum of the atomic magnetisms. This happens in every case where the combination is accompanied by a considerable expansion, as in the iodides of silver, mercury and lead. This suggests that the converse might occur in the case of contraction of volume, and for this investigation the salts of copper, with their very small susceptibilities, are specially valuable. Measurements made on a number of copper salts show that there is no fundamental difference between cupric and cuprous salts in Wiedemann's sense, since both the sulphides are equally diamagnetic. But the influence of volume changes is very decided and regular. Volume expansion increases the diamagnetic character of a substance, and contraction emphasises its paramagnetic character. The magnetic properties of the elements can therefore only be deduced from the elements themselves, or from compounds which undergo no change of volume during their formation.

[S. MEYER, *Ann. der Phys.*, No. 4, 1900.]

ELECTROMAGNETIC THEORY.—CXV.*

BY OLIVER HEAVISIDE.

(*Continued from p. 921, Vol. XLIV.*)

§ 463. In Vol. I., § 164, it was shown that a point charge q in steady rectilinear motion along the axis of z, at a speed u, less than v, was associated with the potential

$$V = \frac{q}{4\pi c\{z^2 + \kappa^2(x^2+y^2)\}^{\frac{1}{2}}}, \quad (1)$$

where $\kappa^2 = 1 - u^2/v^2$, a fraction ranging from 1 to 0, as u increases from 0 to v. Here it is to be understood that V is the potential at the point x, y, z when the origin is at the charge, so that V accompanies q in its motion. It is further to be understood that the electric force is derived from the potential in the eolotropic manner specified by

$$\mathbf{E} = -(i\nabla_1 + j\nabla_2 + \kappa^2 k\nabla_3)V. \quad (2)$$

The displacement is obtained by multiplying by c, as usual. The result, as regards the displacement, is therefore the same as if the charge were at rest, but the permittivity in the direction of z both ways were reduced from c to $\kappa^2 c$. This produces a lateral concentration of the displacement, with the ultimate result that when u is increased to v, the displacement is entirely in the equatorial plane, forming an impulsive plane wave with circular magnetic force. In any case, the magnetic force is the vector product of the velocity **u** and the displacement **D**.

The question now to be considered is what occurs when u is greater than v. Are the formulæ still valid? We can see immediately that some reservations are necessary, even though no change of formula may be required. For κ^2 is now negative; and V, and also **E** and **H** are made imaginary when

$$z^2 < \kappa^2(x^2+y^2), \text{ or } z^2 > s^2(x^2+y^2), \quad (3)$$

where

$$s^2 = u^2/v^2 - 1 = \operatorname{cosec}^2\theta - 1 = \cot^2\theta. \quad (4)$$

This means that V is real inside the two cones to right and left of the moving charge whose angles are 2θ, connected with s^2 by equation (4), but unreal in the intermediate region outside the cones. We must certainly reject the unreal V, because this is a matter of physics ultimately, not of possible mathematics. In Vol. II. were numerous formulæ relating to waves which had no existence when they assumed unreal meanings. Certainly it is the same thing here.

But next, seeing that disturbances are propagated only at speed v, whilst the charge q moves at the greater speed u, the locus of the spherical waves sent out by the charge as it moves along forms the *left* conical surface only. So we must reject the right cone altogether, if we are considering a charge brought from rest up to speed u.

So far is rejection without change. But closer consideration will make it probable, if not certain, that a change in the formula is wanted as well. For, assuming that equation (1) is correct when κ^2 is negative, provided we keep to real values,

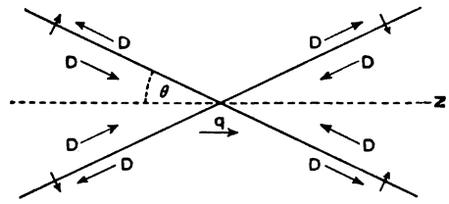

FIG. 23.

it still belongs to both cones. Now it was standardised so as to make the total displacement leaving the charge be q. This was with $u < v$, when the displacement emanated in all directions. As we employ now the same formula, the same property should hold good, keeping to the real values, however. But V is symmetrical. At corresponding points in the two cones V is the same. So the displacement leaving q for the right cone can be only $\frac{1}{2}q$, and similarly for the left cone. The practical meaning is that if we reject the right cone, and still have the charge at the apex of the left cone represented by q, we must double the right side of equation (1). That is to say,

$$V = \frac{q}{2\pi c\{z^2 - s^2(x^2+y^2)\}^{\frac{1}{2}}}. \quad (5)$$

should be the proper solution. Similarly, the right members of the formulæ for **E** and **H**, true when $u < v$, must be doubled when $u > v$. I gave this result in 1892, El. Pa., v. 2, p. 516, footnote, having obtained it by a straightforward operational process, to be given later. It is possible, however, that some readers may find the above reasoning sufficiently convincing. It is plausible enough, but by no means demonstrative, on account of the infinite values concerned, which evade evaluation. There are two ways of corroborating equation (5), viz., to use it to construct a known solution, and to prove it directly from the operational solution. The first way is much the easier.

At any point P inside the cone, we have

$$V = \frac{q}{2\pi c}\frac{\tan\theta}{\{z^2\tan^2\theta - (x^2+y^2)\}^{\frac{1}{2}}}, \quad (6)$$

or

$$V = \frac{q}{2\pi c}\frac{\tan\theta}{(PQ \times PR)^{\frac{1}{2}}}. \quad (7)$$

The last form shows the meaning, the second denominator expressing the geometrical mean of the two parts into which

* All rights are reserved.

Digitized by Google

P divides the diameter QR. So V is a minimum on the axis, and increases to infinity on the cone. Outside the cone V is zero. Deriving the electric force by equation (2), it will be found that **E** is radial, and is directed *towards* the charge. This is inside the cone. Its size is

$$\mathrm{E} = \frac{q}{2\pi c}\,\frac{r\tan\theta}{l^3}, \qquad (8)$$

at distance r from the apex, where l is the above-mentioned geometrical mean. The conical surface is the seat of a sheet of displacement away from the apex. This follows because V suddenly drops to zero outside the cone. The amount of displacement in the sheet at QR going outward must exceed the amount crossing QPR radially towards the apex by the amount q. This is obvious by the meaning of electrification in relation to displacement.

A difficulty arises here. For on integrating the flux of D inwards across QPR, according to (8), the result is infinity, the infinite part arising at the boundary. So the outward flux on the outside must be also infinity, plus q. The meaning of this double infinity will appear later.

Now use equation (6) to calculate V by integration in the case of an electrified line moving transversely. We know the result already, so can disprove equation (6) if it does not work properly. Let σ be the linear density of the electrified line. Then, by (6),

$$\mathrm{V} = \frac{\sigma}{2\pi c}\int \frac{\tan\theta\, dx}{(z^2\tan^2\theta - x^2 - y^2)^{\frac{1}{2}}}, \qquad (9)$$

where x is the distance of dx from the plane of the paper in

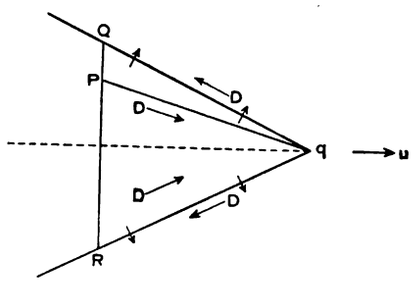

FIG. 24.

Fig. 24, it being supposed that the electrified line passes through q, and y is measured upward on the paper. To find the limits, observe that every element of the electrified line has its cone to correspond, of angle 2θ, and that those portions only of the line contribute to V whose cones cover the point in question where V is wanted. The extreme cones therefore have the point on their surfaces. Therefore

$$z^2\tan^2\theta - x^2 - y^2 = 0,$$

or

$$x = \pm(z^2\tan^2\theta - y^2)^{\frac{1}{2}} \qquad (10)$$

at the limits. The net result is that (9) includes all real values. The integral is an easy one, and makes

$$\mathrm{V} = \frac{\sigma}{2\pi c}\tan\theta\left[\sin^{-1}\frac{x}{x_0}\right]_{-x_0}^{+x_0}, \qquad (11)$$

where x_0 is given by (10). Or, finally,

$$\mathrm{V} = \frac{\sigma}{2c}\tan\theta. \qquad (12)$$

So V = 0 everywhere outside the two planes which envelop the cones, and V has the constant value just written inside the planes. This means that there is no **E** or **H** anywhere save at the planes themselves. The total displacement they carry can be estimated by the sudden drop in V in passing through the planes to be $\frac{1}{2}\sigma$ on both; and the magnetic force to correspond satisfies $\mathrm{E} = \mu v \mathrm{H}$, as in all pure plane waves.

Now these results agree with the arrangement in Fig. 10, which was proved. So the proper standardisation of the potential formula for a point charge is assured. In the case of a moving strip of surface density σ and breadth a, the potential is

$$\mathrm{V}_0 = \frac{\sigma a}{2c}\tan\theta, \qquad (13)$$

constant, on the left side of the slab waves; V = 0 on the right side; whilst in the waves themselves V rises uniformly from 0 outside to V_0 inside—that is,

$$\mathrm{V} = \mathrm{V}_0 \times \frac{\mathrm{PQ}}{\mathrm{PR}} = \frac{\sigma}{2c}(z\tan\theta - y) = \frac{\sigma}{2c}\times \mathrm{PS}, \qquad (14)$$

where PS is the vertical distance of P, where V is reckoned, from the outer plane.

Thus the equipotential surfaces are parallel to the wave fronts, and **E** lies in them. This property remains true until u is reduced to v. After that they split, separate, and widen out both ways into closed surfaces, and the disturbance spreads over all space.

In the case of a point charge, the equipotential surfaces are hyperboloids of revolution. The conical surface is the extreme limit, to which the last hyperboloid goes infinitely near. These surfaces become infinitely compressed into one plane when $u = v$. After that, with $u < v$, they split and become flattened ellipsoids, and ultimately spheres, when u is reduced to nothing. The ellipsoidal theory was given in Vol. I., §§ 164 to 167. I should add that Mr. Searle has added interesting developments to the ellipsoidal part of the subject (*Phil. Trans.*, 1896, and *Phil. Mag.*, 1896).

What is not clear in the above is the state of things at and just within the conical surface itself. To elucidate this, consider a more general case—viz., that of the motion of an electrified line of finite length, or at least infinite only one

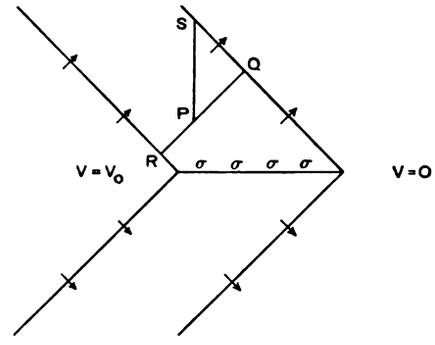

FIG. 25.

way, in its own line. The investigation of V will follow later. The formula is

$$\mathrm{V} = \frac{\sigma}{2\pi c}\log\left\{\frac{z\tan\theta}{h} + \left(\frac{z^2\tan^2\theta}{h^2} - 1\right)^{\frac{1}{2}}\right\} \qquad (15)$$

where

$$h^2 = x^2 + y^2. \qquad (16)$$

This is when the electrified line, linear density σ, is infinitely long one way, its termination being at the origin. The angle θ has the same meaning as before, in relation to the conical boundary of the region occupied by **E** and **H**. Now when the line is of finite length a, the V is the difference of two formulæ of the type (15) having their origins at the two ends of the line. That is,

$$\mathrm{V} = \frac{\sigma}{2\pi c}\log\frac{z\tan\theta + (z^2\tan^2\theta - h^2)^{\frac{1}{2}}}{z_0\tan\theta + (z_0^2\tan^2\theta - h^2)^{\frac{1}{2}}} \qquad (17)$$

where $z_0 = z - a$. The quantity z_0 is always positive. The formula (15) is true in the region between the two cones, and (17) inside the inner one.

Considering (15) first, it may be seen that the equipotential surfaces are all cones with a common apex at the forward end of the line, and that V increases from 0 on the outer cone to infinity at the axis. Deriving the electric force by (2), the result is

$$\mathbf{E} = \frac{\sigma}{2\pi c h\tan\theta}\,\frac{z\tan^2\theta.\mathbf{h}_1 + h\mathbf{k}}{(z^2\tan^2\theta - h^2)^{\frac{1}{2}}} \qquad (18)$$

where $\mathbf{k}$ and $\mathbf{h}_1$ are unit vectors along and transverse to the axis. The ratio of the transverse to the axial component is

$$\frac{\mathrm{E}_h}{\mathrm{E}_z} = \frac{z\tan^2\theta}{h}. \qquad (19)$$

Now z/h = constant is an equipotential surface. So, by (19), all the lines of force cut a given equipotential surface at the

Digitized by Google

same angle. Observe that for a given distance from the axis, the ratio of the transverse to the axial component increases in proportion to the distance from the apex. On the axis itself the axial component is

$$E_z = \frac{\sigma}{2\pi cz \tan^2 \theta'} \qquad (20)$$

varying inversely as the distance from the apex. Also, when h/z is small,

$$E_h = \frac{\sigma}{2\pi ch}. \qquad (21)$$

That is to say, the displacement at the axis is perpendicular thereto, spreading out all round from the electrified line precisely as if the line were at rest. But this does not continue, for all the displacement eventually goes to the conical boundary, or infinitely near. The turning round of the displacement takes place instantly at the apex, and more

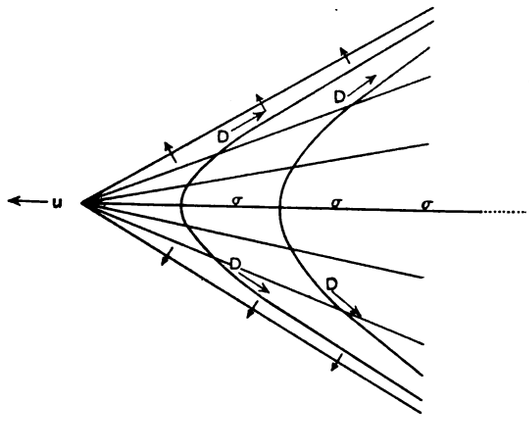

Fig. 26.

and more slowly the further away from it. As all the displacement ultimately concentrates about the boundary, the amount collected there tends to increase uniformly with z. At the same time, so does the surface of the cone. So the amount of displacement per unit area tends to become uniform, and since $H = VuD$, the state of affairs at the surface tends towards that of a pure electromagnetic wave, away from the apex, as the surface becomes more planar. A purely conical wave of the kind cannot exist alone. The lines of force are hyperbolas.

Fig. 26 will give some notion of the conical surfaces of potential and the hyperbolic lines of force, though, being done out of my head, I cannot vouch for the accuracy of shape of the curves.

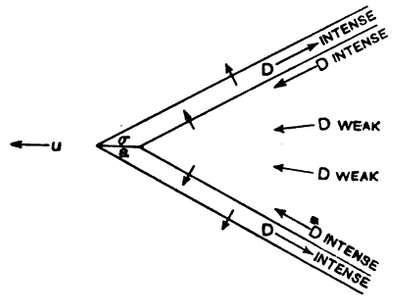

Fig. 27.

Now let the electrified line be of finite length a. We must then superpose on the field of force in Fig. 27, the exact negative copy of the same, but shifted through the distance a to the right. The result of the superposition is that in the overlapping region D tends to become radial, towards the moving charge, weak about the axis, and very intense at the conical surface; whilst outside, between the inner and outer cones, is an impure conical electromagnetic wave, in which D is very intense. Pushing things to the limit, reducing a to zero, and keeping the charge upon it finite, we come to the theory of the moving point charge, already given. It may seem to be much ado about nothing, but is there any easier way?

(*To be continued.*)

MR. A. W. HEAVISIDE'S PRESIDENTIAL ADDRESS TO THE NEWCASTLE-ON-TYNE LOCAL SECTION OF THE INSTITUTION OF ELECTRICAL ENGINEERS.*

I have thought that, as the establishment of a section of the Institution in the ancient city of Newcastle-on-Tyne earmarks both the place and the time, that perhaps it would not be altogether uninteresting to the members if an effort was made to locate in some degree the position held by the district, of which this city is the centre, in the electrical industry. To do this by way of historical introduction it is not necessary to go back to Thales, of Miletus, and his excited amber, but only to a more recent period which is scored all over with the honourable marks of discoveries and inventions which have mainly assisted in making electricity the servant of man.

As we all know, the pioneer industry is that of the electric telegraph. Like our venerable Queen, it came to the throne in 1837, where, similarly, it has reigned with ever-increasing beneficence ever since. Just look askance over one's shoulder down the back entry of time. There are always the shadowy forms, looming largely on the horizon, of Gray, an Englishman, who, in 1729, discovered the difference between conductors and insulators, using moistened packthread for the former and silk loops for the latter; of our great Anglo-American Franklin, who, in 1752, with his kite in the sky, conducted the lightning to the earth, thus establishing its identity with electricity; of Galvani and Volta, the eminent Italians, who, from 1786 to 1789, developed one source of electricity—namely, "the chemical battery." Oersted, the Dane, in 1819, deflected a magnetic needle by means of a current in a wire parallel with it, thus proving that currents and magnets have similar properties; whilst Ampère, the renowned Frenchman, in 1820, made another step by discovering that a suspended coil of wire carrying a current was a magnet. Then Italy, in the same year, in illustrious Arago, provided another link by temporarily magnetising soft iron during the presence of the current. Finally, Sturgeon, the sturdy Englishman, in 1825, made a last elemental step who by placing Arago's soft iron into Ampère's coil, producing the electromagnet of to-day, which, in conjunction with a needle or armature, is the basis of telegraphy and many other things.

The mental activity of the 12 years following, which gave a clearer grasp of the laws of electrical action, is marked by the mere mention of the names of such giants in science as Gauss, Weber, Coulomb, Faraday, Henry, Neuman, who also, in one way or another, contributed to the almost simultaneous invention of practical electric telegraphs in three great countries—viz., England, Germany, and the United States of America in the year 1837. June of that year gave the world Cooke and Wheatstone's needle telegraph; July, Steinheils' needle, bell and printed marks telegraphs; and October, Morse's marks embossed on paper. With many apologies to the names of the unnamed illustrious ones, I must conclude this stride over a century and endeavour to show Newcastle's place in telegraphy and kindred things.

In 1837, as I have said, a practical five-needle telegraph was invented (which was soon simplified to two needles only). This invention was slow of appreciation, for seven years elapsed before a joint stock company was established to exploit it. However, in 1844 the Electric Telegraph Co. started the combined railway and public service, and in two years their operations extended to this neighbourhood, where they established a double-needle circuit from Gateshead to York. At that time 13s. 4d. was charged for a message of 20 words from Gateshead to London viâ York. The basis of this charge needs to be placed on record. One penny per mile for the first 50 miles, one halfpenny per mile for the second 50 miles, and one farthing for every additional mile, with certain extras for porterage and addresses. In 1849 the high level bridge across the Tyne was completed, and with it came the establishment of an office on the Sandhill, about the site of Gosmas' restaurant. Newcastle's first direct connection with the metropolis was in 1851, when it was temporarily established with the first International Exhibition in Hyde Park. The double needle now began to give way to the single needle and the Bains' chemical recorder, which were succeeded by the Morse embosser in 1858.

In 1853-4 the Magnetic Telegraph Co., using Highton's single-needle and Bright's acoustic-bell system, a forecast of the American sounder, came to Newcastle with transmitting centres at Leeds and Carlisle, competitively reducing the before-named 13s. 4d. to 3s. as the Newcastle-London rate.

Another ten years, and 1864 saw the shilling or United Kingdom Telegraph Co., in local existence, using the Morse printer and the beautiful Hughes typewriter, invented in 1853-4-5, which brought Prof. Hughes honourable distinction in every civilised country but his own.

* Delivered at the Durham College of Physical Science, May 15th. Abstract.

Digitized by Google

But in 1867 a great jump was made. Up to this time the usual controlling force in all signalling by battery contact, or interruption, was the hand of the operator, which limited the speed of working on any wire to 30 or 40 words per minute at most. The Wheatstone automatic apparatus was first introduced for practical work in this country between Newcastle-on-Tyne and London; Edinburgh and Glasgow following after. Daily practical work is carried on with it at a normal speed of 330 words per minute on the local wires of this district, and between London and Birmingham, 600 per minute; of course, if duplexed, these figures become about 550 and 1,000 respectively.

In 1870, the Post Office acquired the telegraphs, and introduced universal shilling telegrams, followed in 1885 by sixpenny telegrams. By the kindness of Mr. T. Stevenson and Mr. A. Mellersh, the Post Office surveyors of this district, I am able to give the following figures of the traffic of this district for the year ending March 31, 1900:—

Telegrams forwarded.	Received.	Transmitted.	Total.
3,034,030	3,193,890	2,523,971	8,751,691

The first figure is the money-earning one and shows that, taking the population of the district at 2 000,000, rather more than 1½ messages per head of the population originate in the district per annum, but taking the forwarded and received, the traffic of the district is rather more than three per head of the population. The wires provided in the district by the engineers' department amount to 14,889 miles, carried along 1,794 miles of route; 287 post offices absorb 823 sets of telegraph apparatus, and 1,214 private offices absorb 1,418. The National Telephone Co.'s amount to *about* 5,000 exchange connections, using 6,657 miles of wire, serving 32 exchanges. The number of offices in direct communication with Newcastle at the present time equals 155, served by 104 wires, exclusive of wires that pass through Newcastle en route for other places. Of these 40 are for duplex working, 18 simplex, 18 single needle, 8 Wheatstone A B C, 7 Wheatstone automatic, 5 quadruplex, 1 diplex, and 7 for telephone and other uses. In addition there are eight lines to various submarine cables and a few spare lines.

To continue our story, of course, duplex and quadruplex telegraphy is largely employed. Gintl, in 1853, invented duplex telegraphy, but it did not come into practical use until Stearns applied a counter-kick condenser to it in 1873. O. Heaviside suggested quadruplex telegraphy which was developed by Edison and others, and was followed by the multiplex of La Cour and Delaney. In duplex telegraphy, as we all know, the outgoing current divides equally upon the apparatus nullifying local responses, consequently it is left free to respond to currents from the distant end only. Quadruplex is the addition to the latter of currents of two strengths with selective apparatus at each end which responds only to the current suited to it.

In multiplex telegraphy, six or more instruments are synchronously and successively connected to one wire with such short intervals between each connection that practically each operator has an independent use of the wire. Newcastle has not risen to the dignity of the use of this apparatus at present. The search for various methods of multiplex telegraphy led to the use of vibrating reeds of different responses. A reed may be a tongue of iron before an electromagnet. Here we have the magnetic telephone *in nubibus*. The tongue may respond to vocal vibrations, and be developed into a membrane of disc shape still more responsive. It is remarkable that there is a mysterious connection between the search for multiplex telegraphy and telephony, which just preceded the invention of the telephone.

It may be usefully mentioned here that in 1868 the importance of Newcastle-on-Tyne telegraphically was greatly increased in consequence of the Anglo-Danish, now Great Northern, Telegraph Co. commencing operations. Their first cable was laid in 1868, by Mr. R. S. Newall, between Newbiggin-by-the-Sea and Sondervig, on the west coast of Jutland, 335 nautical miles. The second cable was laid in 1873, between Newbiggin and Hirtsholson, on the same coast, 430 miles. The third cable was laid in 1880, between Newbiggin and Arendal, in Norway, 520 nautical miles; and their fourth and last cable was laid in 1890, between Newbiggin and Marstrand, in Sweden, 509¾ nautical miles. In addition, this company have two land lines to London, and one to Peterhead, in Scotland, in connection with another submarine cable to Norway.

The apparatus employed is one of remarkable delicacy (a first cousin to Lord Kelvin's siphon recorder, which is still more sensitive), called the "undulator"; indeed, so sensitive is the arrangement which works through the cables and the land lines to Scandinavia, at a normal speed of 80 words per minute simplex, and 120 duplex, that great care has to be taken to avoid lateral inductive effects.

The Commercial Cable Co. and the Anglo-American Cable Co. have each land wires to Newcastle to feed their cables.

Going back to 1859-60, at this time the Universal Private Telegraph Co. exploited the Wheatstone A B C telegraph for private conversation at a rental. This was introduced into Newcastle in 1863. Out of it developed the A B C exchange system, by which private circuits converging on a centre were joined together for conversational purposes. This was the forerunner of all telephone exchanges. Printing Court Building is the historic spot where this was first done in this country in 1864. Sir William Armstrong and Co., Thompson and Boyd, and Charles Mitchell and Co. were the first to keenly realise its advantages. This magneto-electric telegraph took 18 years to develop, from 1840 to 1858, and again the hand of Stroh helped Wheatstone. This instrument is really the baby of the alternating inductor dynamo of Mordey and others of to-day.

But in 1877 came the epoch-making telephone—the receiver perfect from the hand of Bell, our Anglo-American, at a bound (Alexander Graham Bell somehow stepped in front of Elisha Gray, who was first in the field). The instrument has appealed more powerfully to the mind of the thinker as a physical demonstrator of the existence of electrical vibrations than anything before and up to the time of Herz, in 1887. This instrument made the detection of long distance induction practical for telegraph purposes and preceded the no less extraordinary detector of Branly and others called the coherer. So great was the interest excited by the invention of the telephone, that in May, 1877, two of my staff, Mr. Frank Reid and Mr. W. R. Smith, needed no initiative to make the first telephones in this district from parts of the A B C telegraph.

Then Hughes, in 1878, crowned the telephonic edifice with the invention of the pencil microphone, nearly as we now have it, making a gift of it to the world, thus paying tribute to humanity as he has since done by bequeathing his great wealth to the London hospitals. Of course, from the first the days of the A B C were numbered, and the problem, how to get the telephone under control stared one in the face.

As it is with Newcastle we are mostly concerned in this address it behoves one to touch, alas, too lightly, in this lightning survey, on what was locally done as the result of the midnight oil. We can only stop to record one observation which, though it attracted little attention at the time, was eventually more far reaching in its consequences than any other. In May, 1877, a local circuit was made up of four lines converging on an Umschalter switch. When conversation was held between my office and three other rooms, better speech was obtained when all the telephones were in parallel than when all were in series. Why it was so, only revealed itself as time disclosed its importance.

On December 24, 1880, judgment was given that a telephone was a telegraph. This opened the door of the department for its exploitation. In 1881, a Post Office exchange was opened at Sunderland. It was joined up on the usual plan with the intermediate apparatus in sequence, upon double wire twisted loops, as first suggested by Prof. Hughes. The apparatus in sequence choked the speech, threw the line out of balance, let in lateral induction, undoing the benefit of Hughes' twist. Shift was made in this district, as all over the world, with this arrangement, its imperfections being condoned. With underground work it died at four miles length; by putting one intermediate on one side of the loop and another on the other side its life was resuscitated to eight miles of underground work, and there speech stopped dead. But, as had already been proved, there was one and one way only to secure telephonic speech unlimited as to distance and free from vagrant sounds. That way was hidden in the elemental principle of putting the intermediate apparatus in bridge across the line. Savants looked askance—it abrogated Ohm's law; why it short-circuited the line! However, its efficiency was drastically put to the proof by partial use in 1881; it survived the whips and scorns of time and was finally adopted *in toto*. Stockton was the first exchange entirely joined up in this manner, a new post office—involving new construction—was the opportunity. This exchange was opened on January 26, 1885. The kernel of the system is, that by putting apparatus of great impedence at the intermediate points, vocal high frequency telephonic undulations gave the short circuit the go-by, whilst low frequency call signal currents operated the signalling indicators at the bridges *con amore*.

The operating in the Post Office system is arranged so that overhearing on the part of the switch clerks is unnecessary, a system of automatic block signalling by means of needle deflections telling the operators all they need to know; hence all the conversations are heard only by those whose property they are—the principals in the transaction.

Telephone trunk wires were early introduced in this district, the first being between Newcastle and Sunderland in 1883. In October, 1896, when the National trunk wires became the property of the State, the Newcastle service had already reached 33, to which had to be added the National, giving a total of 68. Now they reach 72, and there is direct communication with 14 in number. If to this is added all the towns now served by telephone trunk wires, the total is 303. In the Tees-to-Tweed district, for the year ending March 31, the number of trunk calls reached 3,127,689. Local exchange calls reach about 12,000,000 per annum.

As already referred to, the telephone's detection of inductive effects at long distances is marked. This is the so-called wireless telegraphy of the electromagnetic order. It was always there—

Digitized by Google

most people knew of it from the days of Faraday and Henry in 1831; but what they did not know was its extent, which, after all, depends upon the force of the source, the delicacy of the detector, and to some extent on the opacity and transparency of the medium.

In the Newcastle battery room, as recorded in the *Journal* of the Society of Telegraph Engineers, Vol. X., p. 21, Jan. 26, 1881, in December, 1880, one had only to walk about the room with a telephone and a coil of wire to read the Morse signalling from every battery in use. This work was resumed in 1886 by a series of experiments, which had for their object four things: (1) At what distance from a primary parallel could these effects be detected on the telephone. (2) How much of the effect was conductive. (3) How much was induction. (4) Were all bodies transparent to them. On April 14 and 15, 1886, 14 years ago, on the Newcastle Town Moor, I proved, with 120 reversals per second and half an ampere of current, that it might be both, or whichever you pleased, inductive or conductive, dependent upon whether earth returns or insulated metallic returns were employed; also that where earth returns were used the earth could be tapped by driving two ends of four yards of wire with a telephone in circuit into the earth. It was also proved that with a secondary or with a primary only connected to earth at one point, static effects could be easily detected though diminished in loudness. Further, it was proved that if the distance from the primary was more than the length of the primary the effects diminished in loudness very rapidly.

From this time until August 15, 1886, the changes upon the above experiments were rung in many ways, always extending the distances, ending in Morse speaking across 40 miles of country, between Shap and Gretna on the west and Newcastle and Jedburgh on the east, produced by interrupting the vibrations with a Morse key. Up to this time the primary wires were usually single wires put to earth at each end, and the secondaries insulated squares or rectangles, and the difficulty was to get a space large enough to lay out insulated wires on the surface without exciting the hostility of the tenants of the Northumberland moors. However, Mr. Hugh Andrews, of Swarland Park, came to the rescue, and placed his estate at my disposal. Here it was, in the last week of August, 1886, that with two miles of insulated wire laid out as two squares of quarter mile sides, and a quarter of a mile apart, or half-mile centres, that articulate telephonic talk was inductively held between one square and the other. Hearable with closed circuits, difficult to hear, but present, with open circuits. Of course, this test was with undulatory currents of microscopic value and forms the highest testimony of the extraordinary sensitiveness of the telephone. This was followed up by telephonically speaking from the workings of Broomhill colliery to a triangle of insulated wire, three-quarters of a mile each side, laid roughly parallel over the colliery workings, the medium for the waves to travel being 360ft. of the crust of the earth. Of course, as every one knows, with the all-important addition of Evershed's call, this electromagnetic system has been developed and applied practically by Sir William H. Preece, and is in use between Flatholm and Lavernock in the Bristol Channel.

But in 1897-8-9 Marconi has, by combining the labours of Branly, Righi, Oliver Lodge and others, coupled with his own clever insight into the subject, signalled over great distances, truly without wires, for really what wire he does use may be considered as part of his electrostatic apparatus. In connection with the coherer which coheres in response to an electric flash, it is singular that Mr. Augustus Stroh has observed something akin in the adhesion of surfaces when traversed by an electric current (see *Journal* of Society of Electrical Engineers, Vol. IX., p. 182). And it is sad that, misguided by the savants, Prof. Hughes, the cruelly neglected scientist, did not go further in anticipating wireless telegraphy than as brought to light last year. Like Cavendish, it is a pity he did not publish his researches at the time.

We must now hurry forward to see where we stand with the other great electrical industries, better known than telegraphs and telephones in one sense, arising out of their control, not being that of the State, or of the monopolist, but everybody's business. Let us ask, What is Newcastle famous for in original work? Well, first we have Lord Armstrong's hydro-electrical frictional machine of 50 to 60 years ago, showing the electrification produced by steam rushing through an orifice, and then we have Lord Armstrong's *magnum opus* of 1897 on the "Electrical Movements in Air and Water."

Second in the order of date comes Joseph Wilson Swan, F.R.S., of Newcastle-on-Tyne, the inventor of the Swan lamp, which assumed practical form in the autumn of 1880. From the days of King, in 1845, to the days of Swan, in 1878-80, many tried their hands at getting light from incandescent platinum or carbon in vacua. But whilst all they did established the soundness of the principle, nothing they did brought more than disappointment from a practical point of view. Mr. Swan himself laboured and experimented with the incandescent lamp in the decade 1850-60 with like result. He used carbon strips in loops and spirals carbonised in Wallace's Forth Banks pottery kilns in crucibles filled with powdered charcoal, but the available mechanical air pumps gave a bad vacuum for such a purpose. Yet, at this early date, Mr. Swan had grasped the necessities of the case—a cheap source of electricity, an excellent filament, and a good vacuum. The filament was the crux of the problem, and as late as April 3, 1880, after much work in the meantime, taking four lamps as samples, their cold resistance was only 38, 45, 47, and 65 ohms, and 3½ amperes only made them red hot or a little more. But on June 15, 1880, Mr. Swan gave me the pleasure of testing one of 120 ohms, and another of 118 ohms resistance. This happier result was brought about by carbonising crotchet cotton—a true filament. [In the meantime it is interesting to note that Edison was more successful in his world-wide search for a vegetable fibre as a filament than Diogenes was in his search for an honest man. But then he did not use candles.] After this Mr. Swan made such progress that by the autumn Lord Armstrong's Craigside House was installed with 20 lamps; and on November 24, 1880, Mr. Swan brilliantly illuminated the auditorium of the Institution of Civil Engineers, in Great George-street, Westminster, to the delight of a distinguished audience of the members of the Institute of Telegraph Engineers and Electricians.

It is worthy of remark that Swan foreshadowed the Faure pasted plate (which Lord Kelvin brought in a box from Paris containing a million foot-pounds of energy). At his lecture before the Literary and Philosophical Society, of Newcastle-on-Tyne, on February 2, 1879, when exhibiting a crude lamp, he spoke of the need for storage and showed a modification of the Planté cell, in which there was the novel feature of spongy lead having been deposited around the frillings of the peroxide element previous to oxidation, to form what is now called positive element.

Swan's domestic lamp suggested a large incandescent lamp as a rival to the arc, and early in 1887 Mr. T. W. Edmondson, a disciple of Mr. Swan's, succeeded in making the Sunbeam lamp, of from 100 to 500, or even up to 2,000 c.p. It is deserving of honourable mention as a Tyneside development.

The Hon. Chas. F. Parsons has earned distinction to the district by his invention in 1876 and 1884 of the turbo-generator. For the horse-power developed, it is perhaps the lightest machine in existence, occupying little space, perfectly elastic, dancing in its bearings, and said to cost little to mechanically maintain. It is idle for me to attempt to describe what is done so much better by its inventor, who I shall now ask permission to quote:—

> The first condensing turbine of the radial flow type was of 200 H.P., and at a speed of 4,800 revs. per min. drove an alternator of 150 kw. output. It was tested by Prof. Ewing. With a steam pressure of 100lb., the steam being moderately superheated, and a vacuum of 28in. of mercury, the consumption was 27lb. per kilowatt-hour, which is equivalent to about 16lb. of steam per indicated horse-power. Turbine alternators and turbine dynamos of 2,500 H.P. are now in course of construction in England and the United States, and larger sizes are in prospect. A turbo-alternator manufactured at Heaton Works, Newcastle-on-Tyne, for the Corporation of Elberfield, in Germany, was tested a few days ago by a committee of experts from Germany, Prof. Ewing being also present. At the full load of 1,200 kw., and with a steam pressure of 130lb. at the engine, and 10°C. of superheat, the engine driving its own air pumps, the consumption of steam was found to be at the rate of 18·8lb. per kilowatt hour.

At the present time ten large towns in this district, including Newcastle, Gateshead, Sunderland, South Shields, Tynemouth, Wallsend, Hiddlesboro, Stockton, Darlington and West Hartlepool, have either electric power houses in active operation or in course of construction. But I cannot stop to say much of them, except the pioneer ones of Newcastle-on-Tyne. In this city we have two services, that of the Newcastle and District Electric Lighting Co., projected by the Hon. C. A. Parsons, late in 1888, and that of the Newcastle-on-Tyne Electric Supply Co., projected by Dr. Robert Spencer Watson, in 1881, but not brought to a practical issue until 1888.

Taking Parson's Co. first.—The original turbo-generators are employed at a speed of 4,800 revolutions, the later machines only 2,400 revolutions, with a pressure of 1,050 volts and a frequency of 80 periods. Last year the company generated 1,571,650 units, sold 963,622 units, and the peak reached 756 amperes upon an installation of 1,490,130 watts, the number of consumers being about 400.

The Newcastle-on-Tyne Electric Supply Co.'s plant is the very antithesis of that of its companion company. It is slow moving and heavy. Horizontal compound long-stroke Corliss engines of 70 to 80 revolutions and Mordey dynamos up to 150 kw. each. The engines, which are of Robey and Co.'s well-known make, and fitted with their trip expansion gear, have performed admirably. During the 11 year's working no main bearing cap on any engine has been lifted, and no new part has been supplied, excepting piston rings, and all the engines are now in first-rate working condition. The steam consumption may be said to average 16lb. with the low vacuum of under 20in., the larger units of course giving the best results. Similarly, the Mordey uniphase dynamos, 2,100 volts, have been equally successful. They are nearly self-regulating, the larger units being the most satisfactory. As is well known they are remarkably efficient, having the characteristic of steadiness under all loads. In 1899 the company generated 1,517,311 units for the supply of an installation of 1,924,680 watts, reaching a peak of 416 amperes upon a sale of 990,551 units, the number of consumers being nearly 1,000

Digitized by Google

Both companies use rubber cables, the "District" using a complete network of high tension single cables in iron pipes, and the "supply" a network of concentric cables in iron pipes. Rubber insulated cables, if not starved, and treated properly, either wholly concentric or wholly single pairs in a uniform atmosphere and a uniform mechanically protective environment, give little trouble. Both companies have cable 10 years old still doing excellent service. Both companies are developing direct low-tension services in congested places. Dr. Watson's company has two accumulator sub-stations, one in operation, another on the eve of practical employment.

Nowadays, when electric supply is an assured success, everyone can go to work with confidence, if only over-capitalisation is avoided. This is in the first degree the active danger of municipal undertakings governed by committees, all experts, of course. The need for dividends acts as the check in company undertakings—it tends to ensure both economy in capital, in production, and in maintenance. Production to serve a wide area of many needs assures continuity of load. This assures economy of production. An average of less than two hours' daily use of all the machinery in established pioneer stations brings 8 per cent. dividend. But suppose we build anew on the experience gained. Cease to put down what now may be considered toy machines all in a row and tobacco-pipe chimneys, jealously watched by vigilant smoke inspectors catching the specks upon sheets of white blotting paper. Emulate the courage of the Americans, the Swiss, and the Continent generally.

Of electric traction one can speak as eulogistically as of the bicycle. Happily now it is booming in this country, and one sighs with relief that at last our conservatism has been broken down, and we shall soon be as our colonies and other civilised nations are. Only build strongly; make a good, sightly, workmanlike structure, looking as if it fitted its purpose, then the cry of the æsthetic will cease and the cloud of the benighted disappear. I would like to express my unqualified condemnation of the extremely short-sighted policy of not starting with a double track right away in the busy towns of this district. It is only excusable when there is lack of width, and that is rare.

Another word, and this retrospect is done. The result of a circular I sent out to ascertain the number of persons employed on electrical work in this district gives the following approximate figures:—

Telegraphs and telephones	3,900
Electric supply companies	335
Manufacturers	2,400
Installers	219
Sundry employment	146
	7,000

ELECTRICITY WORKS ACCOUNTS.

The Metropolitan Electric Supply Company (Limited).

We are glad to be able to furnish our readers with an analysis of the accounts for the years 1898 and 1899 of this company, whose operations derive an unique interest from their magnitude.

A short history of this undertaking appeared in our description of the company's new works at Willesden on page 691 of our issue of March 9 last, so it is unnecessary here to introduce further remarks on that score.

As is well-known, in consequence of the delay in the completion of the Willesden station the concern has been considerably embarrassed during the period covered by the accounts with which we deal. This fact must, to a great extent, account for the somewhat unsatisfactory results which are shown. In 1899 the output advanced nearly 21·7 per cent., and the lamp connections about 15·6 per cent. A most satisfactory improvement is that shown in the load factor, which in 1899 was 12·6 per cent., as compared with 11·95 per cent. in 1898. Had it not been for these better conditions it is probable that the difficulties and forced rate of working necessitated by insufficient plant would have resulted in increased costs. As it is, and in the circumstances, we must say that the reduction of nearly 0·2d. in the aggregate costs is a commendable result. There is, however, plenty of room for further improvement in these costs, which are still at least 0·4d. per unit above what they should stand at in our opinion.

Running down the costs column attention is arrested at the high works, and more particularly, the generating costs which, in the aggregate, are quite 1d. per unit too high. It may be noticed that all the generating items are high except station wages. The fuel charges, as might be expected from the conditions under which the supply was met, is quite double the average.

We shall await with interest the results of the current year, showing the influence of the new station and more normal conditions of working upon the costs.

St. Pancras Vestry Electric Supply Works.

After the interposition of a year, in which this undertaking showed a falling off in the results obtained, we are glad to be able to record a resumption of the progress towards more economical working.

As may be gathered from the small table appended to these notes, the advance in the lamp connections during 1899, as well as in the output, has been most satisfactory—the former have advanced 22·5 per cent. and the latter—viz., the output—shows an increase over 1898 of 24 per cent.

Equally satisfactory is the reduction which has been effected in the costs. In 1898 the total costs, it may be remembered, showed a material increase on those of 1897. Last year, however, they fell to 2·64d. per unit—a good result; but, in view of the splendid load-factor of 15·8 per cent, coupled with the order of the output, a result still falling short by quite 0·5d. per unit of the possible.

The management and property charges, although showing an increase, are most satisfactory, but among the generating costs those of fuel and repairs and maintenance at the station are high.

There are some unusual expenses included in the costs, and it is only fair to note them. Thus there was £746 expended in re-arranging the public arc lighting mains and £1,348 alterations in connection with change of pressure to 220 volts. There was also £126 in respect of hire and erection of temporary plant.

Year ended Dec.	No. of consumers.	Current sold, not including arc lighting.		No. of lamps, &c., applied for.		
		At 3d. per unit.	At 4d., 5d., and 6d. per unit.	16 c.p. glow.	Arc.	Motors.
1892	172	...	£8,167	9,990	82	11
1893	238	£385	9,161	12,851	110	19

The Electrician.

The Oldest Electrical Journal (established as a weekly Journal 1861—1878

Published every Friday, Price Sixpence; Post Free, Sixpence-Halfpenny.
Editorial Publishing and Printing Offices,

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON

Telephone: 949 Holborn. *Telegrams:* "Electrician Newspaper London."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher "The Electrician," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "The Electrician" *Printing and Publishing Company, Limited, and be crossed "Coutts and Co."*

All Editorial letters to be addressed to The Editor.

All letters for insertion in "The Electrician," *or containing questions, must be accompanied by the name and address of the writer as evidence of good faith. No notice whatever is taken of anonymous communications.*

"The Electrician" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices, as above*

Subscription Rates.—The Rates for Subscriptions to "The Electrician" are as under:—

	Year	Half-Year	Quarter	
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.	Post free, payable in advance.
Postal Union ...	30s. 0d.	16s. 0d.	8s. 0d.	

New Volumes of "The Electrician" *commence in April and October.*

"The Electrician" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.** *This statement is guaranteed.*

Advertisement Rates, &c., forwarded on application to the Publisher.

Trade Advertisements *intended for the current issue must reach the Office not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday. Wrapper Advertisements by Wednesday morning.*

Official Announcements, Auctions, *and* Small Advertisements *accepted up to 6 p.m. on Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of The Electrician" *Printing and Publishing Company, Limited. The well-known* "Electrician" Series *of Standard Electrical Works at present consists of—*

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. Elton Young, M.I.E.E. Price 10s. 6d., post free; abroad 11s.

THE STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By Messrs. H. K. C. Fisher and J. C. H. Darby. Price 6s. net; abroad, 6s. 3d.

BIBLIOGRAPHY OF X-RAY LITERATURE AND RESEARCH. Edited by C. E. S. Phillips. With an introduction on the history of Crookes Tube and Röntgen Ray work, and a chapter giving "Practical Hints" on the subject.

THE POTENTIOMETER AND ITS ADJUNCTS. By W. C. Fisher. Price 6s., post free.

LOCALISATION OF FAULTS IN ELECTRIC LIGHT MAINS. By F. C. Raphael. Price 5s., post free.

MOTIVE POWER AND GEARING. By E. Tremlett Carter. Price 12s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. Wilkinson. Price 12s. 6d., post free.

ELECTRICAL LABORATORY NOTES AND FORMS (Elementary and Advanced). Arranged by Dr. J. A. Fleming, M.A., F.R.S. Printed particulars on application.

ELECTROMAGNETIC THEORY. By Oliver Heaviside. Vol. I. Price 12s. 6d., post free 13s. Vol. II. Price 12s. 6d.; post free, 13s.

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. Fleming. VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. New Edition. Price 12s. 6d., post free. VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. New Edition. 93 original illustrations, price 6s

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof J. A. Ewing, M.A. New edition. Price 10s. 6d., post free.

ELECTRIC MOTIVE POWER. By A. T. Snell. 10s. 6d. post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. George Gore. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. George Gore. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. Kennelly and H. D. Wilkinson. Price 6s. 6d., post free.

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. Weymouth. Price 7s. 6d. post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By Gilbert S. Ram. Price 7s. 6d., post free.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. Geipel and H. M. Kilgour. Price 7s. 6d. net, post free 7s. 9d., abroad 8s.; large-paper edition, 12s. 6d., post free. New edition in the press.

"THE ELECTRICIAN" PRIMERS. In Two Vols. Paper covers, 2s., post free 2s. 2d. each; strong cloth 2s. 6d., post free 2s. 8d. each. Single Primers 2d., post free 2½d.

WIRELESS TELEGRAPHY: Signalling across Space without Wires by Electric Waves. By Dr. O. J. Lodge. New Edition. Price 5s. net.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING, ELECTRIC TRACTION, TELEGRAPHS, TELEPHONES, &c. A. C. Curtis-Hayward, B.A. To January, 1900. Price 3s. 6d., post free.

CARBON MAKING FOR ALL ELECTRICAL PURPOSES. By Francis Jehl. Price 10s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d., post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. Beaumont. Price 3s. 6d., post free.

FULL CATALOGUE POST FREE ON APPLICATION.

"ELECTRICIAN" SERIES FORTHCOMING BOOKS.

THE ELECTRIC ARC.—By Mrs. Ayrton. This work is in the press, and will contain an historical sketch of the early experiments on the electric arc, as well as the important results of recent research.

PRIMARY BATTERIES.—A work on this subject will shortly be published bringing the theory and practice of the Primary Battery up to date. The book will be fully illustrated.

SECONDARY BATTERIES.—By E. J. Wade. Fully illustrated. The Author in this work will deal briefly with the theory and fully with the chemistry, design, construction and manufacture of secondary batteries or accumulators.

"THE ELECTRICIAN" WIREMAN'S POCKET-BOOK.—Edited by F. C. Raphael. "The Electrician" Company will shortly publish a valuable pocket-book for the use of those engaged in wiring work, both external and internal.

THE TELEPHONE.—By Dane Sinclair and F. C. Raphael.

SPECIAL NOTICE.

NOW READY.—Vol. XLIV. of "The Electrician" (960 pages), bound in strong cloth. Price 17s. 6d., post free 18s. 6d. Also ready, Cases for binding. Price 2s., by post 2s. 3d.

A complete set of "The Electrician" (1878-1900) can now be supplied. These sets are very scarce, and early application should be made.

ELECTRIC TRACTION UNDER BRITISH CONDITIONS.

We conclude this week our reprint of the Paper recently read before the Institution of Electrical Engineers, by Mr. H. M. Sayers, on "Distributing Systems of Electric Traction under British Conditions"; and we give a short abstract of the not-particularly-important discussion this Paper evoked. The title of Mr. Sayers' Paper ends with a noteworthy reservation. The phrase "under British conditions" as applied to electric traction is significant of much; only those who know the conditions of electric traction in the United States and elsewhere abroad can say how much. Several factors exist to produce these special conditions in this country. Chief among them, of course, are the wisely-framed regulations of the Board of Trade; but there is also the important factor of cultured public taste to be reckoned with, in the designing and erection of British electric tramways; again, the engineers who have been responsible for this work have been able to draw upon a reserve of national experience in the design and erection of electric supply works unequalled by that of any other country. Thus it has come to pass that the United Kingdom, which for a long time lagged behind all the rest of the civilised world in regard to electric traction, is now setting an example to all the world in solid and thorough work. Nowhere outside the United Kingdom can better examples of electric traction be found than exist in our principal electrically-equipped cities—a fact which, by the way, may be pressed upon the attention of globe-trotting municipal delegates.

Into the question as to whether the Board of Trade conditions and regulations ought or ought not to be revised we do not at present propose to enter. In the main it must be admitted by even those who would entirely revise them that under their influence a healthy growth of electric traction has taken place. Mr. Sayers' Paper deals with these conditions as they stand, and he discusses therein the various systems of distribution of power for electric traction which are compatible with these conditions. It is possible, however, to acquiesce in the Board of Trade regulations and the general conditions of British electric traction *in toto*, and yet to disagree with many of Mr. Sayers' conclusions. The key-

Digitized by Google

note of these objections might be found in Mr. JENKIN'S remark, during the discussion, that the Paper deals with "a particular case." It is possible, of course, so to deal with a particular case that the conclusions derived therefrom shall be of general applicability. On the other hand, a particular case is often an isolated case, an exception to the general rule, an instance in which deductions "go by contraries." We think Mr. SAYERS' Paper falls under the second rather than the first category; his deductions as to the relative merits of various systems of distribution being inapplicable to the general problem. Take, as an instance, his remarkable advocacy of multiple power stations in preference to a central power station for the entire tramway system. It would be a fair inference to draw from Mr. SAYERS' Paper that the correct method is to place a generating station at every four miles or so along the electric line, letting this supply merely over a radius of two miles. Curiously enough, on the very day Mr. SAYERS advanced this extraordinary postulate in electric traction design, a number of eminent electrical engineers and others were endeavouring to convince Parliament that the most economical and best way of distributing electric power for traction, lighting and public supply is to have one or two large generating stations for each area as large as an entire county. Are we to be told that this has nothing to do with Mr. SAYERS' "particular case"? Are we to hear in Parliamentary committee rooms that the conditions of modern electrical supply demand wider scope, ampler fields of action and greater variety in the character of the demand; while, on the selfsame day, the Institution of Electrical Engineers presents a Paper to the world, in which one of the fundamental conditions of a system of British electric tramways or railways is stated to be the erection of a separate power station at every few miles? Mr. SAYERS, indeed, is out of harmony with the march of electrical engineering; his conclusions belong to a bygone stage of electrical progress. While he is troubled about how to eke out the volts along a few miles of trolley line, polyphase engineers are designing and building power stations that are capable of doing all the traction and other electrical work for 20 miles or more around them.

We have attacked Mr. SAYERS' most vital position, for upon the decision as to the number and distribution of the power stations turns the whole question discussed in his Paper. Of the rest of the Paper it must be said that there is much instructive and useful information, especially as to matters of detail. It is, perhaps, the misfortune of the critic that he sometimes finds more useful work in exposing and rebutting errors than in enlarging upon points of merit. If we have devoted the greater part of our space in this leading article to criticism rather than to praise, it is not because Mr. SAYERS' Paper does not contain many passages which are worthy of the thankful attention of electric traction engineers. A man of wide experience in electrical affairs, Mr. SAYERS has embodied usefully the results of his past work. Though the broad lines of design Mr. SAYERS lays down are not such as we think the future will justify, it is, nevertheless, certain that the mass of details in Mr. SAYERS' design upon those debatable lines are *sans reproche*. Even if, to take another example, his interpretation of KELVIN'S law of economy is open to criticism, he would be the last to pledge himself to the dictates of his mathematics where they appeared to conflict with common sense or mature practical experience. Distributing systems may be calculated on paper by rigid rules, but the rigidity must generally be greatly relaxed before they can be transferred from paper to *terra firma*.

PRACTICAL EXAMPLES OF SIMULTANEOUS TESTING, AS APPLIED TO FAULT LOCALISATION IN SUBMARINE CABLES.

BY C. W. SCHAEFER.

Apropos of editorial remarks in connection with certain modifications of methods of fault localisation by simultaneous tests, which up to the time of my describing them* had merely been proved a practical success by experimental tests on artificial faults, opportunities have since occurred enabling me to supply some of the desired numerical data obtained in actual work, aptly illustrating the feasibility and power of these theoretically perfect methods.

The first occasion on which one of the tests was applied practically, happened to be an unusually interesting case of a rare type of fault, which, perhaps, is unparalleled in the annals of cable testing, and may be classed as one of those somewhat doubted "Phantom" faults, only two of which had previously come under my observation. It occurred on an important cable with no duplicate section at hand by which a loop test could be attempted, whilst duplex working was rendered impossible by reason of the fault's variability, which could not be compensated for by placing a leak suitably on the artificial line. It was therefore of importance that it should be removed.

Several attempts were made to localise it, but the fault neither remained at any sufficiently low nor constant value to allow of a single test being taken by any of the usual methods. At times its resistance fell as low as 800 ohms, but merely for a fraction of a second, whilst from that value it would leap up in a single bound to thousands of ohms, and frequently to megohms, thus apparently vanishing from the cable, the normal insulation of which was some six megohms. Its general condition was such that even with exceedingly small currents there was no possibility of getting it down to localisable limits both as regards its resistance and the length of time it remained low, the matter being further complicated by the length of the section—viz., 812 nauts, the copper resistance and inductive capacity being respectively 8,315 ohms, and approximately 250 microfarads.

Off and on, attempts extended over a period of more than three months; but the actual time that the fault was under observation and test amounted to 44 hours in the aggregate, during which time it was not possible to get even one single overlap test.

Finally, after having made cuts in order to ascertain the extreme limits of its position, and having gathered from experience that even under the smallest practicable currents the fault, if low, generally sealed very rapidly to some megohms, an attempt was made to localise it during its brief period of lowness by a simultaneous test. And, further, to minimise the margin of error, a position was selected for cutting in such that the fault was between the ship and the nearer station, that is to say, the copper resistance of the line actually was 2,285 ohms.

Neither of the terminals being provided with a milammeter, prior to the ship's departure, a test was taken of the station's 30 cell Leclanché battery, and its internal resistance found to be 75 ohms; but in common with other Leclanchés, especially those of the porous pot type, its polarisation was great and rapid. Since also the station was not acquainted with the modification of Kempe's loss of current test, which necessitated an earth current correction being made to the scale zero bridge reading, it was pre-arranged that the readings ashore were to be taken to earth current zero, whilst at the ship the received currents were observed on a Weston milammeter, having a coefficient of 4·85 divisions per milliampere, together with an auxiliary milammeter composed of a shunted Sullivan galvanometer, for which a preliminary calculation had been made, the coefficient being 52·7 divisions per milliampere.

To increase the shunting effect of the fault, which was known to be within 1,100 ohms, or 107 nauts, from the ship, a resistance was added, which together with the milammeters amounted to 504·5 ohms.

* *The Electrician*, Oct. 29, 1897.

Digitized by Google

It was arranged with the station to test with 80 Leclanchés and 1,000/1,000 ratio for 10 minutes, the first five being taken with 504·5 ohms in circuit on board, whilst during the the second period of five minutes that resistance was increased to 1,004 ohms.

The fault, however, did not remain low nor steady during the latter period, and the observation was therefore limited to within the first *five* minutes, the result being as follows:—

Resistance observed to E.C. zero by shore.

2587·5 ohms (corrected).

Current observed on milammeters on board.

Weston	Galvanometer
35·5 to 36 (with roll of ship)	430
4·35	52·7
= 8·15 to 8·27 milliamperes.	= 8·16 milliamperes.

Shortly after this test the fault was found to have sealed to over 2·5 megohms, and neither potentials as high as could be used with discretion, nor extremely small ones, would reduce its resistance, which, with the exception of brief "kicks" down to 6,000 ohms, and on one occasion as low as 700 ohms, generally kept at its high figure of 2·5 megohms.

The opportunity was taken advantage of, while the fault was high, to determine the correct copper resistance (2,285 ohms), and also to get a test of the station's battery by observations on board ship upon a basis of which the limits of the fault's distance were assigned. The process was as follows: The shore station was instructed to take a scale zero bridge reading under the same conditions of battery power and bridge ratio as previously used, keeping his current on for five minutes, whilst the received current on board afforded a means of determining the percentage of battery polarisation and also its effective E.M.F. The station's bridge reading was 2,252 ohms, whilst the current received on board fell from $\frac{55}{4\cdot35} = 12\cdot63$ milliamperes to $\frac{51}{4\cdot35} = 11\cdot7$ milliamperes in about 3½ min.; therefore the *effective received current* appeared to fall about 7·3 per cent., or the battery E.M.F. from

$$0\cdot01263\ (2\times75+1000+2252) = 42\cdot97 \text{ volts}$$

to $$0\cdot0117\ (2\times75+1000+2252) = 39\cdot8 \text{ volts.}$$

This indicated also that polarisation had come into play by the time the received current could be observed, for the normal E.M.F. of the battery should have been about $80\times1\cdot45 = 43\cdot5$ volts.

Allowing that during the shorter applications of the current in taking the earth current zero test, the polarisation was less, or say at least 8½ per cent. on the free potential of the battery, the current entering the cable would be $\frac{42000}{3737} =$ 11·24 milliamperes, and therefore, using the formula

$$x = \left(\frac{nA_1 - L}{n-1}\right),$$

where $$n = \frac{11\cdot24}{8\cdot16} = 1\cdot377,$$

$$A_1 = 2587\cdot5,$$

$$L = 2285 + 504\cdot5 = 2789\cdot5,$$

$$x = \frac{(1\cdot377\times2587\cdot5) - 2789\cdot5}{1\cdot377-1} = 2053\cdot5 \text{ ohms,}$$

which was accepted as the superior limit of the fault's distance from the shore station, whilst its apparent resistance during the test was $f = \left(\frac{n}{n-1}\right)(A_1 - x)$,

or $$\frac{1\cdot377}{1\cdot377-1}(2587\cdot5 - 2053\cdot5) = 1952 \text{ ohms.}$$

For the inferior limit an allowance of 7½ per cent. on th full battery E.M.F. was made, and consequently the current entering line would be $\frac{40200}{3737} = 10\cdot76$ milliamperes, from which we get

$$x = \left\{\frac{\left(\frac{10\cdot76}{8\cdot16}\times2587\cdot5\right) - 2789\cdot5}{\frac{10\cdot76}{8\cdot16}-1}\right\} = 1962 \text{ ohms from shore,}$$

and the apparent resistance of the fault in this case

$$\frac{1\cdot318}{1\cdot318-1}(2587\cdot5 - 1962) = 2592 \text{ ohms.}$$

Absolutely no other test could be taken as a check upon this solitary observation, and although somewhat diffident as to the reliability of this method, hitherto untried in actual practical work, the result was considered good enough to work upon, and the cable was subsequently hooked 2,065 ohms from shore. Here again the fault behaved in its usual peculiar manner and corroborative tests being quite impossible, there was no alternative but to pick up to the inside limit indicated by the test.

When 650 fathoms had been recovered, the joint resistance through the fault and dielectric intervening between ship and shore increased to 16 megohms, and it was suspected that the fault had come into the tank. Accordingly the cable was cut, and after waiting for eight hours, a drop to 8½ megohms on the sea end indicated that it had not yet been removed. Picking up was therefore continued until a splice had been reached 1,958 ohms from shore, where the cable was again cut, the fault being then found in the tank portion. A dielectric resistance test shorewards gave a result 30 megohms, showing that at its highest value, when submerged in 240 fathoms of water, the fault must have had a resistance of over 30 megohms.

Even when in the tank, the behaviour was much the same as when submerged, and it was only by keeping a continuous watch for some hours that in one of its momentary falls in resistance a loop test placed the fault 15·6 ohms from the top end, that is to say 1978·6 ohms from shore; practically at the inside position of the accepted limits, proving that the shore stations battery must have almost attained its maximum polarisation during the earth current zero test.

Whilst in the tank, potentials as high as 140 volts were tried without in any way tending to open up the fault. On stripping the faulty portion, a small fragment of a hard substance resembling a portion of a tooth was found embedded in the gutta-percha, the dimensions of which were approximately 2·5mm. long, 1mm. wide, and about 0·8mm. in thickness. This projected externally to the gutta-percha about 0·3mm., and around this projection the jute adhered firmly, there being no brass tape on the core. There was no visible defect on the sheathing, and, it was perhaps, merely a factory fault, which, however, did not assert itself until some six years after submersion. On removal of this substance the resistance of the fault was generally 35,000 ohms, and fell to a minimum of 1,200 ohms.

In describing this, perhaps, the first practical application of this improved method of simultaneous testing, I think I am justified in saying that this fault could not have been localised within the above limits by any other of the known methods applicable to a single cable. Considering also that the conditions were rendered the more doubtful by the mere fact that a milammeter was not available ashore (although the vanishing fault was to a certain extent generous in affording a means of accurately determining the copper resistance of the line, and also of ascertaining the effective E.M.F. of the shore battery, and, consequently, the limits of current entering the cable), this instance is, I hope, sufficiently important to prove the practicability of this method.

Still more recently, other opportunities have arisen in which this particular method of simultaneous localisation has been resorted to with complete success and a minimum expenditure of time, permitting faults to be localised with no skilled assistance at the shore station other than that required for the correct reading of the milammeter at preconcerted intervals.

The following example I quote as being a typical one, in which, in spite of circumstances that prevented confirmatory tests being taken without endangering the cable whilst the ship was hanging on to it, a mean of seven consecutive readings gave a distance 11·8 ohms short of the real one, a second fault of much higher resistance nearer the ship being, perhaps, wholly responsible for this error.

Before leaving to remove a series of faults from a section, a milammeter was left ashore through which the cable was

Digitized by Google

earthed during the tests, the routine being as follows: A chronograph was started on board at the instant a "dot" was received from the shore, and at each consecutive minute from that signal simultaneous readings were taken until the cessation of the testing current signified that results were to be communicated. The readings on board were balanced to instrument zero with an even ratio in the bridge, whilst the milammeter being placed in the battery circuit registered twice the amount of current entering line. The earth current was so small that it was negligible.

Ship.				Shore.	L = 1,473 ohms.		
Time: Minutes.	Current (milliamperes): Entering fork.	Current (milliamperes): Entering line.	Resistance observed to instrument zero (A_1).	Current (milliamperes).	Ratio of currents (n).	x.	f.
1	20·9	10·45	827	23·25 ÷ 4·35 = 5·33	1·96	154·7	1,373
2	20·2	10·10	910	25·00 ÷ 4·35 = 5·73	1·76	172·4	1,708
3	19·9	9·95	929	25·25 ÷ 4·35 = 5·80	1·715	169·2	1,822
4	24·9	12·45	921	31·50 ÷ 4·35 = 7·23	1·72	156·9	1,825
5	24·6	12·30	920	31·50 ÷ 4·35 = 7·23	1·70	131·4	1,915
6	25·0	12·50	890	30·75 ÷ 4·35 = 7·07	1·76	132·2	1,755
7	25·2	12·60	877	30·00 ÷ 4·35 = 6·90	1·826	155·7	1,595

Mean value of x = 153·2 ohms.

It is a good plan when taking a set of readings to vary the current, as was done at the end of the third minute. This fulfils the double purpose of finding the range of current best suited to the fault under test and of serving as a check on the other observations. It is interesting, too, to observe that the somewhat large range of the "apparent" distance indicated the existence of the second fault. This "wandering" is to be expected even with a single fault that is at all variable, for the impossibility of absolute simultaneity would cause incontrollable disturbances which could only be eliminated by taking the mean of a few sets with various currents.

The following set, with another and still more variable fault shows the manner in which the earth current correction is applied. The resistance of the line, including the milammeter, was estimated at 1,319 ohms.

Constant.—1 Leclanché cell (1·45 volt) through high resistance (H.R.), approximately 20,000 ohms, gave 567 divisions ∴391 divisions per 1,000 millivolts.

Preliminary earth current deflection (e) = 20 divs. *left* = 51 millivolts (additive).

Ship.						Shore.	L = 1,319 ohms.		
Time: Minutes.	Current (milliamp.): Thro' fork.	Current (milliamp.): To line (c).	Reading A corrected for temp.	Earth current corr'ctn $\left(\frac{e}{c}\right)$	Reading corrected (A_1)	Current received (milliamperes).	Ratio of currents (n).	x.	f.
			ohms.	ohms.	ohms.			ohms.	ohms.
1	21·9	10·95	490*	4·6	494·6	16·75 + 4·35 = 3·85	2·85	48·6	687
2	21·4	10·7	524	4·7	528·7	18·25 ÷ 4·35 = 4·2	2·55	18·7	1,437
3	21·8	10·9	475	4·7	479·7	16·75 ÷ 4·35 = 3·85	2·83	21·3	1,010
4	22·4	11·2	430	4·5	434·5	15·75 ÷ 4·35 = 3·61	3·10	13·3	804
5	22·6	11·3	390*	4·5	394·5	15·0 ÷ 4·35 = 3·45	3·28	neg.	—
6	23·0	11·5	372	4·4	376·4	14·0 ÷ 4·35 = 3·215	3·58	18·3	585

* Approximately.

Ignoring the first test, which was observed at the most variable period, and also the fifth, which works out about 11 ohms negative, the mean value of x is nearly 18 ohms, the true distance proving to be 12·5 ohms.

The mean swings of deflections were accepted as balance for the bridge readings, and, in both cases cited above, these swings were at times almost across scale! Whenever possible it is, of course, always desirable that, as a further check, the order of the test should be reversed—that is to say, the current should be applied from the other end of the cable, a resistance being added to the line at the terminal taking readings of c alone if it happens to be very close to the fault, in order that its shunting effect may be made adequately great.

Before observing the preliminary earth current, it is advisable to earth the cable for one minute *at least*, more especially if the Morse has to be used instead of mirror for signalling purposes; and, if possible, the simultaneous readings should be taken every 15 or 30 seconds, so as to minimise the error that would be occasioned by a change of earth current.

I believe that the test above exemplified will eventually prove itself more frequently serviceable than the simultaneous null-method bridge test which, besides requiring a little more skill in execution, depends upon observations of current as well as bridge readings at both ends of the cable, although in certain cases the latter test can claim superiority.

I may state, finally, that in the instances above quoted, the method adopted was the only one practicable excepting "Blavier's"; and it is, perhaps, needless to point out the economy of time and material that may be expected when the adoption of the milammeter method becomes universal.

THE CALCULATION OF DISTRIBUTING SYSTEMS OF ELECTRIC TRACTION UNDER BRITISH CONDITIONS.*

BY H. M. SAYERS.

(*Concluded from page 182*).

Obviously, the calculations above described will only give correct results for the distribution of traffic and current assumed. Such assumptions can only approximate to average working conditions, and it is only prudent to allow a considerable margin on the upper side in assuming the traffic, for growth and other obvious possibilities. Again, the feeding points so found may not be the best practically. It would be better, for example, to feed the track at a junction, connecting the feeder to all the diverging roads, than at a near point indicated by calculation, which should result in excessive current density in the rails of one road. Such excessive density may damage rails and possibly cause local damage to pipes near by. The best density of current for track feeders is determined exactly as for trolley feeders, giving the wasted watts their proper rate as "boosted watts." Unboosted track feeders are of no commercial value, as Mr. Parshall distinctly showed in the Paper before referred to. In our example, the density for boosted feeders has already been shown to be 306 per square inch, giving a drop of 13·75 volts per mile run. From these figures the feeder sections and losses, and sizes of boosters, can be readily applied to suit the feeding points found in the manner above explained. The detailed calculation for track feeders is given in Appendix No. 4, and all track feeders needed on this system are shown in diagram B. The list of them is as follows:—

No.	Route.	Length.	Current.	Sections, sq. in.	Tons, Cu.	Value.	Drop.	Loss in watts.
1	T E'wards	2·97	120	0·39	10·5	£1,585	41·6	5,000
2	T W'wards	4·00	273	0·89	32·3	4,877	60·24	17,000
3	T to J	2·15	127·5	0·415	8·1	1,223	32·4	4,200
		9·12			50·9	£7,685		26,200

Boosters to a total capacity of, say, 36 kw. would be needed, costing, say, £15 per kw. or £540. Annual charges at 15 per cent. on these amount to £81. As before, the interest on the mains is rather less than the cost of power, the assistance of the rails coming in to reduce it. We then get on the track side:—

Loss in feeders, 26·2 k.w., worth annually	£600
Interest on cables, 7 per cent. on £7,685	538
Charges on boosters	81
	£1,219

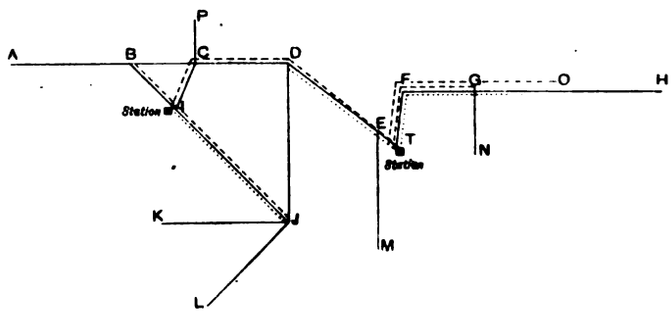
Adding this to the cost on trolley side, £1,291, we get a total of £2,510. This equals 0·266d. per unit delivered to the cars making its cost there 1·016d.; and the total annual generating and distribution costs, as far as here considered, £9,936. There will be 25·645 miles of cable laid in 12·025 miles of trenching, weighing 104·15 tons, to the value of £15,853, in addition to the cost of laying them. Boosters will cost £740. The electrical efficiency of the whole system will be about 427·5/499 = 86 per cent. or a trifle higher. These figures show very strongly that a single low tension station for this system is very expensive in first cost of distribution plant, cables alone costing £32 per kilowatt capacity. The regulation as to potential drop in rails puts direct supply out of court as soon as the distances and traffic exceed certain moderate figures. It seems, however, that a modification in track construction, using continuous girder supports under the rails and dispensing with concrete and setts between them, should be a logical consequence of electrical

* Paper read before the Institution of Electrical Engineers, May 3rd.

Digitized by Google

traction, and that the conductivity of the track might thus be largely increased and bonding made much more permanent without much increase in construction costs. The difficulty now experienced at the joints of tram rails should disappear, and the life of the road be greatly increased. For electric traction purposes the granite between the rails is entirely unnecessary. Municipal tramway engineers might give this a trial; companies cannot do so in the present state of the law.

The first alternative to this costly single station system is the provision of a second generating station (diagram C), still using low-tension plant and distribution, and retaining T as one station, as the plan indicates that T is fairly well placed for the eastern part of the system. The junction I appears to be a good position, consequently the second station is assumed to be at that point. The arrangements east of T will remain unaltered. On the west, the two stations ought to supply power up to equidistant points measured along the tracks. The cross-country conductor TJ will not be needed, and though useful for enabling one station to assist the other in case of breakdown (a valuable advantage of multiplicity of stations), it will not be further considered here. The equidistant point on the route TDCI is 0·1 mile west of D, and on the route TDJI it is 1·68 miles south of D. The western station I will then supply all the cars between C and D and two out of the five between D and J; its load will then be 24 cars or 360 amperes, leaving T to provide for 33 cars or 495 amperes. The cost of generating



Trolley feeders – – – – – – Track Feeders
Limits as in Diagram B.

DIAGRAM C.—Low Tension, Two Stations.

and the most economical current density are taken at the same figures as for the single station. T has to supply westward the current for 14 cars, or 210 amperes as follows:—

60 amperes for branch EM, average distance 1·35 miles.					
105	ditto	TD,	ditto	1·17	do
45	ditto	DJ,	ditto	3·20	do

The two cars on branch FD are taken as before, as supplied via F. At the voltage drop of 15·8 per mile the total watts lost come to 5,500. East of T they are as before, 8,250 unboosted, 720 boosted. I has to supply 360 amperes as follows:—

30 amperes to branch DJ, average distance 3·3 miles.					
45	ditto	IJ,	ditto	1·4	do.
30	ditto	JK,	ditto	3·9	do.
15	ditto	JL,	ditto	3·8	do.
90	ditto	CD,	ditto	1·6	do.
30	ditto	CP,	ditto	0·8	do.
30	ditto	ICB,	ditto	1·35	do.
45	ditto	IBC,	ditto	0·7	do.
45	ditto	AB,	ditto	2·1	do.

The total watts lost come to 10,602. No provision is made in this for boosting, as only a little current is carried beyond the 50-volt drop limit, and under the circumstances that drop is unlikely to be exceeded in actual work. The copper sections, weights, and values needed will be as follows:—

Direct Feeders.

Line.	Length, miles.	Amperes, mean.	Section, Cu., sq. in.	Tons, Cu.	Value.
TF	0·9	187·5	0·531	4·35	£655
FG	1·25	120	0·342	3·56	533
TE	0·35	203	0·579	1·84	278
ED	2·00	98	0·277	5·02	758
IB	1·1	75	0·213	2·13	323
IC	0·9	142	0·404	3·30	498
IJ	2·8	98	0·277	7·01	1,058
CD	1·65	45	0·129	1·93	292
	10·95			29·14	£4,400

Boosted.

TO ... 3·8/14·75 ... 45 ... 0·134 ... 4·63 ... £699

Total 33·77 tons, value £5,099.

The cost of distribution on the trolley side is thus:—

Loss in direct feeders, 24·37 kw., worth annually	£411
Loss in boosted feeders, 0·72 kw., worth annually.....	16
Annual charge on boosters	6
Interest on direct feeders, 7 per cent. £4,400	308
Interest on boosted feeders, 7 per cent. £699	49
	—£796

This works out per unit delivered to the cars £796/2,340,000 = 0·81d., or total 0·831d., disregarding losses in returns. The track feeder east of T remains as before, and that west of T must tap the rails at D and carry 120 amperes, have a section of 0·391 sq. in. with a drop of 35·5 volts, needing a booster of 4,260 watts. From I one feeder to J carrying 43 amperes section 0·140 sq. in. drop 42·2 volts, will require a booster for 2,600 watts. No other will be needed, though a small addition to the service and load on the line between A and D would call for a feeder to B or C. The track feeders are then as follows:—

Line.	Miles.	Amperes	Section sq. in.	Tons, Cu.	Value.	Drop.	Loss watts.
T E'wards	2·97	120	0·39	10·5	£1,585	41·6	5,000
T W'wards	2·35	120	0·39	8·33	1,258	35·5	4,260
ISE.....	2·8	43	0·14	3·55	536	42·2	1,815
	8·12			22·33	£3,379		11,075

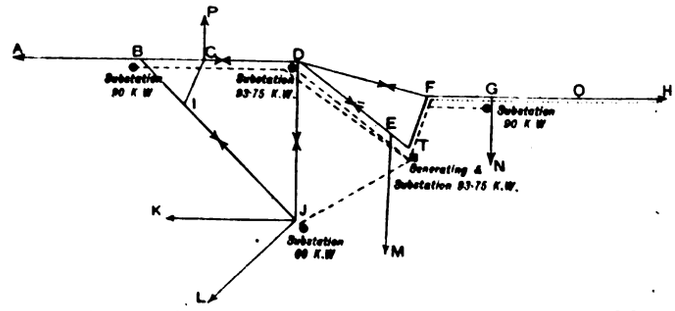
Boosters to a capacity of, say, 18 kw. will be needed, costing £270. The cost of distribution on track side will thus be:—

Loss in feeders, 11·075 kw. worth annually	£252
Interest on cables, 7 per cent. on £3,379	236
Charges on boosters, 15 per cent. on £270	41
	——£529

and the total cost of distribution:—

Trolley side.....	£796
Track side	529
	——£1,325

equal to 0·135d. per unit, or a total of 0·885d. The capital cost of the cables will be £8,478, their length 22·87 miles, laid in 13·85 miles



High tension 3-phase feeders – – – – – – No low tension feeders needed.
Arrow heads indicate supply limits from sub-stations.

DIAGRAM D.—High Tension, One Generating Station and Five Transforming Stations, one being at Generating Station.

of trenching, and the cost of boosters £310. The cost of the cables amounts to £18 per kilowatt full load output, and the efficiency about

427·5/468 = 91·5 per cent.

The annual costs of generation and distribution as above qualified will be £8,751, or £1,185 less than with the single station, and this sum is the margin out of which the extra working and capital charges due to the use of a second station have to be met. Unless such extra charges exceed the saving in distribution, the two-station system will be the more economical. A sound knowledge of the local conditions should enable a fair estimate to be made, but it is not susceptible of calculation on general principles. The incidental advantages of the multiple-station system should be carefully considered in each case, and if the calculable operating costs are about equal, those advantages should turn the scale in its favour.

Multiphase Distribution.—Assume one station, at T (diagram D), generating plant to give three-phase current at 2,500 volts. Using three-wire mains, the current per conductor will be

Kw. $1{,}000/2{,}500 \times \sqrt{3} = (\text{Kw. } 0\,23)$ amperes.

The cables will be of the three-core twisted or equivalent type, and on this account as well as the larger amount of insulating material needed, their cost per ton of copper will be higher. The depreciation will also be at a higher rate. First, because the scrap price will be a lower proportion of total value; and, second, because high-tension cables certainly suffer more from faults than those under low tension. Therefore R is taken at 9 per cent., p at £208, the other values remaining as before—

$$t^2 = 9 \times 58{\cdot}45 \times 208 \times 0{\cdot}045 \times 9{\cdot}1/100 = 448 \text{ and } T = 21{\cdot}2,$$

the density $21{\cdot}2/0{\cdot}045 = 470$ per sq. in., and the drop per mile 21·2 volts. The loss in any three-wire three-phase conductor will be $3\,C \times 21{\cdot}2$ per mile, where C is the current as given above for the

Digitized by Google

load transmitted, so that the loss per kilowatt delivered to the cables will be 0·69 × 21·2 = 14·62 watts per mile, or 1·46 per cent. per mile. Transformers will be required at G, T, D, J, and B, the output needed being as follows :—

From G	.....	12 cars	.....	90 kw.
„ T	.....	12·5 „	.....	93·75 kw.
„ D	.....	12·5 „	.....	93·75 kw.
„ J	.....	8·0 „	.....	60·0 kw.
„ B	.....	22·0 „	.....	90·0 kw.
	Total	57·0 cars		427·5 kw.

These loads are allocated on the simple consideration that each transformer should supply half-way to its neighbour in each direction, and represent the energy delivered to the cars. Loss on the low-tension side has to be added to get the gross output, which may be taken at 450 kw. Hence at four of the five stations 100 kw. sets, and at the other a 65kw. or 70 kw. set would suit. But allowance must be made for spares and for unusual demands due to local pressure or bunching of traffic. Whether it would be better to put down two 100 kw. or three 50 kw. sets at the larger stations should in every case be determined on comparison of the cost of the different sized sets with their switch gear, the probabilities of exceptional traffic, and other fairly obvious considerations. It might well happen that the two larger sets would cost little more to instal than the three small ones, and that the extra flexibility would be well worth the cost. Assuming, however, that the three-set plan is adopted, it will be necessary to instal transformers to a total capacity of 705 kw.

The high-tension feeders to these sub-stations will be as follows, assuming a full-load efficiency of transformation of 85 per cent., or rather a constant loss during operation at the rate of 15 per cent. of the rated capacity, and 2,500 volts pressure :—

Line.	Miles.	Amperes.	Sec. (sq. in.).	Tons, Cu.	Value.	Loss in watts
TG	2·15	3 × 24·2	3 × 0·051	2·98	£620	3,307
TD	2·35	3 × 25	3 × 0·053	3·27	680	3,736
TJ	2·15	3 × 16·1	3 × 0·034	1·95	406	2·201
TB	5·25	3 × 24·2	3 × 0·051	7·30	1,518	8,080
	11·90			15·50	£3,224	17,324

The loss in the transformers on the above assumption will be 15 per cent. × 470 = 70·5 kw. With this disposition of sub-stations no track feeders are needed, and secondary trolley feeders can also be dispensed with, as the trolley wires of usual size will not drop more than 10 volts average all over the system, the worst point being H, where the drop will be 32 volts. The trolley wires leading east of G, from T to E, and B to C, will be somewhat heavily loaded, and for reliability of service it might be well to use some auxiliary feeders, or heavier trolley wires on these sections, but this will not be necessary for distribution efficiency.

The distribution losses will then be :—

	kw.	
In high-tension cables	17·3	
In transformers	70·5	
In trolley wire	8·55	
		96·35

and the generating plant must be able to give out 524 kw. Overall efficiency of the system being thus 427·5/524 = 81 per cent. nearly. This is a little higher than Mr. Parshall's figures for Dublin. No addition has been made to the cable losses for power factor being less than unity, and it appears probable on the rather scanty information obtainable in this country that full justice is done to current practice in the above result. To obtain the annual cost of this distribution, proper charges on the transformers, including attendance, have to be estimated. This again is not easy, for the prices of such plant are are not readily obtainable, but for the present purpose market prices are not essential. There is good authority for the statement that for smaller sizes than 200 kw. motor generators perform better than static transformers and rotary transformers, therefore motor generators are assumed in the following figures :—

Motor generators to capacity of 705 kw. at £15 per kilowatt with switch-gear	£10,575
Four sub-stations and sites at £80 each	320
	£10,895
Interest, depreciation and repairs, 12½ per cent. on £10,575 and 2½ per cent. on £320	1,329
Attention to each set, say 3s. per week or £7. 16s. per annum, 15 sets	117
Oil, brushes, and sundries, say £2. 10s. per annum, per set ...	37
Total per annum	£1,483

The distribution costs then work out as follows :—

High-tension conductors, C²R loss value 17,324/58 45	£295	
Interest on cables (cost £3,224)	290	
Loss in transformers 70,500/58·45	1,205	
Loss in trolley wire, 8,550 at 48·5 per £1	176	
Interest and attention and stores on transformers ...	1,483	
		£3,449

This sum amounts to 0·352d. per unit delivered to the cars, making the cost of the power there 1·102d. per unit, or £10,875 annually. This is 0·217d. per unit, or £2,124 per annum in excess of the two-station direct supply, and £939 in excess of the one-station direct supply, as will be shown by the tabulated results below.

Obviously a high-tension station cannot generate at a lower cost per unit than a low-tension station on the same site, but the result of this investigation goes to show that if in the neighbourhood a site exists with such advantages that the cost per unit of the power generated there and delivered to T, or equal point, will be under 0·53d., instead of 0·75d., there will be an advantage in using the transformer system. In other words, this calculation shows what saving in generation costs is required to justify the use of a transformer system and a high-tension station.

The capital expenditure is not much reduced, as the total for cables and transformers amounts to £14,119, which lies between the costs of cables and boosters in the two low-tension systems discussed. There would be also a considerable saving in cable-laying expenses, due to the lighter cables and smaller number of ways needed. This point and the difference between the capital outlay in the stations are foreign to the present subject, but must of course be keenly studied in practical designing. It should, however, be noted that the load factor is of great importance, and that the assumed conditions are rather more favourable to a transforming system than the conditions usually found in practice, for the reason that the losses in transformers are largely independent of the load, and that sufficient transformer capacity must be kept in use to provide for the maximum demands during any given period. The device of dividing into small sets and putting them in as needed cannot be carried far for several reasons. Hence the losses are more nearly those due to the maximum than to the average load over any given period. Cable losses, on the other hand, vary with—and as the square of—the actual load, consequently a poor load factor tells much more against the efficiency of transformers than of cables.

The small proportion of the total losses due to the high-tension transmission indicates the small effect of distance on the overall efficiency, so that the radius within which the advantages of a specially favourable position for a generating station may be utilised is not severely limited. For lines on which multiphase motors and the consequent increased number of overhead wires are practicable, it is apparent that the advantages of this system are very great. Only static step down transformers being required, the overall efficiency can be kept high, and attendance at sub-station made very trifling. This is hardly a live subject in this country yet, but the economies of distribution on such a system can be worked out on the same lines as here put forward when occasion shall arise and the regulations to be complied with shall be known.

The principal figures in the three schemes above worked out are here tabulated for comparison :—

—	Low tension.		High tension.
	1 station.	2 stations.	1 station.
Distribution costs, annual	£2,510	£1,325	£3,449
Ditto per unit at car	0·266d.	0·135d.	0·352d.
Generation and distribution, annual ..	£9,936	£8,751	£10,875
Ditto per unit at cars.....	1·016	0·885d.	1·102
First cost cables and transformers ...	£16,593	£8,788	£14,119
Miles of cables	25·64	22·87	11·90
Miles of trenching	12·025	13·85	9·55

APPENDIX No. I.—Calculation of Most Economical Current Density.

Rate of ohmic loss. C^2r watts, where C = current in amperes and r = resistance in ohms.

Rate of interest and depreciation loss in £ sterling per annum. = (R/100) pma + constant. Where R = rate per cent. per annum of interest and depreciation ; p = price in £ per ton of copper in the form of cable, m = tons of copper per mile of conductor of 1 sq. in. cross section ; a = cross-section of conductor in square inches, so that $m\,a$ = tons of copper per mile; and the constant represents such costs of laying and other expenses as are practically dependent only upon the length of cable laid and independent of its size. To add these losses they must be equated for definite conditions of load and period of use. For this purpose, assume the period to be one year ; the load to be steady and lasting for a certain fraction of every day = $h/24$. A certain cost per Board of Trade unit delivered to the conductor = n pence. Then £1 per annum is the cost of $240/n$ Board of Trade units wasted per annum, and the rate of waste in watts which gives such a loss is $240{,}000/(hn \times 365)$, or $657{\cdot}5/hn$. Call this w. It is the number of watts which, wasted during all the working hours in a year, will cost £1. Then (R/100) $wpma$ is the interest cost of the cable expressed as a loss in watts during working hours, and the total rate of cost of distributing the current C through the cable is $y = C^2r + (R/100)\,wpma$. The resistance of the conductor obviously affects the value of the two quantities making up the total loss in opposite ways, and the problem is to find the value of r which makes y least. Consider a cable of one mile in length. If the resistance of one mile of copper conductor of 1 sq. in. cross-section is 0·045 w, then $a = 0{\cdot}045/r$, and the second item of the total

Digitized by Google

cost $= Rwpm\ 0{\cdot}045/100r$. Since this has been equated to a rate of loss in watts, it may be written

$$C_2^2r^2/r = t^2/r, \text{ where } t = C_2r,$$

C_2 being such a current as would produce the required loss in watts on traversing the resistance r. We then get

$$y = C^2r + t^2/r, \text{ whence } dy/dr = C^2 - t^2/r^2,$$

and this a minimum when

$$C^2 = t_2/r^2 \text{ or } r = t/C.$$

This is the Kelvin law, since when this is the case $C_2 = C$, and the two items of cost representing ohmic loss and interest are equal.

The most economical current density therefore is

$$C/a = t/0{\cdot}045, \text{ where } t = \sqrt{(Rwpm0{\cdot}045)/100},$$

and the most economical rate of voltage drop is t volts per mile. If the load is not steady, but varies in a known way, then C^2 = the mean square of the current in respect to time, and C = the square root of that. In the expression for t^2, $Rpm/100$ is the annual cost of one mile of cable of 1 sq. in. copper section—*i.e.*, of 9·1 tons copper weight. Then $Rpmw\ 0{\cdot}045/100$ may be written $0{\cdot}41\ Rpw/100$ or $0{\cdot}0041\ Rpw$, and the most economical current density written

$$C/a = t/0{\cdot}045 = \sqrt{0{\cdot}0041\ Rpw}/0{\cdot}045,$$

and a table of such densities for various values of the product Rpw can be readily formed.

APPENDIX No. II.—Examples and Tables of most Economical Current Density.

Symbols as in Appendix No. I.

$$C/a = t/0{\cdot}045 = \sqrt{0{\cdot}0041\ Rpw}/0{\cdot}045.$$

R = percentage interest charge on cables.

p = cost of one ton of copper in form of cable.

$w = 657{\cdot}5/hn$, where h = equivalent full load hours of use per day, and n = cost in pence of one Board of Trade unit.

For example, let $\left.\begin{matrix} R = 9 \\ p = £200 \end{matrix}\right\} Rp = 1800$

$\left.\begin{matrix} h = 12 \\ n = 0{\cdot}8d. \end{matrix}\right\} hn = 9{\cdot}6$

$w = 657{\cdot}5/9{\cdot}6 = 68{\cdot}49,$

then $t^2 = 1{,}800 \times 68{\cdot}49 \times 0{\cdot}0041 = 505{\cdot}4$, and $t = 22{\cdot}5$ – drop in volts per mile $C/a = 22{\cdot}5/0{\cdot}045 = 500$ amperes per square inch. The equality of ohmic and interest losses is readily shown. One mile of cable of 1 sq. in. section will cost £200 × 9·1 = £1,820, and the interest on it at 9 per cent. will be £164, while the ohmic loss will be $500 \times 22{\cdot}5 = 1{,}125$ watts, worth also £164 per annum: to the nearest £1 in each case. Tables for varying values of Rp and w are convenient, in the following form:—

$Rp = 1{,}200.$

w.	t = drop per mile.	Best density.
40	14	312
50	15·7	362
60	17·2	383

$Rp = 1{,}500.$

40	15·7	362
50	17·6	392
60	19·2	427

$Rp = 1{,}800.$

40	17·2	383
50	19·2	427
60	21·1	469

or a table giving values of t and best density for values of the product. Rpw may be readily made and used.

APPENDIX No. III.—Calculations for "Boosted" Feeders.

The only special factor in these is the correct value of w. Such value should take into account the transformation loss in the booster, and the annual charges on that machine referred to its output. If n is the cost of a Board of Trade unit at the main switchboard, and the efficiency of the booster at its average working load is x/100, the transformed units will cost $(100/x)\ n$ in energy alone. Again, if the machine cost £a per annum in interest and depreciation, and £b per annum for attention and stores consumed per unit of average working output, these charges will add to the cost of the energy $(a + b)\ 240/365 \times h$ in pence per Board of Trade unit, the value of w will then be

$$w = \frac{240{,}000}{\{365h \times (n100)/x\} + 240(a + b)}$$

For example, if a booster cost £15 per kilowatt output, and 12 per cent. is charged for interest, &c., and if it costs 10s. per annum for attention and stores, these costs amount to £2·3, or $a + b = 2{\cdot}3$, then, if the set is in service 15 hours per day $(a + b)\ 240/365\ h = 2{\cdot}3 \times 240\ 0{\cdot}5475 = 0{\cdot}11$ pence.

With $n = 0{\cdot}75$d. and efficiency 75 per cent., the cost per unit transformed becomes $(0{\cdot}75 \times 1{\cdot}33) + 0{\cdot}11 = 1{\cdot}11$ pence; and $w = 240/(1{\cdot}11 \times 5{\cdot}475) = 39{\cdot}5$ The values of w so found should be used in calculating the best density of current in the "boosted" feeders. It must be noticed that where boosters are used, as on trolley feeders, to keep the drop within certain limits, the boosters have only to supply the difference between the permitted drop and that which occurs in the feeders, and the current density found as here explained is that which should prevail in the corresponding distance beyond the point at which an unboosted feeder will give the limiting drop. Hence the total drop in the boosted feeder should be the sum of the limit, and that in the length beyond at the density here found, and the actual section of the feeder should be such as to give that drop on the actual feeder length. Thus, if the limiting drop is 50 volts, and that is given by an unboosted feeder 3 miles in length; whilst a boosted feeder is 4½ miles long, and should drop 15 volts in the 1½ miles excess, the proper uniform density in the whole 4½ miles should be such as to give 65 volts drop. Unless supply is given much beyond the limiting drop distance the decrease in current density as compared with that found for direct feeders will not be large. In track feeders, however, the "boosted" density is practically correct, as the permissible drop is always much exceeded. The best density for secondary feeders supplied from transformers is found in the same way as for track feeders.

APPENDIX No. IV.—Calculation for Track Feeder, East of T.

Rail resistance, 0·0289 w per mile.
Drop allowed, 5 volts.
Amperes × miles constant for 5 volts = 173.
Current per car, 15 amperes. Cars passing in pairs.

From T Eastwards.

Cars.		Amp. miles. Product.	Sum.
T to F, 5 cars, 0·9 mile.	1st pair	30 × 0·3 = 9	
	2nd pair	30 × 0·6 = 18	
	1 at F	15 × 0·9 = 13·5	
	2 on line DF	30 × 0·9 = 27	67·5
F to G, 4 cars, 1·25 miles.	1st pair	30 × 1·21 = 36·3	103·8
	2nd pair	30 × 1·83 = 54·9	158·7
	2 on line NG	30 × 2·15 = 64·5	223·2

As the sum is brought over the constant by the current flowing in at G from branch NG, G should be a point of change of direction. The product of amperes × miles on branch NG is 15 × 1·1 = 16·5. This added to the 158·7 at G = 175·2, a little over the limit. Hence the whole of the 30 amperes from branch NG should flow east, and the integral of ampere miles from G to feeding point should be 173 – 16·5 = 156·5, to keep N at 5 volts.

Then from G Eastwards. Section GO, 4 cars.

1·5 miles long. Current flowing east 30 amperes from branch NG.

Cars.	Amp. miles. Product.	Sum.
At G	16·5	
G to 1st pair	30 × 0·375 = 11·25	27·75
1st pair to 2nd pair	60 × 0·75 = 45·00	72·75
2nd pair to O	90 × 0·375 = 33·75	106·50

H being terminus, and only 2 cars between H and O, it is obvious that feeding point should be west of O, so sum westwards from H. H to O 1·7miles.

Cars.	Amp. miles. Product.	Sum.
1st pair to O	30 × 0·85 = 25·5	
O to 2nd pair GO	30 × 0·375 = 11·25	36·75
2nd to 1st pair GO	60 × 0·75 = 45·00	81·00

Feeding point will thus be between the 1st and 2nd pair of cars east of G. It should be exactly 0·825 miles east of G. The product from this point will be 54·75 to the terminus H and to N, corresponding to 1·58 volts drop. Hence the feeding point may be 3·42 volts above earth.

The track feeder will have to carry back 120 amperes, and be 2·975 miles long. Section should be 0·39 sq. in., and the drop in it will be 15·06 × 2·975 = 45 volts. But as its end may be 3·42 volts above earth, the booster will have to give only 41·58 volts, and have an output of 41·58 × 120 = 5,000 watts, say.

Track Feeder No. 2.

From T Westwards.—It is obvious to inspection that some current should return viâ D and some viâ J. The dividing points should be those at equal distance from T by each route. On the branch DJ this point is practically at the centre of its length, hence half the total current is taken as flowing each way. On the circuit TDCIJT it is very close to the junction I. Hence the current returning by J will be half that on the branch DJ, and the whole of that on branches from J to I, K and L respectively, making altogether 8·5 × 15 = 127·5 amperes, which gives at once the section of the track feeder from T to J. It also follows that the potentials of points D and J should be kept equal. Find feeding points, &c., as before. T to D, 7 cars 2·35 miles. Branch CM, 4 cars = 60 amperes at 0·35 miles from T. Assume 1 car at D, the other 6 in pairs at 0·59, 1·18 and 1·77 miles respectively from T.

Current Eastwards towards T.

Cars.	Amp. miles. Product.	Sum.
T to C	60 × 0·35 = 21·00	
T to 1st pair	30 × 0·59 = 17·70	38·7
T to 2nd pair	30 × 1·18 = 35·40	74·1
T to 3rd pair	30 × 1·77 = 53·10	127·2
T to D	15 × 2·35 = 35·25	162·45 = 4·7 V.
T to O, part current from branch DJ	4·4 × 2·35 = 10·5	173

giving 5 volts at D.

Current Westwards from D.

D to C, 1·65 miles, 6 cars, passing at 0·41, 0·82, 1·23 miles from D, 33 amperes from branch DJ also—

Cars.	Amp. miles. Product.	Sum.
D to 1st pair	33 × 0·41 = 13·53	
1st to 2nd pair	63 × 0·41 = 25·83	
2nd to 3rd pair	93 × 0·41 = 38·13	
3rd to C	123 × 0·41 = 50·43	127·92 at C

Count back from A to find equal point.

A to B, 2 miles, 3 cars, assume 1 at A, 2 in middle.

Digitized by Google

CURRENT EASTWARDS FROM A.

Cars.	Amp. miles. Product.	Sum.
A to 1st pair	15 × 1 = 15	
1st pair to B	45 × 1 = 45	60

B to C, 1·1 miles, 2 cars, assume in middle, current of one car from branch BJ. Continue summing from A.

Cars.	Amp. miles.	Product.	Sum.
B to middle	60 × 0·55 = 33		
Middle to C	90 × 0·55 = 49·5	.....	142·5 at C.

This indicates feeding-point a little west of C, but as 60 amperes more enter from branches north and south of C, and C is the meeting place of four tracks, it is clearly the proper place for the feeder to tap the rails. If this point be kept at earth potential, A, the point farthest from T will be at 4·1 volts above earth. The feeder will be 4 miles long, have to carry 273 amperes back, have a section of 0·89 sq. in., will drop 4 × 15·06 = 60 24 volts, and booster must give 273 × 60·24 = 16,445, say 17,000 watts.

TRACK FEEDER No. 3.

Inspection of the diagram suffices to show that J must be the feeding point for this. The greatest drop thence will be on branch JK, 2·2 miles long with two cars. Assume one at K and one half way, then ampere miles KJ will be 41·25 or 1·2 volts. J must then not be more than 3·8 volts above earth. This is lower than D, so that more than the half current on line JD will return by the feeder viâ J. *Per contra* part of the current from branch IJ will go viâ IC. The assumed distribution could be obtained by splitting the feeder at J, and connecting the branches at proper points on the three lines JL, JK, JI. No practical advantage would result, as in working the load on each feeder is regulated to keep the pilot wire indications within proper limits, by control of the booster E.M.F., and it is quite certain that the actual load and its distribution will vary widely and rapidly in any given case from any assumed distribution, consequently in a network requiring a number of track feeders it is sufficient to ensure that they shall be provided of needful section and number to enable the P.D. on the rails to be kept within limit, and refined investigation of the current distribution is likely to be labour lost. Hence No. 3 feeder may be safely taken as tapping rails at J. It will be 2·15 miles long, carry 127·5 amperes, have a section of 0·415 sq. in., drop 32·4 volts, and require a booster to give 32·4 × 127 5 = 4,130, say 4,200 watts.

DISCUSSION.

Prof. ANDREW JAMIESON said he was at Cape Town the other day, and had found a drop of 30 volts between the end of the line and the power house.

Mr. A. M. TAYLOR said that polyphase working, which had been referred to in the last section of the Paper, was especially interesting from the fact that it would be necessary to consider in the immediate future whether light railways, as well as tramways, could be worked economically by this system. As it had occurred to him that its advocates would probably try to reduce Mr. Sayers' figure for the distribution costs—viz., 0·352d. per unit delivered to the car—he had calculated how much it would be possible to do so. Some might claim that reduction could be made in the losses in the motor generators; but even supposing, for the sake of argument, an efficiency of 92½ per cent. were taken (which would be an extremely high value and could only hold where static transformers and rotary converters were employed, and hardly then), this item would only be changed to 0·292d., which was something like one-third of a penny on every unit turned out by the sub-station. In the case of a long, straight line, with a comparatively infrequent service, the conditions would be quite different. He considered Mr. Sayers had favoured the multiphase system by allowing such a small amount for attendance at the sub-stations—viz., 3s. per week per set, or 9s. per week per sub-station—and he did not quite see how it was going to be managed. On the other hand, as he had already mentioned, a rather high value for the losses in the motor generators was taken by the author. The results obtained by him (Mr. Taylor) in the matter of the cost of distribution on a multiphase system were, under the most favourable conditions for the same size system as that considered by Mr. Sayers, about 0·292d., and under the least favourable conditions, about 0·378d. Taking the case, already mentioned, of a long, straight line of single track, with a sub-station working three miles on either side of it—say with a half-hour service—they would have 20,000 motor car miles per annum for each mile of line, or a total of 120,000 car miles per annum. The cost of distribution came to 0·56d., or with a 20-minute service 0·44d. for every unit delivered to the car, and whether this was a practicable amount to have to pay as an extra item for the cost of distribution was, of course, questionable. There were two statements in the early part of the Paper which were rather important—viz., that the distance to which it was possible to distribute economically was not limited by the density of the traffic, and that the cheaper the cost of power the *shorter* the range of economical distribution. The first point seemed a little strange, and one might think of the gradients and how they would affect the distance. But it seemed that these did not affect the limit at all. The reason of the second statement was that Mr. Sayers' formula led him direct to a particular current density for each case, which was higher as the cost of power was cheaper. Hence, having fixed his drop at 50 volts for every case, as a limit, that limit was reached at a less distance when the density was higher—*i.e.*, when the cost of power was cheaper. His last point referred to boosters, and in this connection he could not understand Mr. Sayers' figures. It appeared that he proposed to allow 3·16 miles to go unboosted, and then to use a booster to supply the part beyond that limit and only boost for the voltage that was beyond that 3·16 miles. He thought Mr. Sayers would see on reflection that it would be necessary to boost for *double* the number of volts he proposed—the 50-volt limit of drop having been reached at 3·16 miles. The drop in the trolley wires, or distributors, working back from the point of connection with the feeders, must be taken into account as well as the drop in the feeder itself.

Mr. EUSTACE THOMAS considered Mr. Sayers' Paper of considerable interest and importance in that it strongly advocated the laying out of feeder systems with a view to securing the greatest possible economy in working. As a general rule the first cost of the cables has been the determining factor, and as a result, very few lines in the country are working under the conditions of Lord Kelvin's law. Two years ago he had worked out a modified method of applying Lord Kelvin's law which had brought the whole question straight to the cable price list and gave more accurate results than other methods in that it took into account the variation in the cost of insulation as well as in the cost of copper. The method will be found to have the further advantage of being very rapid in application. Let C = current conductor has to carry, L = length of conductor in feet, £ = cost of B.T.U. in £, p_1 = cost in £ of one mile of a given size of cable. p_2 = cost in £ of one mile of the next size of cable *larger*. H = number of hours per annum the current C will flow, r_1 = resistance of one size of conductor per mile, r_2 = resistance of next size of conductor per mile, I = rate of interest allowed on capital, allowing for maintenance and depreciation.

(1) Resistance of first conductor $= r_1 \times L \div 5{,}280$,

and watts lost $= C^2 r_1 L \div 5{,}280$;

$\therefore$ B.T.U. lost per year $= \dfrac{C^2 r_1 L \times H}{1{,}000 \times 5{,}280}$,

$\therefore$ Cost of energy wasted $= \dfrac{C^2 r_1 LH \times £}{1{,}000 \times 5{,}280}$

Similarly for r_2 cable $= \dfrac{C^2 r_2 LH \times £}{1{,}000 \times 5{,}280}$;

$\therefore$ Saving by using r_2 cable $= (r_1 - r_2) \times (C^2 LH \times £)/(5{,}280 \times 1{,}000)$

(2) *Cost of Cable.*

Cost of one mile $= p_1$.

,, L feet $= p_1 L/5{,}280$.

Annual cost for interest, &c. $= p_1 L/5{,}280 \times I$.

Similarly per second cable:—

Annual cost for interest $= p_2 LI/5{,}280$.

$\therefore$ Extra annual expense through using second cable $= (p_2 - p_1) LI/5{,}280$.

The two cables will be equally economical, and be the best possible as regards economy of transmission, if above saving = corresponding increased expenditure.

i.e., if $(r_1 - r_2) C^2 LH \times £/1{,}000 \times 5{,}280 = \{(p_2 - p_1) LI\}/5{,}280$,

i.e., if $$\frac{p_2 - p_1}{r_1 - r_2} = \frac{C^2 LH \times £}{LI \times 1{,}000} = \frac{C^2 \times H \times £}{1{,}000 \times I}.$$

Now the ratio on the left can be embodied in a price list, since it is dependent on the cable only. The following is an example of this:—

Size.	r.	p. $\dfrac{p_2 - p_1}{r_1 - r_2}$.
19/16	0·7013	270
19/15	0·5565	330 > 406
19/14	0·4507	396 > 624
19/13	0·3409	520 > 1,130
19/12	0·2656	650 > 1,885

Hence for the above conditions we determine the value of

$$\frac{C^2 H \times £}{I \times 1{,}000}.$$

Find the nearest value in the table in the last column and select the corresponding cable as the most economical.

It is important to note that the cost of producing *extra* energy only should be considered. This ought to be considerably less than the average cost of producing the whole energy supplied by the station. Also the amount reckoned for interest would be 2 or 3 per cent. perhaps in the case of a Corporation borrowing money at low rates, while it might be 5 to 10 per cent. in the case of a company paying the corresponding dividend. It is to be noted particularly that in most cases cables cannot be worked at their most economical current density as this would result, where long and short feeders are used in the same system, in a great variation of voltage at the feeding points. If Mr. Sayers' assumptions are examined it will be found that the shortest feeder would have a drop of only about five volts, whereas the next longer feeders would have a drop of about 30 to 37 volts. In actual fact the current density in the short feeder would be increased considerably above Mr. Sayers' figures, as with the feeders shown it would not be possible to section the line completely. This would probably make some variation in the feeding system advantageously, and this would affect the comparative cost of this system.

Mr. B. JENKIN was of the opinion that this Paper should not be taken as in any way comparing the relative merits of a system worked by one station as against a system worked by two stations or comparing again these systems with multiphase systems. It was extremely interesting as a calculation of a *particular case*, but they could not generalise in any way from it, and this should be borne in mind very closely. Another point was Mr. Sayers' statement that feeders should be run to separate sections, and it would be interesting if the author gave more information on this matter. It appeared to him that it must depend entirely upon the

Digitized by Google

number of cars on the line and the nature of the line. Very likely with few cars it would be possible to use the copper very much more economically by connecting the feeders to a number of places on the trolley wire, otherwise there might be several sections lying idle without any car getting current from them, whereas if the feeders were connected in parallel with the trolley wire as he had just suggested, the whole of the copper would always be usefully employed.

Mr. E K. SCOTT said that the multiphase system would work very much better if Mr. Sayers had taken, instead of a primary voltage of 2,500, about double that.

Mr. JAMES SWINBURNE said he always had some fear, in reading a Paper like this, that accuracy was sacrificed for simplicity of calculation. Kelvin's law was Kelvin's law as long as it was simple, but as soon as real circumstances were dealt with, there were all sorts of things which came in. The first and most obvious difficulty in applying anything at all like Kelvin's law was the question of insulation. Of course the insulation did not vary as the cost of the copper, and it went up with the pressure and so on, so that this gave at once one large departure. Another question of cost which he did not think traction people had considered sufficiently, was the eating of pipes. Of course generally the pipes were not theirs, and the cost need not be included. He did not know whether the tramway companies fully understood the English law on this question. As he understood it, it seemed that a private individual was liable to damages if he ate anybody else's pipes but that by working under an Act of Parliament they could eat as many pipes as they liked provided they took the ordinary precautions and did not eat more pipes than they could help. The Board of Trade was supposed to keep down the consumption of pipes, and generally, if they followed the Board of Trade, they were supposed to get off scot free. But speaking seriously, he thought this question of the corrosion of pipes was going to be one of the greatest difficulties in electric traction work, and there was one method which had not been sufficiently considered in this country, viz., the three-wire system. The ordinary three-wire system was applied to almost every case except electric traction. The Board of Trade rules at present would not allow the three-wire system at all, and if it was to be used they would have to be altered. The question had been discussed before their Institution once or twice, but perhaps the real reason that it had not been adopted was because some American had once said it was not used over in America, and therefore nobody had ever thought of applying it over here. Drawing a sketch of the three-wire connections on the blackboard he said that, although in electric lighting on this system the load could be balanced fairly well, in electric traction work this was very much more difficult, and the difficulty in this direction was accentuated because they had to begin on a small scale, and, therefore, might have a lot of cars in one street and none on the other. If they had a block, for instance, all the cars would collect in one street, and there would be very great difficulty in balancing. But surely the booster system was perfectly applicable to the three-wire system of traction work? A comparatively small booster on a three-wire system would do all that was wanted, and the bigger the system the easier it was to manage. On the other system the bigger the installation the worse it was to keep going. He could not help thinking that, especially for very large districts, the three-wire system with a booster on the middle return was very well worth consideration. Otherwise, the only other method of getting rid of electrolysis was to have boosters on the pipes.

Mr. P. V. McMAHON, the engineer to the City and South London Railway, said this line was on the three-wire system, and that balancers with battery sub-stations were used instead of boosters.

Mr. SWINBURNE said Mr. McMahon was speaking of electrolysis where they could control the two sides to some extent. He was speaking of tramways where there was an earthed return and consequent electrolysis of pipes.

Mr. McMAHON thought balancers came very well within the present Board of Trade regulations.

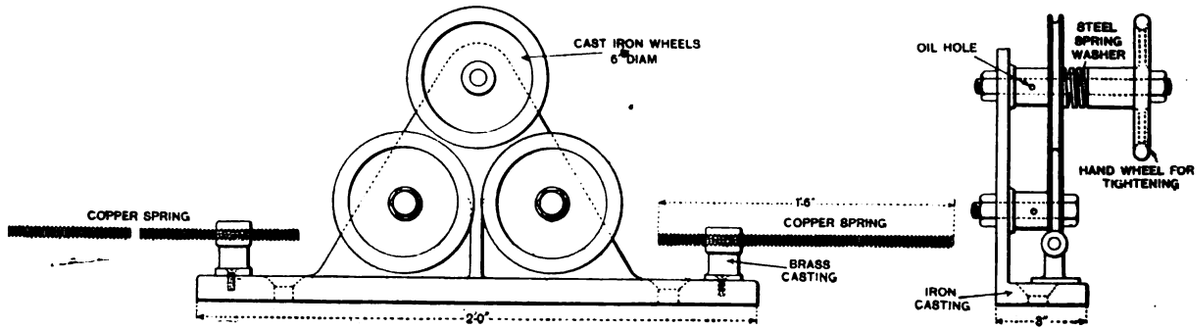
Mr. R. C. QUIN fully agreed generally with all that Mr. Sayers had said, but there were one or two points on which he differed. In the first place he did not agree with the use of drawn-in cables. He had used both systems, and the conclusion he had come to was that if drawn-in cables were used they would soon have to be drawn out again. It was far cheaper to lay cables on the buried or solid system.

Maj.-Gen. C. E. WEBBER remarked that when "Galileo said the earth was round" (*sic*) and his opponents were certain it was flat, Galileo gave his reasons for considering it round and the others did not. This occurred to him when the last speaker said he was quite certain the drawn-up system of cables was bad. He had observed a great deal of tramway construction lately, and it had occurred to him that both as regards the laying of cables and the erection of poles, tramway engineers had something to learn from those who preceded them 20 or 30 years ago in connection with telegraph work. The large quantities of telegraph cables that were fixed in the ground had to be taken up within a very few years, and the drawn-in system was universally adopted. He would, therefore, like to hear Mr. Quin's reasons for objecting to the system.

Mr. H. M. SAYERS, in reply, said he felt happy that his Paper had not met with much contradiction or destructive criticism. Probably Mr. Taylor was right in thinking his estimated cost of attention to motor generators was low. He had not had an opportunity of finding what it actually was in practice, and had not wished to take too high a figure. Mr. Taylor was quite right in saying that the grades and densities of traffic did not affect the limit of distribution; it affected the size of the feeders to different points. With regard to the question of boosters, he pointed out that for brevity he simply took one feeder to the centre of gravity of the district beyond the limiting distance, and it was supposed that all the boosted current was taken there. Mr. Eustace Thomas had given a valuable method of comparing two conductors for a given load, but his own method was more general, and if one took a considerable range of conductors one got a general expression for the most economic density. Mr. Jenkin's remark that his Paper must not be taken as a comparison of different systems was perfectly true. Mr. Jenkin also objected to the suggestion that feeders should be run to separate sections; evidently this had conveyed the idea that each feeder should only feed the trolley wire at one point. But this was not assumed or intended. It was found to be best in practice in a large system, however, to separate the trolley wires at various points and to feed each section of trolley wire with one feeder. On a busy system, if loss occurred through this, many advantages accrued. Mr. Scott wanted to know why he did not estimate for 5,000 volts for the high-pressure multiphase system: but it would make very little difference to the costs. He had worked them out, and in practice he should prefer to work with 2,500. Mr. Scott was quite right, however, as to the great difference in the expense of the system if multi-phase motors were used on the cars, and he had pointed this out himself in the penultimate sentence of his Paper. He agreed with Mr. Swinburne that the three-wire system was worthy of consideration, as there were many cases where it would seem to afford a way out of difficulties now experienced. The difficulty was to find anybody to put the money down for the experiment, because it would be an experiment, as there were many details to be worked out. The difficulty in having two trolley wires was quite imaginary, and, of course, a balancer was what one would use to keep up the voltage on the two sides.

TENSION APPARATUS FOR WIRE WINDING.

Messrs. Mavor and Coulson have recently made a simple apparatus for maintaining the tension on the wire when winding bobbins for electromagnets and similar apparatus, and they inform us that it has been found very useful in their own shops. By the ordinary method of simply winding off a braked drum, there is a risk of the wire being damaged if it fouls or is bent sharply during winding. The present device, shown in the figure, consists of three grooved pulleys, placed triangularly on an iron frame, and two spiral spring guides, the wire passing round the former and through the latter. The upper one of the three pulleys is braked by an adjustable spring washer bearing against its boss, the pressure of this spring being regulated by a hand wheel. The guide tubes consist of spiral springs held in the position shown in the illustration. As the wire passes through the spring, the latter will approximately conform to any bends or slight kinks in the wire and tend to straighten them out; but should it fail to do so, it will merely become compressed as the wire continues to be wound on the bobbin, and the tension on the wire will increase gradually instead of suddenly, giving the operator an opportunity of observing that something is wrong and of stopping the machine before the wire is damaged.



Mavor and Coulson's Tension Apparatus for Wire Winding. Scale: One-eighth.

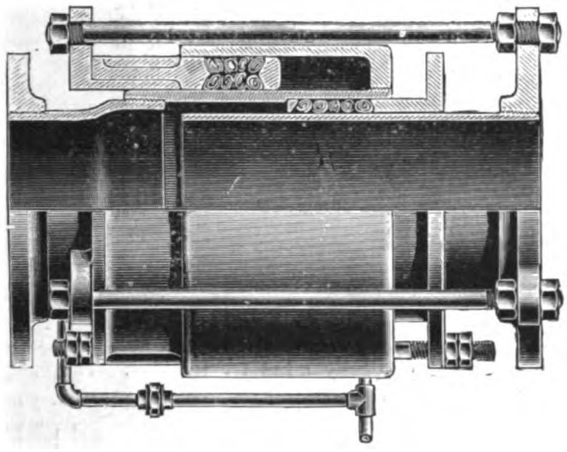
A BALANCED EXPANSION JOINT.

In the balanced expansion joint, shown in the illustration, an annular chamber, provided with a special packing box and piston surrounds the shell in which the sliding pipe works, the areas of the annular piston and sliding pipe being equal. The connections between the pipe and annular chamber are such that the pressure is the same in both, and tends to move the sliding pipe and piston in opposite directions. These forces balance, and the pipe is there-



fore free to slide in or out of the expansion joint without regard to the pressure inside it. The manufacturers of this neat device are Messrs. Brown and Co., 49, Deansgate, Manchester.

IMPERIAL TELEGRAPHIC COMMUNICATION.

In our issue for May 25 we gave a very full abstract of the debate in the House of Commons on May 22, on the motion of Sir E. A. Sassoon, asking that an inquiry should be held "into the commercial and strategical defects of Imperial telegraphic communication." The mover of the motion and the seconder (Sir Charles Dilke) practically dealt with the question from two points of view, the former from the commercial and the latter from the Imperial. Mr. Hanbury, Secretary of the Treasury, in his reply, dealt with more than usual completeness with the whole subject, and on behalf of the Eastern and associated companies a verbatim report of the debate has been circulated, together with the following notes in reply to the various points raised in the course of the debate :—

Winchester House, 50, Old Broad-street,
June 1, 1900.

The debate may be described as the outcome of the various attacks which for some time past have been directed against the British companies owning the submarine cables of the world. In his opening speech Sir Edward Sassoon, like all the subsequent speakers, acknowledged that the British Submarine Cable Companies, by extending British influence throughout the world, had accomplished a great work, as by it Great Britain had been placed in an eminently favourable position. The charges against the companies may be divided into four categories, viz. :—

(*a*) Excessive tariffs.

(*b*) Cables inefficiently maintained.

(*c*) Cables being subsidised by the Imperial and Colonial Governments, the companies do not carry out their contract obligations.

(*d*) Companies hold practical monopolies throughout the British Empire.

1. **TARIFFS.**—In comparing interior with international telegraph tariffs, the fact was apparently lost sight of that the former are fixed by States for messages which have to pass entirely over landlines, or very short cables, and are necessarily fixed at a low figure. These rates have to be arrived at by taking the average distance traversed by each telegram against the average cost of each telegram, whereas the cost of international telegrams has always, more especially when transiting submarine cables, to be based on the transmission over an entire length of line.

Mr. Hanbury referred to Great Britain, and this country may be taken as an example. The average distance traversed by each interior telegram is something like 100 miles, for which one halfpenny per word is paid ; this makes the rate in Great Britain 5d. per 1,000 nautical miles, as compared with the following cable rates of the companies :—

Gibraltar		2·4d.
Malta		2·3d.
Egypt		5·35 l.
India	4s. 0d.	5·96d.
	2s. 6d.	3·72d.
South Africa—Capetown		5·63d.
Ditto Durban		5 32 l.
Australia		3·68d.
New York		3·4d.

It is urged that a rate between India and Europe of 1s. per word should be established, which would equal 1·49d. per 1,000 nautical miles. With regard to such a rate, the following calculation may be of interest.

A new cable between England and India would cost about £1,500,000. The annual cost of this may be estimated as follows :—

Working expenses, including ship	£43,471
Amortisation to replace capital in 30 years	31,529
or	£75,000

without making any allowance for cable used on repairs.

In order to carry traffic expeditiously the cable could only be occupied for, say, 14 hours per day. This would represent, at 7½ paying words per minute, 2,299,500 words per annum, which at 1s. per word, less outpayments, would be equal to £99,000 per annum, giving a profit of £24,000, or 1·6 per cent. on the capital, and it is hardly likely that the public would subscribe money for a company with such a poor prospect.

It is alleged that the tariff between Europe and India has been maintained owing to the astuteness of the Eastern Telegraph Company in arranging, in 1877, a joint-purse agreement with the Indo-European Telegraph Company, and much mystery has been made over this joint-purse agreement.

The facts are very simple. In 1877 the Indo-European Company's line was interrupted for some considerable time owing to the war between Russia and Turkey, and in the interests of their shareholders the directors of that company thought it desirable to enter into a joint-purse arrangement with the Eastern Telegraph Company. The latter company, on its side, was desirous of strengthening its communication with India by having the right to use an alternative route in case of interruption, and a joint-purse agreement was therefore arranged. Six months afterwards the Indo-European Telegraph Department of the Indian Government, who own the line between Teheran and Kurrachee, became a party to the joint-purse, with the object of conserving their revenue.

It was also stated that if the Treasury guaranteed one-third of the loss on a 1s. tariff to India, the utmost that they would be called upon to pay would be £22,000 per annum. The actual facts are as follows :—

The loss on a 1s. tariff between India and Europe, without increase of traffic, would be £270,000 per annum. If the companies took two-thirds of this loss, the Indian Government and the Treasury between them would have to make up £90,000.

Finally, with regard to a general reduction of tariffs, reductions can only conveniently be made during the periodical International Telegraph Conferences, when the representatives of the various interested parties are assembled.

As long ago as August, 1899, the Eastern Company, on its own initiative, informed the British Government that they were quite prepared to negotiate for reductions to and from all British possessions on the basis of standard revenues, combined with a given cable-carrying capacity. The Conference to be held in London next year will, it is to be hoped, provide a favourable opportunity for completing these negotiations. Reductions for South Africa, Australasia, and India have already been agreed to on similar bases.

2. **WORKING.**—Some startling figures were used with reference to the working of the South African cables.

The following, however, are the facts :—Since the cable between Aden and Durban was laid in 1879, it has been interrupted 578 days, or 7·75 per cent. of the total period. Since the laying of the cables in 1839 on the West Coast of Africa, they have been interrupted 663 days, or a total of 17·04 per cent. During the period that two lines have been working with South Africa, simultaneous interruption of the two routes has taken place on 37 days only, or a percentage of 0·92 for the eleven years. Taking the six months ended January this year, the period just prior to the laying of the third cable, the following are the figures :—

East coast cables	50 days	...	or 27·5 per cent.
West coast cables	10 days	...	or 5·43 per cent.
Both cables simultaneously			Nil.

It is customary for the company to keep one repairing ship at Aden, another at Zanzibar, Mozambique, or Delagoa Bay, and a third ship on the West Coast.

Immediately on the outbreak of hostilities, in October last, a ship was sent through the Suez Canal, which took the place of the Aden ship, the Aden ship was sent to Zanzibar, and the ship then at Zanzibar was sent to Delagoa Bay, the ship sent through the Suez Canal being replaced by a ship from London. In this way, ships were at ports within three or four days' steaming distance of any place where an interruption could occur between Aden and Durban, and this operation was carried out in seven days. If the Government had owned the cables, greater precautions could not possibly have been taken to ensure their maintenance.

It must also be remembered that although delays have occurred between South Africa and Europe when single cables have been interrupted, such delay has almost invariably been caused by large Government traffic. In no case have Government telegrams been unduly delayed. The third cable, however, recently opened to the Cape will greatly strengthen the service.

3. **SUBSIDIES.**—It was stated that the Eastern and subsidiary companies had received no less a sum than £3,700,000 for subsidies during the last 20 years. It should, however, be remembered that cable communication was established with the British possessions of Gibraltar, Malta, Aden, Perim, India, China, and Australia, without any subsidy whatever from the Imperial or Colonial Governments. This fact was emphasised by Mr. Hanbury, but is almost always ignored by the companies' critics.

The first substantial subsidy arranged was paid by the Australian Colonies for a *duplicate* cable between Australia and Penang. This line was not required for increased traffic, but was laid in order more effectually to maintain a continuous service. At the time this duplication was arranged, the whole value of the Australasian traffic to the Eastern

Digitized by Google

Extension Company was only £84,000. The estimated annual cost of the duplication was £64,500, towards which the Australian Colonies agreed to give a subsidy of £32,400 per annum for 20 years, the company itself taking the remaining liability.

Since the laying of the second cable, telegraphic communication with Australasia has only been totally interrupted 41 days in 20 years, or 0·56 per cent. of the period. In 1889 the company, without any extra subsidy, laid a third cable, connecting Western Australia, at a capital cost of £120,000.

It should also be remembered that for the above subsidy the Australian Governments were granted half rates for their official messages over the Eastern Extension Company's lines, and this privilege was also granted to the Imperial Government, although they did not contribute anything towards the subsidy.

The next subsidy granted to one of the associated companies was for connecting Aden with South Africa. This was for £55,000 per annum, made up by contributions from the Imperial Government of £35,000, Cape Colony £15,000, and Natal £5,000. But there is no doubt whatever that in 1879, when this line was opened, no cable company could have been induced to lay a cable to South Africa without substantial Government assistance. The cable, being urgently needed, was laid very expeditiously owing to the Eastern Extension Company allowing their already manufactured Australian duplicate cable to be used for the purpose. For the first five years the annual revenue from the cable only averaged £85,000, whereas the cost of working, including interest and sinking fund on debentures, was £57,000, leaving £28,000 for interest on capital, without any allowance for reserve.

The South African subsidies have amounted, during the 20 years that they have been paid, to £1,100,000, and it should be borne in mind that the company, without any additional subsidy, arranged a duplicate line to South Africa by the West Coast.

Another subsidy has been paid by the Imperial Government for communication with Seychelles and Mauritius, of £28,000 per annum, and it is quite certain that the Imperial Government would not have agreed to pay this subsidy to the Eastern Companies if they could have obtained the cable on more favourable terms elsewhere. Had the cables between Zanzibar, Seychelles, and Mauritius been subjected to many interruptions the amount of revenue earned, including the subsidy, would have been entirely inadequate.

The African Direct Company also receives a subsidy from Great Britain for connecting the West Coast of Africa, and when it is considered that the English Government has six British stations connected for £19,000 a year, whilst the Portuguese Government are guaranteeing £41,000 per annum for five stations, it cannot be said that for a strategic line of this character the taxpayer of Great Britain has anything to complain of.

No subsidies have been granted by the British Government without conditions limiting the time for repairs, maximum tariffs, and giving the British Government half rates for their official telegrams.

4. **MONOPOLIES.**—As stated by Mr. Hanbury, the Eastern Associated Cable Companies have no absolute monopoly in any British possession. They have a preferential right in Egypt, and preferential rights in connection with the Hong Kong-Labuan-Singapore cable, but these privileges may be terminated at any time by the purchase of certain cables. The Eastern Company has monopolies in some foreign countries, but surely this is to the benefit of British commercial enterprise.

For the 30 years during which the cables of the associated companies have been gradually extended to every part of the world, not a single cable has been laid to any British possession in opposition, although, as has been pointed out, no monopoly of landing rights is held by the companies. It is therefore difficult to understand why, because the business has been carried on successfully with British capital, and because no other association has thought it worth their while to compete on commercial grounds, the Imperial Government should now be called upon to compete by laying cables of their own, guaranteed by the taxpayers' money, against cables that have been laid purely from a commercial point of view, without subsidies and without monopolies. But even if this happened the companies would not claim compensation provided that fair tariffs were established, and they were accorded equal rights and facilities for dealing with their traffic as might be enjoyed by Government or other competing cables ; they would certainly claim compensation if Government cables were laid and worked at a loss and taxpayers' money used to make up deficiencies.

Some supporters of the proposed Government Pacific cable maintain that all traffic intended for the existing companies' cables should be controlled by the Governments interested in that cable, and that the companies ought not to be allowed to deal with their own traffic in Australia in a similar manner to that prevailing in Great Britain and Canada, otherwise the Pacific cable would become a financial failure. This objection, however, is scarcely consistent with the ostensible objects of the Pacific scheme—namely, the breaking up of the companies' so called monopoly, and the cheapening of the tariffs to Australia.

The statement that the British Government is losing about £90,000 per annum, owing to having surrendered its terminal rate, is not correct. The British Post Office, under the Telegraph Act of 1868, allow the cable companies to deal direct with the public in Great Britain, and for this purpose the companies pay to the Post Office a rental for the landlines from their cable landing stations to the very large centres of trade in the country. They also bear the cost of collection and delivery of telegrams at these centres, and on telegrams dealt with by the Post Office, pay the ordinary inland tariff ; consequently they naturally retain the British terminal rate which is inscribed in the International Tables as belonging to Great Britain.

As far as the companies are concerned, they are quite willing, *if their customers desire it, and all private companies are treated in the same manner*, that the Post Office should undertake all the collection and delivery in this country.

A graceful reference was made during the debate to the companies concessions during the present war. They may be briefly summarised as follows :—

1st. All inquiries, and the replies, with regard to wounded officers and men serving in South Africa, are sent *free*, provided they are certified by the War Office.

2nd. Any social telegrams desired to be sent between the officers and men serving in South Africa and their friends in Great Britain or the British Colonies, are transmitted as Government telegrams at Government rates, these telegrams being collected and delivered by the Government authorities.

3rd. Telegrams relating to the various funds which have been started in Great Britain and elsewhere are also transmitted *free*.

With regard to strategic cables, it may be pointed out that in the companies' opinion, cables could be cut in deep water practically as easily as in shallow water, and that the safest position for submarine cables is to lay them along trade routes where men-of-war would have to be stationed in time of disturbance, and that communication should be opened with every place by as many different routes as possible.

As to the suggested purchase of the submarine cables, it may be remarked that cables in moderate depths can now be repaired with comparative ease, and long lengths of new cable are from time to time inserted where required, so that a large proportion of the companies' lines are now in practically as good a condition as when they were originally laid.

A great point was made by all the speakers of the fact that immediately competition viâ the Pacific was definitely agreed upon by the British Government the companies proposed to lay the Australia-Cape-Great Britain cables without subsidy, and at the same time reduce the tariff, although they had previously asked for subsidies. The facts are as follows :—

A subsidy of £20,000 per annum for 20 years was asked for for an all-British cable between South Africa and Great Britain, and this condition has never been withdrawn, but the company was quite willing to lay a commercial line viâ St. Vincent without subsidy, and this has been done, and the Government has acknowledged the justice of a subsidy for an all-British cable by agreeing to give £4,500 per annum for 20 years for a portion of the all-British cable to be laid between Sierra Leone and Ascension.

For the cable between South Africa and Australia a subsidy of £5,000 per annum was required for connecting the British islands of Rodriguez and Cocos, together with a continuation of the Australian duplicate subsidy of £32,400 for 10 years, this latter being equal to £18,577 for 20 years.

This proposal was made more than three years ago, but owing to the large increase of Australian business, almost entirely due to gold speculation in Western Australia, the companies now find themselves in a much stronger financial position than was anticipated, and are, therefore, able to undertake the large expenditure of £1,750,000 unaided by Government, which they were not in a position to do at the time the original offer was made.

CORRESPONDENCE.

LONG DISTANCE TRANSMISSION OF POWER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The President of the Institution of Electrical Engineers has taken the trouble to write two letters in one number of your journal in support of statements which he made when discussing a Paper by an ordinary member, read at the Institution. If these criticisms be erroneous, and if the member dislikes to take part in a controversy of a personal character, yet even then the rules of courtesy demand that he should take some notice of the honour bestowed on his work by the criticisms of one occupying so prominent a position.

With these preliminary observations I will, with your permission, make a few impersonal remarks regarding a Paper on electric power transmission lately read by me before the Institution of Electrical Engineers.

1. If anyone imagines that he cannot get a worse efficiency than 50 per cent. in a transmission line, let him try it (it is easily tried in the laboratory), and he will find that he can get any efficiency between 0 and 100 per cent.

If he prefers to think it out, and gets puzzled by not noticing that the speed of the motor at the receiving end can be reduced to any amount by increasing the mechanical resistance, let him consider the case where incandescent lamps are used instead of a motor. Let him use 400-volt lamps, and so many in parallel as to give 200 amperes. Then, if the generator delivers 1,000 volts to the line, and if the line has 3 ohms resistance, he will have no difficulty in realising that the efficiency of transmission is only 40 per cent. *In no sense* is it true that the efficiency cannot be less than 50 per cent.

2. On looking at Table II. of my Paper referred to above, and using 0·12 efficiency, it will be seen that 8·27 H.P. must

Digitized by Google

be generated for every horse-power delivered at the end of a booster line of two sections, and 2·88 H.P. must be delivered at the end of the first section. It will also be seen in the table that the copper in the two sections together is 0·504 tons, and it is 0·374 tons for the first section, at the end of which section 2·88 H.P. is delivered with an efficiency 0·8464.

Now, if anyone, when attempting to prove my tables wrong, should be so careless as not to notice these facts, and if in consequence he were to assume that the weight of copper in the first section was only half of that in the two sections, and that only 1 H.P. instead of 2·88 H.P. was delivered at the end of that first section, he would inevitably be led to the erroneous conclusion that, "with the very same conductor and same generator voltage" he could "deliver the same power with an efficiency of 0·6536 or more" (in fact, 0·67), "through that section." But the tables given in my Paper would be none the worse for his criticisms.

3. The advantages of the booster method become most important only in special cases of unlimited cheap power, long distance, and no excessive voltage. I have no desire that everyone shall adopt the methods that I adopt for planning transmission schemes; and I do not propose at present to explain any further the methods which I adopt in special cases in practice.

I have to-day departed from my rule of refusing to take notice of imperfectly-considered criticisms. I have done so only in deference to the prominence of the position held by Prof. Perry. But whilst I shall decline in future as I have done in the past to waste my time and your space in useless personal controversy, I shall at all times be pleased to acknowledge in your journal any real error in my work that your correspondents may point out. The tables published in my Paper before the Institution of Electrical Engineers have been checked by four computers, and you may rest assured that they are correct.—

Yours, &c., GEORGE FORBES.

Westminster, June 5, 1900.

ELECTRIC BOATS FOR THE THAMES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Your note in the current issue puts many points in favour of an electric passenger service in a definite manner, and should help to gain financial support for such a scheme. I would like to supplement what you say by a few actual figures based on results obtained with the Callow-Eck system of electric launches.

For a service on the Thames between Greenwich and Battersea, at five-minute intervals, in large and safe boats, the cost per passenger mile, including all charges (*i.e.*, rents, salaries, depreciation, and maintenance, as well as generating and navigating expenses), allowing for the boats to be on the average only one-fifth full, would be 0·16d., so that for a penny fare either way from London Bridge passengers could be carried at a profit provided there were no pier dues. Taken that the boats were only one-fifth full on the average, such a service would produce over 10 per cent. on its capital, or if this were divided into a secured debenture and ordinary shares the latter would receive over 15 per cent. The problem is, therefore, quite in the region of practical economics, and will, I trust, be put into working long before the London County Council get powers to establish a river service.—

Yours, &c., JUSTUS ECK, M.A., M.I.E.E.

London, S.W., June 6.

LEGAL INTELLIGENCE.

Crow (District Surveyor) v. Whitechapel District Board of Works.

At Thames (London) Police Court last week, the magistrate, Mr. Dickinson, delivered judgment in a summons by Mr. Arthur Crow, district surveyor, against the Whitechapel Board of Works for executing certain work in Great Prescott-street, without serving a building notice, in accordance with the London Building Act. It appeared that the board have been engaged laying electric lighting cables and inspection chambers under the footway. The chambers were brick built, with iron joists for the roof, and no notice had been given of these works. The chambers were provided to facilitate handling the cables in case of necessity without disturbing the paving.

Mr. DICKINSON said it was a summons taken out by the district surveyor against the Board of Works, for not having given him (the district surveyor) notice before certain works, viz., the construction of boxes or chambers under the street for the purposes of electric lighting were begun. For the defence, it was contended that it was not necessary to give such notice, first, because the London Building Act, 1894, did not apply, the boxes being constructed under the provisions of the Electric Lighting Orders Confirmation Act, 1892, a special Act which was not consistent with the general Act, and therefore overrode it; and, secondly, because even if the general Act did govern it, those boxes were not "buildings, structures, or works" within its meaning. By sec. 72 of the London Building Act, 1894, it was enacted that any construction under any public way should be constructed in such manner as might be approved by the district surveyor; and by sec. 145 where any "building, or structure, or work," was about to be begun, a building notice respecting it must be served on the district surveyor. In the 1892 Act the clauses relied on by the defence were clauses 11 and 12. Clause 11 gave power to undertakers (*i.e.*, the Whitechapel Board of Works) to "construct" boxes in the streets. The third paragraph of that clause enacted that every such box should be constructed in such manner as not to be a source of danger by reason of inequality of surface (*i.e.*, to the public using the street), or otherwise. Who was to be the judge whether there was any such danger? Probably not the undertakers themselves, but the duly appointed officer under the Building Act, whose duties were imposed by sec. 72 of that Act. Clause 12 required a notice of the works, with plan, to be served on the Postmaster-General and also upon the London County Council: on the Postmaster-General on account of the exigencies of the Post Office, and on the London County Council because if the street was repairable by them the other provisions of the section should, with the necessary modifications, apply to them in like manner as to the Postmaster-General. It appeared to him (the learned magistrate) that the 12th clause only dealt with the notices to be given to the Postmaster-General and the County Council for the purposes he had mentioned, and had nothing to do with the notice required to be given to the district surveyor where any structure was to be made under any public way, that he might look after and guard the safety of the public using the way. It was asked, "Why give notice to the district surveyor?" who "had nothing to do with the streets." The answer to that was the 72nd section of the Act. The principle which had to guide him in coming to a decision on that point was, Is there anything in the special Act of 1892 so inconsistent with the general Act of 1894 that they cannot stand together? If such inconsistency did exist the provisions of the special Act must override those of the general Act, and it had been held in the "City and South London Railway Co. *v.* London County Council," and "London County Council *v.* School Board for London," that such inconsistency did exist. But if the provisions of the two Acts were reconciliable, the cases of "Uckfield Rural Council *v.* Crowborough District Water Co.," and more recently the "London County Council *v.* the Wandsworth and Putney Gas Co." decided on April 2, 1900, show that the provisions of the general Act must prevail. He was unable to see any inconsistency there. The undertakers, who were by statute given powers for interfering with the streets, had to give notices (for certain purposes) to the Postmaster-General and to the County Council, but that liability was quite consistent with an obligation to give notice to the district surveyor (as they would have had to do had they been doing any similar work not under any statutory powers) in order that he might see that the work was properly done for the public safety. Further, upon the question of whether the Building Act applied, it was important to look at sec. 201, the exemption clause, which did not include electric lighting, though it specially mentioned railway, dock, and gas companies; but there was a section (203) which did specially mention electric supply companies, and exempted certain buildings (those boxes or chambers not being amongst the number) from the general provisions of certain parts of the Act, the inference to be drawn therefrom being that the other buildings of such companies were to be subject to the provisions of the Act. Upon the second point, whether those boxes or chambers, which were admittedly of varying size, were "buildings or structures or works" within the meaning of the 145th section, he was of opinion that they were. They were the artificial work of man, excavated, and then specially constructed with bricks and mortar, and used for a definite purpose. He could see no reason why the terms should not apply to buildings below as well as on the surface of the ground, which, indeed, was the view expressed by the judges in "Thompson *v.* Sunderland Gas Co." He found that in the case of "The Mayor and Corporation of Tunbridge Wells *v.* Baird," Lord Halsbury, Lord Herschell, and Lord M'Naughton spoke of a convenience which the Corporation had made in one of the streets, sunk to a depth of 9ft., and lighted by skylights on a level with the surface of the street, as "a building, the erection of which is complained of," "construction of this underground chamber," &c. As a matter of fact and of law, then, he found that those boxes or chambers came within the 145th section. He, therefore, imposed a nominal penalty of 1s., and £10. 10s. costs, and agreed to state a case.

Sanding Tramway Tracks.—An appeal was heard on Tuesday and Wednesday, in the Queen's Bench Division, Dublin, from the finding of Mr. Swifte, divisional police magistrate, in December last (see *The Electrician*, Vol. LXIV., pp. 89, 200 and 271), as to the party liable for the sanding of tramway tracks in the case where an electric line is in operation. It will be seen that Mr. Swifte's decision involved the Dublin United Tramways Co. in this liability. The appeal was brought to set aside this decision. After the hearing of arguments the Court, consisting of the Lord Chief Baron, Mr. Justice Andrews, Mr. Justice Madden, and Mr. Justice Boyd, reserved judgment.

Digitized by Google

GLASGOW TRAMWAY TENDERS.

(By Telegraph.)

[FROM OUR OWN CORRESPONDENT.]

GLASGOW, *Thursday, June 7.*

At a meeting of the Glasgow Town Council to-day (Thursday) the Tramway committee recommended that as the electric car equipments did not comply with the specifications, the offer of Messrs. Dick, Kerr & Co. for additional car equipments be cancelled, and that additional car equipments be advertised for.

Mr. PATON moved the approval of the minute and Mr. OATTS seconded.

Bailie KING moved that the minute be taken back for re-consideration. He narrated the negotiations with Messrs. Dick, Kerr & Co. and the Westinghouse Co. in regard to their respective offers for car equipments, and alleged that a preference had been shown by Mr. Young, the manager, for the Westinghouse Co. If it was desired to give this order to the Westinghouse Co. let it be done openly. He was satisfied that great damage was being done by the action of the Corporation in this matter. He had noticed in American and other papers that on this subject the Glasgow Corporation tramways department was quoted as against Glasgow manufacturers. He did not know that their experience of American work was such as to cause them to show this preference. The American engines at Springburn were causing great anxiety to the men working them. He might also remind the Council that the American firms received a former order because they were the lowest, and now they were to receive another order because they were the highest, so that there was evidently a desire to give a preference to the American firm. In fact, he believed the real complaint against Dick, Kerr and Co. was that they had rubbed Mr. Young the wrong way.

Bailie W. F. ANDERSON said after the remarks of Bailie King he wished a categorical answer to two questions: Were the Westinghouse Co. permitted to amend their offer after the contracts were opened? Did the Westinghouse Co. get an order for so many car equipments, and, did the Council pass an order for one kind of car equipments to Dick, Kerr and Co.?

The DEPUTY-CLERK (Mr. Monro) read the minute of the Tramway committee of Feb. 20, which stated that car equipments were ordered from three firms, one order being for 100 car equipments from Dick, Kerr and Co.

Mr. PATON said he thought the matter had been settled, because it had received a great deal of consideration in committee, and they came to a conclusion in which everybody was satisfied, with the exception of Bailie King. The motor was probably, with the exception of the engines, about the most important thing in connection with the working of the cars. There was no question in this matter of America versus England, because he believed that both the companies concerned had shareholders in England. In connection with the Springburn route they got motors from the British Westinghouse Co., and these were tested by Mr. Young and found thoroughly satisfactory, and they were working on the Springburn route at the present moment. Motors were also got from Dick, Kerr and Co., and were reported to be unsatisfactory. In the present case a large order for motors had to be placed, and the question came to be where they were to get the best motors for the work. They got offers from the Westinghouse Co. and from Dick, Kerr and Co. Mr. Young reported that there was no difficulty in accepting the Westinghouse Co.'s motors, simply because they had tried and tested them in every way and found them to be satisfactory. He hoped no one would be led away by Bailie King's talk about prejudice on the part of their officers. He acted simply on public grounds, and his desire was to do the best in the public interest, and he could say that as definitely for Mr. Young. Mr. Paton then read a long report by Mr. Young dealing with the respective motors of the Westinghouse Co. and Dick, Kerr and Co., and proceeded to say that it was not until Bailie King came into the field, and gossip got about outside of the committee through Bailie King, that Dick, Kerr and Co. declined to proceed with an arrangement which they had previously agreed to.

The LORD PROVOST said Mr. Paton was not in order in attributing motives to a colleague.

Mr. PATON said he believed he had stated the facts. He had the authority of Mr. Young for saying that the representative of Dick, Kerr and Co. agreed to supply six motors. It was about this time that Bailie King began to take a great interest in the matter, and very shortly afterwards Dick, Kerr and Co. withdrew the offer to supply these six motors. The committee next got Dick, Kerr and Co. to supply them with drawings, and after a good deal of trouble they got these drawings, and had a report from their three engineers agreeing that the drawings submitted would not do the kind of work they were required to do, and, he asked, was it fair and reasonable to accept offers for motors that would place them in a position that might mean disaster. He hoped the Council would do nothing of the kind; that they would depart from the contract for these 100 motors, and re-advertise, when Messrs. Dick, Kerr and Co. might have an opportunity of again offering.

Bailie W. F. ANDERSON asked if it was the case that the Westinghouse Co. were allowed to amend their offer.

Mr. PATON said it was not the case.

Bailie KING said it was not the case that Messrs. Dick, Kerr and Co. offered to supply six motors.

Mr. PATON: I have given you my authority.

Bailie D. M. STEVENSON asked Bailie King to withdraw his amendment. He had fought very well for Messrs. Dick, Kerr and Co. and he should withdraw.

Bailie King then withdrew his amendment.

Another question of contract arose on the minute of the Tramway committee recommending that the offer of Messrs. John Green and Co. for the brickwork of the Pinkston power station should be accepted. The price was £56,835. 12s. 2d.

Mr. PATON moved the approval of the minute.

Mr. WILSON BUCHANAN took exception to this minute. This offer had been accepted irregularly. The offers for this work should have been received by 5 o'clock on May 21. They were opened at 11 o'clock on May 22, and three hours later—or 21 hours after the time specified—this offer was received.

Mr. PATON said that Mr. Buchanan agreed in committee to allow the decision to be unanimous, and he appealed to him in the public interest not to raise the question.

Mr. BUCHANAN declined. They received tenders, the lowest of which was £61,000; yet this tender, which came in 21 hours late, was accepted. It was not in the public interest that this method of doing business should be followed by the Corporation.

Treasurer MURRAY asked if it was competent for Mr. Buchanan, who was present at this meeting, to raise this question if the minute was correct.

The LORD PROVOST said Mr. Buchanan was challenging the accuracy of the minute.

Mr. FORSYTH asked if it was true that this contract was accepted 21 hours after the time specified.

Mr. PATON said it was opened about two or three hours after the other offers.

Mr. STEWART moved that the matter be remitted back. Mr. MAXWELL, in seconding, said a gross irregularity had been committed. They had a number of honourable contractors, and if it got abroad amongst them that such actions were possible in the Corporation they could hardly expect the respect they ought to have.

Treasurer MURRAY admitted an irregularity had taken place, but as a protest he would vote for the minutes.

Mr. HUGH ALEXANDER said as a member of the committee he was not ashamed of the action of the committee. He admitted the tenders were to be in at 5 o'clock on the Tuesday, but on the Wednesday there had been a continuous meeting of the Tramway committee for more than two hours and not a single member objected to the opening of the contract. He contended the committee were justified in opening and accepting the offer.

Mr. PATON admitted an irregularity had been committed. The committee had been sitting continuously from 11 o'clock till 2 o'clock, and when this tender came before them, about 2 o'clock, the committee agreed to its being opened. It was from a first-class man, and it was found to be £4,165 less than the next offer. Had it been a matter connected with their own private business not one of them would have considered it dishonourable to accept it. He could, however, assure the Council that the committee would in future be more careful.

Mr. Stewart withdrew his amendment, and the minutes were then agreed to.

MUNICIPAL, FOREIGN & GENERAL NOTES.

Blackburn.—The first annual report of the Blackburn tramways since their municipalisation shows a net loss of £4,500. Upon one-half of the line electric traction has been substituted for steam. The deficiency is mainly due to the reduction in fares, increase in wages, and the increased cost of coal.

Bootle.—The electric tramway service on the Stanley-road route commenced running on the 27th ult. There is an outstanding dispute between the Corporations of Bootle and Liverpool in regard to the tramways now before the Board of Trade.

Buenos Ayres.—It is announced that the City Council, who some time back granted a concession for the working of an electric tramway down the extensive Calle Cordoba—which line is already working—has lately given permission to a company using horse traction to run their cars over the electric lines. The mayor has, however, vetoed this latter permission, and a project is before the Buenos Ayres Congress to abolish the City Council, whose action in connection with electrical enterprises has proved mischievous and retrograde.

Clevedon.—The Council are about to advertise for tenders for public lighting for one, two, or three years.

Colchester.—The Corporation have resolved to apply for a tramway provisional order. A scheme for wiring premises on the easy payment system has been prepared by the Electric Light committee. The chairman (Councillor Barritt) stated that intending consumers are to have the services of the borough electrical engineer, who will inspect the premises and prepare specifications for wiring and fitting. Tenders are then to be obtained from local tradesmen and submitted to the consumer. The work will be executed under the supervision of the electrical engineer, and a small charge of £1 on the first £10 outlay, and 10s. for every £10 or fraction of £10 afterwards will be made. The consumer will pay 10 per cent. of the total cost on completion of the installation, and the balance by 20 equal quarterly payments. The Electric Light committee anticipate a large demand for current during the coming winter.

Cradley Heath.—The electric tramway now being constructed by the British Electric Traction Co. connecting Cradley Heath, Old Hill and Dudley, will be opened for traffic about the middle of July.

Digitized by Google

Dewsbury.—The Corporation has notified the Yorkshire Electric Power Co. that they will not be prepared to take supply of electricity in bulk under the company's power scheme for the manufacturing portion of the West Riding.

Dudley.—The Tramway and Electric Lighting Committee recommend the free wiring of all consumers' premises and the borrowing of £10,000 for this purpose. Further, that customers be charged 6d. per unit for the first two hours and 1½d. afterwards, or 5d. per unit throughout, at their option. Meter rents to be abolished. It is proposed to light the Town Hall buildings electrically and to purchase from the British Westinghouse Co., for £1,360, the engine and dynamos at present hired by the Corporation.

Durham.—The British Electric Traction Co. have notified the City Council of their intention to apply for powers to construct electric tramways in the district.

Ealing.—Sanction is being sought for a loan of £10,000 for electric lighting extensions. The District Council has resolved that all applicants for a supply of electric current beyond 60ft. from the mains shall be called upon to pay the cost of connections at the rate of 6 per cent. per annum upon the additional outlay involved.

Edinburgh.—An unsuccessful attempt was made by treasurer Cranston, on Tuesday, to induce the Corporation to rescind the resolution passed at the previous meeting fixing the charge for electric current for next year at 3½d. per unit.

Electrical Enterprise in Italy.—The city of Genoa is now well supplied with electric tramways. During 1899, 6,417 metres of line were laid, bringing the total up to 49,383 metres, over which 61 cars run daily. There are, in addition, the funicular railways, these lines together carrying in 1899 over 14,500,000 passengers. Electric lines are now open from Genoa to Nervi and on to Pegli. An extensive range of customs and bonded warehouses is being erected at Genoa by an Anglo-Italian joint-stock company, the first block of buildings being estimated to cost £225,000. Seven electric lifts have already been supplied by a Milan firm, and the electric light and power generating plant and nine electric cranes by Messrs. Siemens and Halske, of Berlin.

At the great ironworks and shipbuilding yards of Messrs. G. Ansaldo and Co., of Cornigliano and Sestri Ponente, some of the largest tools in the world have been erected, and are mainly driven by electric power. At this company's steel works, also at Cornigliano, plant is being put down for the construction of electric machinery, apparatus and accessories of every kind, and a large electricity generating station has been equipped to provide power for lighting and driving the company's extensive works and yards in this district. This firm is one of the most enterprising in Italy.

At Spezzia, public and private lighting was inaugurated in September last, and is making good progress.

Fenton (Staffs.).—The cost of erecting and equipping electricity works by the Council is considered to be too great to justify the establishment of an undertaking of this character for the present. The Council obtained its provisional order in 1899.

Freiburg (Baden).—This town is to be electrically lighted. Messrs. Siemens and Halske, of Berlin, have secured the contract for the erection and equipment of electricity works.

Glasgow.—The gross receipts of the Corporation tramways department during the year ended May 31 amounted to £464,763. 13s. 4d., compared with £433,128. 0s. 6d. in the preceding year, an increase of £31,635. 12s. 10d.

Grimsby.—The electricity works in this town are approaching completion. It has been decided to fix the charge for current at 5d. per unit for private consumers. Prof. A. B. W. Kennedy has been asked to prepare specifications for the additional plant required to supply the demand of the local tramways company, who are taking current from the Corporation mains.

Halifax.—In the statement submitted by the Finance committee at the Council meeting on Wednesday, the profit on the working of the electricity department for the past year was put at £5,489, and on the tramways £3,117.

Hampstead (London).—For some time past there has been friction between the Vestry and Messrs. W. T. Glover and Co. on the question of liability for making good certain cables which were laid about five years ago, and which have proved defective. A satisfactory arrangement has been come to between the parties, and a recommendation made by the Lighting committee that an offer from Messrs. Glover and Co. should be accepted has been approved.

Hereford.—The report of the Electric Lighting committee just issued states that the net loss for the past quarter on the electricity undertaking was £36. The demand for current is growing at so satisfactory a rate that further plant will be required to meet next winter's load. The gas undertaking has in no way suffered by the competition of the electricity department.

Howth and Sutton (Dublin).—The clerk of works of the North Dublin Rural Council (Mr. Morris) has been instructed to submit estimates for lighting the district by electricity, gas, or oil.

Hunstanton.—The Council will apply for a provisional order, and a special meeting is to be held in August for passing a formal resolution.

Lecture.—Prof. O. J. Lodge delivered a lecture on "Electrical Vibrations" on Saturday last, at University College, Liverpool. The lecture was illustrated by a number of interesting experiments.

Leeds.—The York-road section of the electric tramway was opened on Wednesday.

Leith.—A report on the proposed extension of the electric light mains to Newhaven and Trinity has been prepared by the late burgh electrical engineer (Mr. W. A. Bryson). It is estimated that the income from public lighting and 40 private consumers in the district would amount to £700 per annum. The sinking fund and interest on the capital expenditure (£10,687. 4s. 3d.) would be £748. An alternative shorter route for the mains is set out, involving a present expenditure of £5,495 and an estimated revenue of £400. Mr. Bryson concludes his report as follows: "As there seems to be a feeling in the minds of several members of the Electric Light committee that I have deceived or misled them regarding the capacity of the cables throughout the burgh, I would respectfully point out that my instructions were to lay down an installation, including engines, boilers, dynamos, mains, &c., for 12,000 8 c.p. lamps, which is practically the scheme accepted by you in Prof. A. B. W. Kennedy's report. I think it must be patent on reflection that it is rather too much to expect that the feeders designed for 12,000 8 c.p. lamps can carry 20,000 8 c.p. lamps, which is our present satisfactory condition."

Bailie Manclark reported on Tuesday that the number of customers of the electricity department had increased from 76 in May, 1899, to 210, with a total equivalent of 18,088 8 c.p. lamps. The income for the 10½ months of last year amounted to £3,370, and the working costs to £2,348, showing a gross profit of £1,071. Interest and sinking fund amounted to £1,721, which left a net deficit of £649, to cover which £1,000 was borrowed from the Burgh General Assessments, and of this £350 had been carried forward. Included in the £1,721 was a sum of £604, repaid to the Public Works Loan Board. Adding this to the £350 they had a total of £954, and taking this from the £1,000 borrowed from the General Assessments they had a deficit of £45 for the first 10 months' running. The statement showed that they were on the right lines, and he thought that before twelve months were up they would have a surplus on hand.

Light Railways.—The Light Railway Commissioners held an inquiry at Mansfield, last week, into the application of the Mansfield and District Light Railway Syndicate for power to construct an electric tramway between Sutton-in-Ashfield, Mansfield, and Mansfield Woodhouse. It was stated that the promoters had agreed not to use or take electricity for use on the line except from the mains of the Mansfield Corporation supposing that Corporation were able and willing to give such supply, and in the event of the Councils of Sutton and Mansfield Woodhouse having powers to generate and supply electric current, the current required for working the tramways in these parishes should be supplied by the respective Councils. The syndicate further undertake to attach overhead wires to buildings along the route of their line should the Mansfield Corporation so require. The Corporation has power to purchase such of the tramways as lies within the borough of Mansfield after 30 years, and in the event of the Sutton and Mansfield Woodhouse Councils not desiring to purchase the syndicate will retain powers to run over the Mansfield lines in the event of the Corporation exercising their option of purchase, the purchase price to be 10 per cent. on the capital outlay. The total cost of the line was estimated at £77,533. Mr. C. H. Gadsby gave evidence that the curves and gradients on the line were easy, and no engineering difficulties were likely to be met with. The trolley system could, he said, be successfully applied in the Mansfield district. Mr. J. H. White, deputy town clerk of Mansfield, said the Council had obtained a provisional order, and intended to construct electricity works in Mansfield as soon as they knew the grant that would be required. Other representatives of the local authorities gave evidence in support of the scheme. The Earl of Jersey, who presided at the inquiry, notified that the Commissioners would recommend the Board of Trade to grant the application subject to a slight amendment in the clauses.

The Glossop Town Council have been asked to favour a scheme for the construction of a light electric railway between Glossop, Hyde and Stalybridge.

The Crewe Town Council have decided to apply for an order to construct a light (electric) railway in Crewe and district. The Cheshire County Council and the Nantwich Rural Council have been asked to sanction the scheme.

Ald. A. Thomas has resigned his position on the Swansea Electric and Tramways committee in order to oppose the Corporation light railway scheme at the forthcoming inquiry.

Malton.—In the electric lighting provisional order for the Malton district the promoters had provided for the erection of generating works outside the district, and the opposition of the District Council to the order was caused by this proviso. The promoters have agreed to erect the works within the district and the opposition of the Council has now been withdrawn.

Digitized by Google

Manchester.—As the outcome of the debate at the Corporation meeting last week on the position of the electricity department, the Electricity committee have appointed a sub-committee, consisting of Ald. Doyle and Councillors Batty, Bowes, Boyle, Dr. Bishop, Lambert and Phythian, to inquire into and report upon the entire administration of the department.

Manila.—It is reported that the electric lighting of this town, which is conducted by a Spanish joint stock undertaking, is carried out on first-class lines. Considerable extensions to the plant are now being put down, and Manila will shortly be one of the best lighted towns in the East. The telephone service is also in Spanish hands, and is, it is stated, admirably conducted. According to all reports splendid opportunities for the employment of capital and talent offers at Manilla and other parts of the Philippines.

Monte Video.—We dealt recently with the proposals before the local authorities in Monte Video for the conversion of the horse tramways into electric lines. The *Monte Video Times* states that these negotiations have fallen through.

Middleton.—The Corporation and the British Electric Traction Co. have come to terms as to the supply of electric energy by the Corporation for driving the company's tramways now being laid between Chadderton and Manchester, viâ Middleton.

Municipal Corporations' Associations.—An important gathering of the Association of Municipal Corporations was held in the Royal University Buildings, Dublin, on Saturday last, at which a very large number of English and Scotch municipal representatives were present, including the Lord Mayors of Dublin, York, Manchester, Belfast and Cork; Sir J. Savory, M.P., ex-Lord Mayor of London; and the Mayors of many of the principal towns in the kingdom. After the Lord Mayor of Dublin had introduced the proceedings Sir Albert Rollit, M.P., President of the Association, took the chair. He gave a general review of the proceedings before Parliament, which chiefly affected municipal bodies, after which a series of resolutions were submitted. The first dealt with the expediency of shortening the procedure and curtailing expense in connection with the promotion of municipal private bill legislation in Parliament, and this resolution was unanimously adopted. The Town Clerk of Huddersfield moved the following resolution in connection with municipal tramway enterprise:—

That in the opinion of this Association it is expedient that the Tramways Act, 1870, be amended so as to empower the Board of Trade, on the application of local authorities, to settle and make provisional orders for the construction and working of tramways beyond the districts of such authorities, provided that such tramways will form a connection with any tramways of such local authorities within or beyond their districts.

The President, speaking to this resolution, said the present House of Commons was by no means a favourable one to the rights of municipalities, who were not going to have their rights, whether in reference to electric light, electric power, tramways, or telephones, restricted simply and solely within the limits of their boundaries. If the community were in favour of the extension of the limits, who were so well able to determine what was for the interests of the community as the people who lived in that community, and when the assent and the consent of the surrounding districts were received why should Parliament interfere?—The resolution was adopted.

A resolution urging the promotion of legislation to carry out the recommendations in the report of the Water Gas committee of 1899 was then adopted.

Resolutions on the subject of the easier acquisition of land by local authorities, the simplification of the law relating to the creation and issue of stock, and for the amendment and consolidation of the Public Health Acts having been approved,

The PRESIDENT moved—

1. That enterprises which have hitherto been entrusted by Parliament to municipal corporations, such as gas, water, tramway, electric lighting and power, markets, docks, piers, and other similar undertakings, have been managed efficiently and economically, and for the general benefit of the inhabitants of the localities, and any abridgment or interference with such powers would, in the opinion of this meeting, be a misfortune to the communities severed by such undertakings and a retrogade step in the principles of local self-government.

3. That municipal corporations cannot exercise any trading or other powers beyond those authorised by the general or local Acts. That it is inexpedient to fix a limit to the powers to be granted in future to municipal corporations, and that each case should be dealt with on its own merits.

4. That having regard to the fact that the town council is a representative body, and that manufacturers and traders are members of such council, or are fully represented thereon, there is no fear that any undue interference with the trading interests of any town will be proposed or carried out.

The Lord Mayor of Dublin proposed as an addition—

"That any legislation which imperils the principle contained in the foregoing resolution be opposed by the association."

He thought that in view of the unfriendly attitude of the House of Commons it would be well to have the proposed rider added to the resolutions. The resolutions were adopted with the addition of the suggested rider.

Nice.—Electric tramways have now been substituted for the old horse-driven cars throughout the tramway service in Nice, the work being carried out by the Thomson-Houston Co. The tram lines have been extended to Villefranche, and will ultimately be extended to Monte Carlo. While the trolley wires for the electric tramways are run overhead on the greater portion of the system, the importance of the main Avenue de la Gare and some other of the main thoroughfares traversed by the huge cars which form a feature of the flower carnival has necessitated the placing of the tramway wires underground. The importance of the Nice carnival from a commercial point of view has been held to justify the municipal authorities in imposing conditions upon the tramway company calling for this modification of the overhead system.

The electric tramway at Cannes, in the same district, has been extended to Antibes and also to Vallauris by a branch at Golfe Juan. The venture has proved a considerable pecuniary success, notwithstanding that the company has had to hand over to the State £2,600 to enable the authorities to overcome the interruption to the telephone system caused by the overhead trolley lines.

Pemberton.—Mr. James Ashurst, chairman of the Electric Lighting and Tramways committee of the Town Council stated at a meeting of his constituents that the Council would shortly become owners of the tramway lines, and unless the company now working them agreed to substitute electricity for their horse-driven cars no renewal of their lease would be granted. He strongly recommended the adoption of electric lighting, for which the Council has recently obtained a provisional order. He hoped that "free wiring companies would be permitted to come into the district and wire buildings for the electric light, or that a local company would be formed to carry out this part of the work."

Pietermaritzburg (Natal).—A bill before the Natal Parliament, introduced by the Corporation of this town, seeks power to construct electric tramways within the borough at an estimated cost of £75,000.

St. Helens.—The Parr-Derbyshire Hill electric tramway route was officially inspected on behalf of the Board of Trade on Wednesday.

Shoreditch (London).—It is fifteen months since the London County Council were requested to grant a loan of £67,783 for the Hoxton generating station of the Vestry, and the local members of the Council are to be invited to exert their influence in facilitating the granting of the loan.

South Africa.—Messrs. Siemens Bros. and Co. (Ltd.) have already shipped 1,000 iron poles to be used in the re-erection of land lines damaged during recent hostilities.

Southampton.—Sanction has been obtained for the borrowing of £50,655, out of £55,000 applied for for electric lighting extensions.

South Shields.—A proposal to increase the salary of the borough electrical engineer (Mr. J. A. Jeckell) from £350 to £400 per annum has been deferred for six months.

Stourport.—An application by the Kidderminster and District Electric Lighting and Traction Co. for the Council's sanction to a provisional electric lighting order has been referred to the General Purposes committee.

Sunderland.—A petition has been presented to the Lighting committee for a reduction in the price per unit of electric current, and to abolish the maximum demand system of charging.

Swansea.—The charge for current for private lighting has been fixed at 6d. per unit for the first 1½ hours' maximum demand, and 2d. after. For motive power the charge for the first hour's maximum demand will be 6d. per unit and 1½d. after, or alternatively a uniform rate of 3d. per unit. The Electric and Tramways committee have also decided to supply current on the prepayment meter system. Meters for 1d., 6d., or 1s. in the slot are to be provided, and the price to be charged for current is to be fixed on such a basis as, if necessary, to cover the amount which would become payable to the National Electric Wiring Co., and also the maintenance of the meter, cost of collection, &c. It is proposed to obtain powers to extend the area of lighting to comprise the whole of the borough.

Tottenham.—At a special meeting of the District Council a motion pledging the Council to oppose the North Metropolitan Electric Power Supply Bill was discussed. The following resolution, passed by the Edmonton District Council, was submitted to the meeting and approved:—

With a view to the economy in the generation of electrical energy for power, heating and lighting purposes, this Council is prepared in the next session of Parliament, jointly with the other local authorities, or with the Middlesex County Council, or both, to promote a Bill in Parliament or a Provisional Order (if the object can be effected in that way), for the purpose of enabling the local authorities in the northern and eastern portions of Middlesex, either jointly by themselves or with the Middlesex County Council, to acquire land and generate electrical energy for the purpose of distributing the same in bulk, and for other purposes in which such local authorities and the Middlesex County Council may have a common interest.

A conference of representatives of Hornsey, Tottenham, Southgate, Wood Green, Friern Barnet, and Edmonton was held yesterday

Digitized by Google

(Thursday) to discuss details and to organise the opposition to the North Metropolitan Bill after the promoters' case has been completed before the Parliamentary Committee on the 19th inst.

Tramways in London.—The St. James' (Westminster) Vestry are advised to oppose the proposal of the London County Council to construct tramways from the present terminus, Theobald's-road, to Piccadilly-circus, on the ground that a tramway terminus at Piccadilly-circus would cause great congestion of traffic. Cambridge-circus (near the Palace Theatre) is suggested as a suitable terminus.

Tunbridge Wells.—The Council having received a licence to establish a municipal telephone service a report by the Telephone committee, presented at Wednesday's meeting, stated that No. 5, Calverley-parade, had been acquired as a site for the central exchange. The consulting telephone engineer (Mr. A. R. Bennett) had informed them that he was satisfied the estimate he had submitted was sufficient to establish a telephone service; that the inclusion of Crowborough, Withyham, and Mayfield within the Corporation area and the provision of a service for those villages and the subscribers resident there would necessitate an increase of £1,010; that the great success which had attended the Corporation's canvass for subscribers rendered it desirable that partial provision should at once be made for another 100 subscribers, the cost of which he estimated at another £800, making, with his original estimate of £7,119, a total initial expenditure of £8,929. These recommendations were endorsed by the committee. The area has been extended so as to include the parishes mentioned. The committee recommended the Council to authorise them, provided the amount of the tenders which the Council had given them authority to obtain did not materially exceed the amount of Mr. Bennett's estimate, to accept such tenders and proceed with the work without delay. The committee further recommended that authority to borrow £10,000 be obtained. The report was adopted.

Councillor Robb, in presenting the report of the Electric Lighting committee, said that another £10,000 would be required to meet the additional expenditure for electric lighting. The new chimney at the electricity works was estimated to cost £2,500, the new engine £4,600, boiler £1,600, and £1,300 was required for development contingencies. The profit on last year's working amounted to £748. 14s. 10d. It was decided to consult Sir W. H. Preece, and meanwhile to refer the report back.

Wigan.—The chairman of the Electric Light and Tramways committee (Mr. Worthington) announced, on Wednesday, that electricity supply would probably be available in the autumn.

Wood Green (London).—The Light Railway committee of the District Council has been re-named the Electrical committee and has been instructed to prepare an early report on the subject of electric lighting for the district.

Workhouse Lighting.—The House committee of the Kidderminster Guardians are considering a proposal to substitute electric for gas lighting at the workhouse.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

TENDERS INVITED.

Shoreditch (London) Vestry require tenders for the supply of eight dry-back marine-type boilers, or eight water-tube boilers, with automatic stokers, and sundry ironwork for their new generating station at Whiston-street. Specification may be obtained at the office of the electrical engineer (Mr. C. Newton Russell), Electric Light Station, Coronet-street, Hoxton, N., and a copy of the specification may be inspected (but not obtained) at the offices of the consulting engineers (Messrs. Kincaid, Waller and Manville), 29, Great George-street, Westminster. Tenders to Dr. H. Mansfield Robinson, vestry clerk and solicitor, Town Hall, Old-street, E.C., before noon on 19th inst. An advertisement contains further particulars.

Dudley Corporation invite proposals for wiring premises in the district on the free or easy wiring system. Particulars are set out in an advertisement, and specification, &c., may be obtained from the consulting engineer (Mr. Reginald P. Wilson), 66, Victoria-street, Westminster, S.W. Tenders to town clerk (Mr. H. C. Brettell), Town Hall, Dudley, by 15th inst.

The directors of the *Highland Railway Co.* invite tenders for stores for six and twelve months from July 1. The company's requirements include telegraph instruments and fittings, telegraph construction material, copper and brass tubes, screws, galvanised steel and iron wire, &c. Further particulars are set out in an advertisement, and forms of tender may be obtained from the stores superintendent (Mr. C. Kennedy), Inverness. Tenders must be lodged with the secretary (Mr. Wm. Gowenlock), company's offices, Inverness, by Saturday, the inst.

Bury Corporation invite tenders for the wiring of the Art Gallery and Free Library. Tenders to the town clerk (Mr. John Hasham), Corporation Offices, Bank street, Bury, by 18th inst. Particulars are given in an advertisement.

London County Council require tenders for the supply (within three months of order) of about 70 arc lamp standards for the lighting of the Victoria Embankment. Further particulars are set out in an advertisement, and specification, &c., can be obtained after 13th inst. at the engineer's department, County Hall, Spring-gardens, S.W. Tenders to clerk (Mr. C. J. Stewart), by 10 a.m. July 10.

London County Council's Asylums committee invite tenders for the installation of electric lighting and power (except generating plant) and the installation of telephones, tell-tale clocks, fire alarms and call bells at the Horton Asylum, near Epsom, Surrey. Tenders to the committee, 6, Waterloo-place, S.W., by 10 a.m., June 16.

Durban (Natal) Corporation require tenders for overhead equipment for about 16 miles of equivalent single track. Tenders to Messrs. Webster, Steel and Co., 5, East India-avenue, London, E.C., by June 29, or to the town clerk of Durban by mail delivery on or about Monday, July 23.

The Electric Lighting committee of the *St. Mary, Newington* (London) Vestry require tenders for the supply and laying of insulated electric mains, conduits, junction boxes, &c. Tenders to the vestry clerk (Mr. L. J. Dunham), Vestry Hall, Walworth, S.E., by noon 15th inst.

The Vestry of St. Mary Magdalene *Bermondsey* (London), require tenders for the supply and laying of insulated electric mains, conduits, junction boxes, &c. Tenders to Mr. Fred Ryall, vestry clerk, Town Hall, Bermondsey, before noon of June 18.

Glasgow Corporation require tenders for outside coal storage and steel structure for coal handling, and locomotive travelling cranes for outside coal handling, for their Pinkston power station. Tenders to the town clerk (Sir J. D. Marwick) by 5 p.m. on 21st inst.

Kingston-upon-Thames Corporation require tenders for excavations and concrete foundations of boiler house extensions, &c., at the electricity works. Tenders by 15th inst.

Bradford Corporation require tenders for a switchboard, or for alterations to existing switchboard, at the Valley-road electricity works. Tenders to the town clerk (Mr. Frederick Stevens) by June 14.

Stockport Gas and Electricity committee require tenders for two water-tube boilers for their Millgate electricity station. Tenders to chairman of committee by 13th inst.

Blackpool Corporation invite tenders for the electrical equipment of 15 single truck tramcars. Tenders to borough electrical engineer (Mr. Robt. C. Quin) by 18th inst.

Sutton Coldfield Corporation invite tenders for electricity generating plant. Tenders to town clerk before noon of June 21.

Sutton Coldfield Corporation require tenders for the erection of electricity station buildings. Tenders by noon 26th inst.

Bootle Corporation invite tenders for supply and laying of underground electric cables, erection of arc lamps, and the supply of mechanical stokers. Tenders to town clerk before June 16.

Croydon Corporation require tenders for engine foundations and for joists and flooring, and also for coal, at electric light stations. Tenders by 14th inst.

Newcastle-on-Tyne Tramways Committee invite tenders for the erection of the new generating station and chimney shaft. Applications to Mr. B. F. Simpson, 12, Gray-street, by 10th inst.

Nelson Corporation require tenders for a storage battery and a switchboard. Tenders to town clerk by June 12.

Tenders are invited for wiring the *Derby* Infectious Diseases Hospital. Tenders by 9th inst.

Tenders are invited for the supply of 300 tons of copper wire for the *French* Telegraphs. Tenders to Le Sous-Secretariat d'Etat des Postes et des Telegraphes, 103, Rue de Grenelle, Paris, by 19th inst.

Tenders are invited until July 7 for the concession for the construction of an electric tramway from *Puerta de Hierro* to *Aravaca y Pozuelo* (*Madrid*).

The municipal authorities of *Ribadavia* (Orense), Spain, invite tenders for the concession for the electric lighting of the town for 20 years. Particulars from el Secretario del Ayuntamiento, and tenders by July 2.

The Central Administration of Ports and Lighthouses, *Alexandria* (Egypt) require tenders for generating plant for the electric lighting of the Port Said lighthouse. Tenders to Controller-General by noon, July 1.

TENDERS RECEIVED AND ACCEPTED.

Hampstead (London) Vestry has accepted tenders from Messrs. Siemens Bros. and Co., W. T. Henley's Works Co., W. T. Glover and Co., and the British Insulated Wire Co. for the supply of electric lighting cables at schedule prices. The tender of Messrs. Cooke and Co. for the supply of Bwllfa best coal to the electricity station at 27s. 1d. per ton for nine months from July 1 has also been accepted.

Digitized by Google

Southampton Corporation have received the following tenders for the supply of a 300 kw. continuous-current generator, coupled direct to medium-speed vertical compound engine. The speed of the engines in (I.) are all at 180 revs., except the British Schuckert Co. (125) and Mather and Platt (120) :—

(I.)—*Combined Plant with speed limited to 180.*

		Delivery in

Croydon County Council has accepted the tender of Mr. S. Page for erecting a sub-station adjoining the tramway depôt at Thornton Heath for £317. 10s.

APPOINTMENTS VACANT AND FILLED.

The post of senior demonstrator in the department of electrical engineering and applied physics at the City and Guilds Technical College, Finsbury, will be vacant at the close of the present session. The salary is £150, rising to £200. Applications for the post have to be addressed, in the first instance, to the principal of the college, Leonard-street, Finsbury, London, E.C., by June 29. An advertisement gives some further particulars.

Birmingham Corporation require two lecturers for the electrical and engineering departments of the municipal technical school in September next. An advertisement contains further particulars, and applications must be sent to the secretary (Mr. Geo. Miller), Suffolk-street, by 30th inst.

The Council of the Municipal Electrical Association require a secretary to act under the direction of the honorary secretary. Applications to the president (Mr. A. B. Mountain, borough electrical engineer, Huddersfield), by 14th inst. An advertisement contains additional particulars.

The Council of the King's College, London, invite applications for the post of demonstrator in electrical engineering. Conditions of the appointment can be obtained of the Secretary, and applications must be in by 30th inst. See advertisement.

Whitechapel District Board of Works require a mains foreman and also a plumbing jointer. Particulars are given in an advertisement, and applications must be sent to the engineer, 27, Osborn-street, London, E.

A youth is required as tester on mains and house wiring in the electricity department of the Poplar District Board of Works. Applications to Mr. A. Blackman. See advertisement.

Tottenham Polytechnic committee require a teacher of physics and chemistry for evening classes for 1900-1901 session. Applications by 20th inst.

An assistant master (for physics and mathematics) is required for the Day School of Science, Gravesend. Applications by 21st inst.

A head master is required for the day school of the Birmingham Municipal Technical School. Applications by 30th inst.

A shift engineer is required at Blackburn Corporation electricity works. Applications by 9th inst.

An engineer and manager is required for the Stafford electricity and gas works. Applications by 16th inst.

Mr. J. Gray Scott, borough electrical engineer at Whitehaven, has been appointed to the position of burgh electrical engineer at Leith, in succession to Mr. W. A. Bryson, resigned, by 11 votes to 4. A proposal to re-appoint Mr. Bryson was lost.

Mr. W. T. A. Emtage, Principal of the Wandsworth Technical Institute, has been appointed Director of Public Instruction in Mauritius.

Shrewsbury Corporation have appointed Mr. Stephen Kirkwood of the Lancaster Corporation Electricity Works, chief assistant electrical engineer. Thirty-four applications were received.

Mr. A. Nichols Moore, of the Blackpool and Fleetwood Tramroad Co., has been appointed an assistant engineer of the Sheffield Corporation tramways.

Mr. F. J. Jeffs, a student at Mason College, Birmingham, has been appointed second assistant in the Physics Department, Municipal Technical School, Blackburn.

We announced on May 25 that the applications for the post of burgh electrical engineer at Greenock had been reduced to a short leet of seven. The names are H. Foster (Dover), H. L. Howard (Leicester), E. Marples (Liverpool), J. Gray Scott (Whitehaven), H. R. Forbes Mackay (Edinburgh), W. M. Nelson (Greenock), and R. W. L. Phillips (Bristol). On Monday the Electricity committee further reduced the short leet to the three last mentioned. The appointment will be definitely filled by the Council at its meeting on Monday next.

Scholarships.—Two Bowen Research scholarships in engineering and one in metallurgy, and three Priestley scholarships in chemistry, at the Mason University College, Birmingham, will be awarded in September next. The annual value is £95 each, and applications must be sent to the registrar by June 30.

BUSINESS NOTICES.

Messrs. W. T. Glover and Co. (Ltd.) notify their new address to be Trafford Park, Manchester.

Mr. T. M. Harvey, whose resignation was announced in our issue for May 25, has rejoined the staff of Johnson and Phillips' Electric Cable Works.

BANKRUPTCIES, LIQUIDATIONS, &c.

Geo. Herbert Bentley, electrical engineer, 63, Cross-lane, and 8, Grafton-street, Earlestown, has been adjudicated bankrupt. The first meeting of creditors takes place 15th inst. at the O.R.'s, Byrom-street, Manchester, and the public examination on July 6 at the Court House, Palmyra-square, Warrington.

A receiving order has been made against W. Hirst (trading as Hirst and Co.), electrical engineer, St. Leonard's-road, West Croydon, on his own petition.

Sale by Tender.—Leeds Corporation are open to receive tenders for two horizontal Fowler engines of 400 I.H.P., two sets of Greenwood and Batley dynamos, one spare armature to fit any dynamo, and a switchboard and instruments, the plant being at present in use in connection with the Corporation's system of electric tramways. Particulars will be found set out in an advertisement elsewhere, and it is notified that the plant will be available for removal about February next. Further information can be obtained from Messrs. Hopkinsons and Talbot, 26, Victoria-street, London, S.W.

Messrs. H. N. Newton and Co. will sell by auction, at Epsom Downs, on Tuesday next, at 12 o'clock, four Jackson 2 H.P. and 4 H.P. electric motors on sliding rails, with nearly new 270 ampere Jackson dynamo, switchboards and fittings, and complete electric apparatus, with arc lamps, &c., used in the business of a collotype printer. Particulars of the auctioneers, 67 and 69, Chancery-lane, London, W.C.

For Sale.—A leasehold factory and about 4 acres of land, situated in Essex, and about 12 miles from London, together with tools and plant and surplus stock, are offered for sale by private tender. Further particulars are set out in an advertisement. Tenders must be sent (by June 19) to Messrs. Sydney Lee and Co. (Ltd.), 9, Furnival-street, Holborn, London, E.C., from whom forms of tender and conditions of sale may be obtained.

Fire.—On Thursday, last week, a fire occurred at 82, Victoria-street, London, S.W., which spread to the laboratory of the Nernst Electric Light Co. (Ltd.), and considerable damage was done. Nearly all the special apparatus was destroyed, and some delay must occur before the company can replace it. The company has, however, already started work again.

B.T.H. Plant.—Circular No. 32 issued by the British Thomson-Houston Co. is devoted to overhead trolley-line construction and materials therefor. A large variety of these goods are dealt with. Circular 65 describes automatic circuit breakers.

"Ark" Lamps and Accessories.—Messrs. Johnson and Phillips have ready an exceptionally well-illustrated catalogue of J. and P. "Ark" lamps and arc lamp accessories. As this firm were amongst the earliest makers of arc lamps, they urge that 20 years' success in this branch of manufacture entitles them to be heard on matters dealing with arc lamp illumination. More than usual attention has been given to the compilation of the particulars included in the catalogue, the whole of which will be found of service to consultants, installation contractors, municipal committees, engineers and others indenting for these goods. A choice selection of lamp pillars and wrought-iron brackets is added. Messrs. Johnson and Phillips in introducing this new enclosed long-burning lamp claim many advantages for it, and inform us they have built and equipped with all the most modern machinery special shops for its manufacture. The lamps are being made in large quantities for every class of illumination where enclosed arc lamps are suitable, thereby effecting economies in the cost of manufacture which will enable the makers to place the lamp on the market at prices calculated to meet the severe competition of both home and foreign-made lamps. Most of the lamps and accessories here illustrated are of special design, and the illustrations are in many cases in colours, from photographs direct from the lamps. Accompanying the catalogue is a lengthy list of testimonials from installers and users of J. and P. "Ark" lamps, all of which are of a most flattering character. We illustrate in Fig. 1 a J. P. "Ark" lamp fitted with a strong black japanned case; in Fig. 2 the lamp with case removed, showing entire absence of clockwork, rods, levers, chains, telescoping and other contrivances, and in Fig. 3 the inner globe of simple, inexpensive form. We have selected the lamp shown in Fig. 1 because it is that designed for general use. Some of the other lamps shown in the new catalogue are of more artistic exterior.

J. & P. "ARK" LAMPS.

COMPANIES' MEETINGS AND REPORTS.

Telegraph Manufacturing Co. (Ltd.).

The ordinary general meeting of the shareholders of this Company was held on Thursday last, at Liverpool, Mr. JAMES TAYLOR, chairman of the Company, presiding.

The CHAIRMAN, in moving the adoption of the report and accounts, said it was a great pleasure to the directors to meet the shareholders with such a satisfactory increase in their business and profits. Their gross profit for the past year amounted to £41,284, an increase of £13,012 over the previous year. Their property and assets, including goodwill, had also increased from £127,142 to £145,870 in consequence of extended works, and the purchase of 10 acres of land adjoining their works and the railway at Helsby, which they believed would prove a very valuable acquisition. After deducting depreciation, which was off prime cost, the total of their plant and buildings, &c., now stood at £138,842. The stock-in-trade stood at about £84,000, which was rather large, but was necessitated by the frequent demands for immediate supply. They had a large stock at the Cape, of which they hoped to be able to dispose quickly, now that hostilities were ceasing. Out of the balance at their disposal they proposed to add £3,887 to depreciation account, and £17,500 to reserve, increasing that fund to £27,500, which on a capital of £200,000 was not bad for a company with practically less than two years' working. There was also £4,883 for preference dividend, and in addition to an interim dividend of 3s. per share they now proposed the payment of 7s. per share and a bonus of 2s., making in all 12 per cent. for the year on the ordinary shares. This satisfactory result had been brought about by the loyal co-operation of all the staff.

Mr. CROSLAND TAYLOR seconded the resolution, which was unanimously agreed to.

A special meeting followed at which the CHAIRMAN moved: "That the capital of the Company be increased to £300,000 by the creation of 20,000 additional ordinary shares of £5 each, ranking for dividend and in all other respects with the existing ordinary shares of the Company." The immediate issue he said would be 5,000 shares at a premium of £4 per share, the existing shareholders to have the first option of taking them up. The amount of the premium—£20,000—would be added to reserve. The increased capital was required through the large and rapid extension of the business of the Company. The resolution was carried unanimously.

A hearty vote of thanks to the chairman and directors closed the proceedings.

BELLISS AND MORCOM (LTD.)—The directors' report for the year to March 31 last states that after charging interest on the purchase money and debentures, making ample reserves for depreciation, &c., writing off from goodwill the apportioned amount of profit to May 5, 1899 (the date of the agreement for purchase), and providing for the preference dividend paid to March 31, 1900, the accounts show an available balance of £30,203. 6s. 9d., which it is proposed to appropriate as follows : Dividend at the rate of 10 per cent. per annum on the ordinary shares, free of tax, £9,044. 13s. 9d. ; reserve, £10,000 ; preliminary expenses written off balance, £1,046 ; carried forward, £10,112. 13s. The works have been fully occupied during the past year, and new buildings are being equipped with machinery and brought into use as rapidly as possible to deal with orders in hand.

CHADBURN'S (SHIP) TELEGRAPH CO. (LTD.)—The report of the directors for the year to March 31 states that the balance at credit of profit and loss is £11,361. Deducing proportion of profits due to vendors to completion of purchase and other expenses, depreciation, &c, there remains £7,904, from which £5,400 is deducted for dividends of 6 per cent. per annum on the preference and an interim dividend of 6 per cent. per annum on the ordinary shares, leaving £2,504. The directors propose a dividend on the ordinary shares of 8 per cent. per annum for the half year, making 7 per cent. for the year, leaving £536 to be carried forward.

MICA MANUFACTURING CO. (LTD.)—At the meeting of the shareholders, held last week, the chairman (Mr. Alfred E. Ann) stated that the demand for mica, especially of small size, for the first time in the history of the company rendered a large number of waste heaps of mica at the company's various mines a really valuable asset, and the company was at present working at four or five of these heaps casting the material away as fast as it could be taken, and selling at a good profit. They were employing 75 people, and the company's prospects were in all respects satisfactory. Sir Samuel Canning has resigned his directorship of the company.

NEW COMPANIES, STATUTORY RETURNS, &c.

H. AND H. ACCUMULATOR SYNDICATE (LTD.)—This company was registered on May 31, with a capital of £10,000 in £1 shares, to carry on the business of manufacturers of and dealers in primary batteries, storage batteries, locomotives, rolling stock and electrical apparatus, fittings and appliances of every description, and to enter into an agreement with Charles Bright and Co. (Ltd.).

AUTOMOBILE MANUFACTURING CO. (LTD.)—This company was registered on April 30 with a capital of £100 in £1 shares, to acquire the business carried on by W. C. Bersey, and the business carried on by Messrs. Townsend and Bizzey, and to carry on the business of motor car builders, electrical and general engineers, &c. The subscribers are W. C. Bersey, E. Townsend, H. S. Wyndham, A. E. Bizzey, S. Lambert, H. Webster, and A. A. Brown.

BRITISH AND GENERAL PUBLIC WORKS CONSTRUCTION CO. (LTD.)—This company was registered on May 21, with a capital of £1,000 in £1 shares, to carry on the business of railway and tramway proprietors, and electrical and mechanical engineers, &c.

BRITISH MOTOR TRACTION CO. (LTD.)—This company was registered on May 14, with a capital of £100 in £1 shares, to carry on the business of electrical, steam, oil and other motor manufacturers, tramway proprietors, &c.

CHARING CROSS AND CITY ELECTRIC CO. (LTD.)—This company was registered on May 28, with a capital of £300,000 in £5 shares (20,000 preference), to carry on the business of electricians, electrical and general engineers, suppliers of electricity for light, heat, motive power and other purposes, wire drawers, &c. ; to construct and maintain electrical works, plant, machinery and apparatus, and to promote the use of electricity generally. The subscribers are W. F. Fladgate, 2, Craig's-court, Charing Cross, S.W., chairman Charing Cross and Strand Electric Supply Corporation (Ltd.), 200 shares ; G. H. B. Glasier, 7, St. James's-street, S.W., director ditto, 200 shares ; S. Gatti, Adelaide Gallery, Strand, director ditto, 200 shares ; R. Chadwick, 34, 35, St. Martin's-lane, W.C., director ditto, 200 shares ; J. M. Gatti, Adelaide Gallery, Strand, director ditto, 200 shares ; G. W. Finch, 22, Queen Anne-street, W., solicitor, 1 share ; R. Gatti, 10, Bedford-square, W.C., merchant, 1 share. The first directors are William F. Fladgate, George H. B. Glasier, Stefano Gatti, Richard Chadwick and Joannes M. A. Gatti.

T. COULTHARD AND CO. (LTD.)—This company was registered on May 8, with a capital of £75,000, in £1 shares, to acquire the business of T. Coulthard and Co., Preston, and to carry on the business of electrical and mechanical engineers, motor vehicle manufacturers, &c.

SCOTTISH ELECTRICAL LUMINCRIPTOR CO. (LTD.)—This company has been formed with capital of £10,000 in £1 shares. The first directors are Sir Henry Wardlaw, William Bow, R. Peacock, and Edward Scott.

BROCKIE-PELL ARC LAMP (LTD.)—The annual return to April 23 gives the capital as £80,000 in £1 shares, 79,965 of which have been taken up. £1 has been called up on each of 25,620, and £25,606. 17s. 6d. has been received, leaving £13. 2s. 6d. in arrears. 54,380 shares are considered as fully paid.

CHELSEA ELECTRICITY SUPPLY CO. (LTD.)—The annual return to March 21 has been filed. The capital is £400,500 in 74,000 ordinary and 6,000 preference shares of £5 each and 500 founders' shares of £1 each, of which all the preference and founders' and 34,000 ordinary have been taken up. £5 has been called up on each of £27,334 ordinary and 6,000 preference and £166,670 has been received.

DIRECT SPANISH TELEGRAPH CO. (LTD.)—According to the annual return to April 10, the capital is £95,000, in 13,000 ordinary and 6,000 preference shares of £5 each, of which 12,931 ordinary and 6,000 preference have been taken up.

LONDON ELECTRIC SUPPLY CORPORATION. (LTD.)—The annual return to April 11 has been filed. The capital is £850,000, in 200,000 ordinary shares of £3 each and 50,000 preferred shares of £5 each, of which 111,000 ordinary and 49,840 preference have been taken up. £585,940 has been received, including £3,740 paid on 1,950 forfeited shares.

NATIONAL ELECTRIC WIRING CO. (LTD.)—The annual return to April 16 gives the capital as £250,000 in £1 shares, 118,971 of which have been taken up. 12s. 6d. has been called on each of 100,120 shares. 18,851 shares are considered as fully paid.

TELEGRAPH CONSTRUCTION AND MAINTENANCE CO. (LTD.)—The annual return to March 13, gives the capital as £448,200, in 37,350 shares of £12 each, all of which have been taken up and paid for in full.

WILLANS AND ROBINSON (LTD.)—The annual return to April 25 has been filed. The capital is £500,000 in 50,000 preference and 50,000 ordinary shares of £5 each, of which 40,000 preference and 40,000 ordinary shares have been taken up. £5 per share has been called up on 15,337 and £3 per share on 10,000 preference, and £5 has been called up on each of 15,538 and £3 on each of 10,000 ordinary shares. £215,375 has been received.

CITY NOTES.

MEMORANDA.—Bank rate 3½ per cent. (since May 24, 1900). Price of silver 27⅝d. per oz. (June 7). Consols (2¾ per cent.) 101 1/16—101 3/16 for money, 101⅛—102 for account; 2½ per cent. 99½—100 (June 7). Stock Exchange Settling Day: Consols, July 4; Stocks and Shares Continuation Days, June 12 and 26; Ticket Days, June 13 and 27; Pay Days, June 14 and 28; Mining Share Carry-over Days, June 11 and 25.

COMMERCIAL CABLE CO.—A quarterly dividend of 1¾ per cent. has been declared payable on 2nd July. The transfer books will be closed from 20th inst. to 2nd July inclusive.

CRYSTAL PALACE DISTRICT ELECTRIC SUPPLY CO. (LTD. AND REDUCED).—On July 7 a petition for reducing the capital of this company from £100,000 to £74,272. 12s. (by the cancellation of 18s. per share upon each of 28,586 shares of £1 each) is to be heard before Mr. Justice Kekewich.

ISLE OF MAN TRAMWAYS AND ELECTRIC POWER CO. (LTD.)—It is stated that the proceedings of the committee of investigation into the affairs of this company have come to a standstill, owing to a dispute with the directors as to the proper course to be pursued in order to extricate the company from its embarrassments.

MUNICIPAL LOAN.—Plymouth Corporation is inviting subscriptions to an issue of £250,000 3 per cent. redeemable stock at a minimum price of £95 per cent. The money is required for (amongst other improvements in the town) the extension and electrical equipment of the tramways. The first six months' interest is to be paid September 30 next.

NATIONAL ELECTRIC SUPPLY CO. (LTD.)—It is intended to pay off the debentures of this company on the 1st September. Debenture holders are to have the option of exchanging their debentures for £4 per cent. cumulative preference shares.

STOCK EXCHANGE NOTICES.—The London Stock Exchange Committee have appointed June 13 a special settling day in a further issue of 10,579 ordinary £10 fully-paid shares (Nos. 100,001 to 110,579) in the *City of London Electric Lighting Co. (Ltd.)*, and have ordered these and a further issue of 20,000 6 per cent. £5 fully-paid preference shares (Nos. 54,001 to 74,000) in the *New General Traction Co. (Ltd.)* to be quoted in the Official List. Application has been made to the committee to appoint a special settling day in and to grant a quotation to the £125,000 4½ per cent. debenture stock of the *Potteries Electric Traction Co. (Ltd.)*, and 40,000 £5 shares of the *Johnson-Lundell Electric Traction Co. (Ltd.)*.

NOTES.

WE are glad to see that steps are being taken to obtain unanimity among manufacturers of cable for electrical purposes on the question of conventional standards for the weight and resistance of copper. As we pointed out last December, the arbitrary standards arrived at by the "Committee on Copper Conductors" were of no avail unless all the manufacturers of cable had a voice in their selection and undertook to abide by them. At that time the two largest manufacturers of electric light cable stood out from the combination, but, since then, the informal association of rubber cable manufacturers has been developed into a "Cable Makers' Association," and these two firms and, in fact, practically all the cable manufacturers in this country have joined it. The report of the committee above referred to is still under discussion by a sub-committee of the Association, which will meet in about ten days' time to prepare its report, and at a meeting of the Association in three or four weeks from now a definite decision will probably be arrived at. The outcome of the deliberations may be expected to be the adhesion of the Association to the conventional standards for copper resistance and weight specified in the original report of the "Committee on Copper Conductors," but a modification of the rule for the resistance and loss in lay of stranded conductors.

IT is to be regretted that Prof. FORBES and Prof. PERRY should discuss their differences in such an unfriendly spirit, for both have published figures and investigations of two kinds—those of practical value and others of purely academic interest. By concentrating their attacks on one another's contributions of the latter class the two professors have, in the discussion on Prof. FORBES' Paper, and subsequently in our correspondence columns, left it to be inferred that the accuracy or utility of the whole is at fault in each case; whereas there is no doubt that neither Prof. FORBES' tables nor Prof. PERRY's methods are entirely devoid of practical bearing. An illustration of the manner in which the professors are at cross-purposes is given by one of the numerical examples they have chosen. Prof. PERRY says that in a simple transmission system without line boosters, or in a single section of a boosted system, the efficiency *cannot* be less than 50 per cent. Prof. FORBES says it *can*, because if a generator delivers 1,000 volts to a line of 3 ohms resistance, and if 200 amperes be utilised at the other end, the loss in pressure will be 600 volts and the efficiency 40 per cent. No doubt this *can* be done, but Prof. FORBES does not need the unwilling services of Mr. SWINBURNE as "foolometer" (see our Correspondence columns this week) to know that no one but a fool would do it, when to transmit the same 80 kw. at the far end with only 50 per cent. loss, a lighter line of 3⅛ ohms resistance would suffice, with a current of 160 amperes.

THE sensational announcements in the American press with regard to Mr. NIKOLA TESLA's wonderful doings and still more wonderful prophecies, have been attributed in a large measure to the highly developed power of imaginative embroidery possessed by some Western newspaper reporters. An article by Mr. TESLA himself, in the current number of the *Century Magazine*, shows that an injustice has been done to that class of individuals, for this contribution equals in wild speculation anything hitherto attributed to the eminent inventor. The article is headed "The Problem of Increasing Human Energy, with Special Reference to the Harnessing of the Sun's Energy." The writer begins by postulating that human life is a movement. The existence of a body in motion unavoidably implies a force which is moving it. Consequently Mr. TESLA chooses to consider human energy as denotable by the expression $MV^2/2$, and proceeds to consider how it may be increased. M he takes as the "total mass of man in the ordinary interpretation of the term 'mass,'" and V is "a certain hypothetical velocity." He warns his readers against reducing their mass by intemperance, impure drinking water, or laxity of morals—digressing on the subject of food supply, and the production of artificial

Digitized by Google

fertilisers by causing the nitrogen of the air to combine chemically with the oxygen in a high-pressure electric discharge.

ORGANISED warfare, Mr. TESLA thinks, is what tends mostly to the reduction of the hypothetical velocity V, and he proceeds to describe a means, he has not yet perfected, of rendering warfare less harmful in this direction. This simple means is the substitution of "telautomatics" for men. So far he has only succeeded in constructing one such apparatus—a boat controlled by electrical oscillations—with a "borrowed mind"; but, he says "I purpose to show that, however impossible it may now seem, an automaton may be contrived which will have its 'own mind' and . . . be capable of distinguishing between what it ought to do and what it ought not to do. . . . . In fact, I have already conceived such a plan." On the other hand, to deal fully with the methods of increasing the force "accelerating the human mass" would lead Mr. TESLA too far. "Suffice it to state that the resultant of all these forces is always in the direction of reason. . ." A "telautomatic" is then presumably not one of the components.

LACK of space precludes us also from dealing more fully with Mr. TESLA'S dreams—or are they nightmares?—with their bright pictures of high-pressure phenomena. We can only mention briefly some of his schemes for the advantage of mankind. He intends to smelt iron by first electrolysing water, burning the hydrogen in air to produce the heat for smelting, and selling the pure oxygen as a by-product. He suggests other methods than windmills of obtaining energy from "the ambient medium," some of which he no longer considers likely to be commercially profitable, and others with regard to which he is more hopeful. He next deals with the transmission of energy through space without wires. The proposal to transmit electricity at high pressure through the upper strata of the atmosphere we have alluded to on a former occasion, but the following bears repetition. Mr. TESLA has discovered causes of error in HERTZ'S researches, with the result that he has "long ago ceased to look upon his [HERTZ'S] results as being an experimental verification of the poetical conceptions of MAXWELL."!

THE electrical department of the Whitechapel Board of Works is sparing no pains to solicit the patronage of the smaller consumers in its district. Not content with issuing a pamphlet setting forth the advantages and comparative cheapness of electric light, it has gone so far as to publish a "Yiddish" edition of it, printed in Hebrew characters, for the benefit of the large Jewish population of Oriental London, "many of whom," Mr. TAPPER humorously points out to us in the letter accompanying the pamphlet, "cannot read English, and to whom it would otherwise be extremely difficult to explain the maximum demand system of charging." The translation must have been done by a Yiddish scholar of no mean ability, whose appreciation of the technicalities of the subject is also complete. We might suggest in the way of friendly criticism, however, that although the definition of a demand indicator is clearly expressed in simple language, those who are not sufficiently educated to read English would experience a difficulty in understanding the word motor even when spelt phonetically in Yiddish, and that to them "Michaelmas" would not fix a season of the year so definitely as the phrase "Rosh-Hoshannah."

American Association for the Advancement of Science.—The forty-ninth annual meeting of this Association will be held in New York on June 23–30.

Electrical Engineers (R.E.) Volunteers.—Corporal A. Holdaway, of the above company, was reported "dangerously ill" at Bloemfontein, on the 9th inst.

Vacant Fellowship.—A research fellowship in pure and applied physics at Owens College, Manchester, of the value of £100 is offered. Further particulars are set out in an advertisement.

Institution of Electrical Engineers. Irish Section.—At a meeting of the Irish Section, held in Dublin last evening, Mr. R. Hammond delivered his postponed address on the "Proposed Dublin Electric Light and Power Scheme."

Boer Conservatism.—At Johannesburg, under a concession granted by President Krüger's Government, one-horse tramcars have been running for some time. A concession for the construction of electric lines has since been refused on the ground that "the farmers would lose the sale of their forage." The same objection has been raised to the cycle, upon which a heavy tax has hitherto been placed.

The English Electric Manufacturing Co.'s Works.—The new works of this company, at Preston (Lancs.), were formally opened yesterday. On the previous day the directors and officials of the company entertained a party of engineers, technical journalists, and others at a private view of these extensive and admirably-planned engineering works. We hope to present our readers with an illustrated description of the works in an early issue.

Improvements in Provincial Telephone Systems.—The new exchange in Bristol worked on the central battery system (described in *The Electrician*, Vol. XLIII., p. 401) is now in successful operation. The National Telephone Co. is laying underground wires both in Hull and Sunderland, and in both these towns the central battery system will probably be in operation within the next three months. In Hull it is replacing the branching system.

The Thames Steamboat Service.—A correspondent in *The Times* of Wednesday suggests that the difficulty in the way of the satisfactory working of the Thames steamboat service is not one of pier dues but arises from the inconveniently-placed points at which passengers take and leave the boats. He proposes, as a remedy, to provide stations in the main thoroughfares near the river, and to construct subways from these to the pier, conveying passengers through the subways to the pier by means of electric cars.

University Intelligence.—On Tuesday the Mathematical Tripos list was published at Cambridge. Mr. J. E. Wright, of Trinity College, is Senior Wrangler. After the reading of the list, honorary degrees were presented. Among the recipients were Sir Benjamin Baker, M. Henri Poincaré, and the Earl of Rosse. —At Oxford the Convocation has passed a statute providing that the occupant of the recently-endowed Wykeham Chair of Physics is chiefly to lecture on electricity and magnetism. The election of a professor has not yet taken place.

The Royal Society.—Among the Papers down for reading yesterday were the following:—"The Electrical Effects of Light upon Green Leaves (Preliminary Communication)," by Dr. A. D. Waller, F.R.S., "The Diffusion of Ions produced in Air by the Action of a Radio-Active Substance, Ultra-violet Light and Point Discharges," by J. S. Townsend, and "On an Artificial Retina and on a Theory of Vision," by Prof. J. C. Bose.—The Annual Soirée will be held at Burlington House, on Wednesday next, the 20th inst.

Aluminium Transmission Lines.—One of the chief features of the power transmission plant of the Snoqualmie Falls Power Co. (described in *The Electrician*, Vol. XLIV., p. 5, and also briefly referred to by Prof. Forbes, in his recent Institution Paper, *The Electrician*, May 10, p. 50), is the exclusive

Digitized by Google

employment of aluminium wire on the transmission line; and we read in the American papers that some trouble has recently been experienced in these lines owing to breakages. Heavier wire of a stronger alloy is now being erected between Tacoma and Snoqualmie Falls.

Cable Interruptions and Repairs:—

	Date of Interruption.	Date of Repair.
Latakia—Cyprus	June 21, 1899	—
Cayenne—Pinhieros	Oct. 11, 1899	—

Durban—Delagoa Bay	May 31, 1900	June 10, 1900

The International Catalogue of Scientific Literature.—During this week the third biennial conference in connection with the Royal Society's scheme for the publication of an international catalogue of scientific literature has been held at Burlington House. Delegates were present from the United Kingdom, Cape Colony, Natal, India, New South Wales, New Zealand, Queensland, Canada, United States of America, France, Germany, Italy, Japan, Switzerland, Austria, Holland, Belgium, Denmark, Greece, Hungary, Norway, Sweden, and Mexico.

Obituary.—We regret to announce the death of Dr. Julius Althaus, which occurred on Monday last. Dr. Althaus was one of those physicians who devoted considerable attention to electrical treatment, and even if we have been unable at all times to express ourselves at one with him on some of his theories, there is no doubt that he has done much useful work towards advancing the science of electro-therapeutics. Dr. Althaus was a well-known writer on medical subjects, and one of his most recent works was a book on "The Value of Electrical Treatment," which was recently reviewed in our columns. Dr. Althaus, who died at the age of 67, will be regretted not only in medical but also in scientific circles.

Wireless Telegraphy.—It is announced that arrangements are being made at Ilfracombe for experimenting with wireless telegraphy between that town and the Mumbles, across the Bristol Channel, a distance of about 21 miles. The pole to be used is about 120ft. in height. The experiments will extend over a period of about a fortnight.—The *Cape Town Argus* states that wireless telegraphic communication was maintained between the convoy "Doris" and Delagoa Bay while that ship was at Kosi River. This is the only report of wireless telegraphic operations in South Africa that has been received for some time. It would be interesting to know what is at present the occupation of those members of the staff of Marconi's Wireless Telegraph Co. who volunteered to accompany their instruments to the front.

High-Voltage Incandescent Lamps.—An article in a recent issue of the *Electrical World* of New York contains an account of experiments which have been made in the construction of a 500-volt incandescent lamp, of ordinary candle-power. Such a lamp cannot, it is stated, be made with a carbon filament, on account of the comparatively high conductivity of incandescent carbon. The writers tried, with success, mixtures of iridium and nitrates of the rare earths, with solutions of which they impregnated a cotton thread, which was then dried and burned over a Bunsen flame. A current about twice as great as that which it would be required to maintain was next passed through, in order to burn out the last traces of carbon. In another process, one thread was soaked in a solution of some iridium salt, and a second thread in a nitrate of one of the rare earths; these were twisted together, and burned as before. Filaments made by the latter process were not, however, found suitable for voltages above 200. It is finally suggested that the practical refractoriness and the high resistance of these filaments will render them useful as an auxiliary heater in the Nernst lamp.

Thunderstorms.—The reports to hand of the damage done by the thunderstorms during the first half of the present week, show that this visitation was most serious and widespread. The number of fatalities has been larger than usual, and the damage to property has been great. We can but refer to a few of the accidents. Most remarkable of the fatalities is the one by which Major Heywood-Jones lost his life while crossing the camp fields at Harrogate. An umbrella which he was carrying in his hand at the time was destroyed, and his body was marked with severe burns in five or six places. At Sheffield a woman was killed, and in a small village in Co. Kerry two women were killed and a number of others rendered insensible. At Sunderland a man was blinded by the lightning, and has not yet quite recovered. In addition to these accidents to person there have also been some remarkable accidents to buildings, &c. On Tuesday afternoon the chimney-stack of the Peterborough Corporation Electric Light Works was struck, and a heavy derrick was thrown to the ground. This was, fortunately, unaccompanied by any fatality. Church steeples at Little Staughton in Bedfordshire, at Kirkby Stephen, and elsewhere, have not been spared, and in the first case the steeple was entirely destroyed, the masonry breaking through the roof into the basement, and doing considerable damage. Perhaps the most remarkable accident was the total destruction of a group of 14 out of 25 thatched cottages constituting a small hamlet in Northamptonshire.

Society of Engineers.—At a meeting of this society last Monday, a Paper was read on "Electric Traction" by Mr. A. H. Binyon. The author first compared the London traffic with that of New York, and gave figures of its distribution by various channels. He stated that the underground railways in London took only 19 per cent. of the total traffic against 81 per cent. conveyed by omnibuses and tramways. While each of the 5½ millions of people in London travelled 124 times in a year, the New York population of 3½ millions travelled 210 times yearly. He favoured the overhead trolley system as most efficient and economical, and he advocated the side trolley to obviate the unsightliness of very long brackets. The author expressed the opinion that the London United and the London County Council tramways would in time force railway companies to adopt electric traction, even for suburban traffic within a radius of from 10 to 25 miles round London. Beyond this limit he thought that the steam locomotive would beat its electric rival. In combining lighting and tramway plant, Mr. Binyon advocated completely separate dynamos and mains, and favoured slow-speed Corliss engines directly coupled to dynamos of large capacity. He described the double-current generators which would take the load on the alternating or continuous current, according as the demand was far from or near to the station. The power consumption of cars weighing about 12 tons, with speeds of from 6 to 12 miles, and with stops of from 8 to 10 seconds, was given by the author in the following table:—

Power at Trolley Wheel in Board of Trade Units.

Miles per hour.	No. of stops per mile.	B.O.T. units per car.
6	6 to 14	0·7 to 1·08
7	6 „ 13	0·65 „ 1·43
8	5 „ 11	0·75 „ 1·75
9	4 „ 9	0·73 „ 2
10	4 „ 8	0·82 „ 2·2
11	4 „ 7	0·78 „ 2·04
12	3 „ 6	0·73 „ 2·04

The use of meters in cars was recommended for the reason that from 30 to 40 per cent. in power of the waste caused by the careless handling of controllers could be saved.

MEETINGS OF SCIENTIFIC AND ENGINEERING SOCIETIES, &c.

WEDNESDAY, June 20th.

ROYAL METEOROLOGICAL SOCIETY.

4.30 p.m. Ordinary Meeting at 70, Victoria-street, Westminster, S.W.

ROYAL MICROSCOPICAL SOCIETY.

8 p.m. Ordinary Meeting at 20, Hanover-square, W.

FRIDAY, June 22nd.

PHYSICAL SOCIETY.

5 p.m. Meeting in the Rooms of the Chemical Society, Burlington House. The following Papers will be read: (1) "Notes on Gas Thermometry," by Dr. P. Chappius; (2) "A Comparison of Impure Platinum Thermometers," by H. M. Tory; (3) "On the Law of Cailletet and Mathias and the Critical Density," by Prof. J. Young, F.R.S.

THE CENTRAL LONDON RAILWAY.

(*Continued from page 212.*)

PART I.—POWER GENERATION AND DISTRIBUTION.

The Power Station.—The power station is situated on an extensive 20-acre tract of land at Shepherd's Bush, used partly for the necessary buildings and sheds, and partly as a shunting and train-make-up yard. A plan of this area is shown in Fig. 5. The power station is an ample and substantial structure in red brick, with two lofty chimney stacks in the same material. Figs. 6 and 7 show the general construction of this building. The boiler house (Fig. 8) is 148ft. long by 87ft. wide, and it accommodates at present 16 Babcock-Wilcox boilers arranged in two rows with a central gangway. Each boiler is rated at 12,000lb. of steam per hour at 160lb. pressure, with hot feed from the Green's economisers. Vicars' mechanical stokers are fitted to the furnaces, and the arrangements for the conveyance of fuel from the railway trucks to the furnaces are elaborate and complete. The mechanical conveyer erected by Messrs. C. W. Hunt and Co. consists of 200 buckets, each having a maximum capacity of 140lb., and a normal load of 1 cwt. The normal speed of the conveyer is 40ft. per minute. Of the total 200 buckets only 20 are at any one time being actually lifted, the others moving either along the top of the boilers at a height of 25ft. from the floor, or descending at the far end and returning underneath the boiler gangway. The conveyer is driven by an 8 H.P. continuous-current motor, taking from 10 to 12 amperes at 500 volts. It will be seen that the conveyer arrangements allow of 150 tons of coal being transported to the bunkers every hour. As the total capacity of the bunkers is 1,000 tons, they can be filled in about seven hours. This constitutes a sufficient supply for over a week. The coal descends by gravity from the bunkers through shoots to the mechanical stoker hoppers, which are regulated by a hand valve. These are shown in Fig. 8. The stokers are driven by two Bumsted and Chandler vertical steam engines, either or both of which may be used. In the boiler flues are placed four Green's economisers, for which two separate rooms have been erected. Each economiser consists of 768 tubes, with the usual scraping gear, &c. After passing through the economisers, the furnace gases ascend the two chimneys, being discharged at a height of 250ft. above the ground level. These chimneys are 10ft. internal diameter at the base. The economiser scrapers are driven by continuous-current motors, a 5 H.P. motor being provided for each pair of economisers.

Steam passes from each boiler through an 8in. stand pipe to the main steam range, each engine being also supplied from the main range by a pipe of the same diameter. The main steam pipes are carried over the boiler tops and underneath the machinery-room floor. The exhaust pipes and the injection and discharge pipes are similarly placed below the machinery-room floor, the injection pipe being 20in. in diameter, and the discharge pipe 22in. in diameter. As shown in Fig. 10 each engine is provided with its independent condenser.

The machinery room is 200ft. long by 88ft. wide, and is 60ft. in height. There are at present erected the following steam-

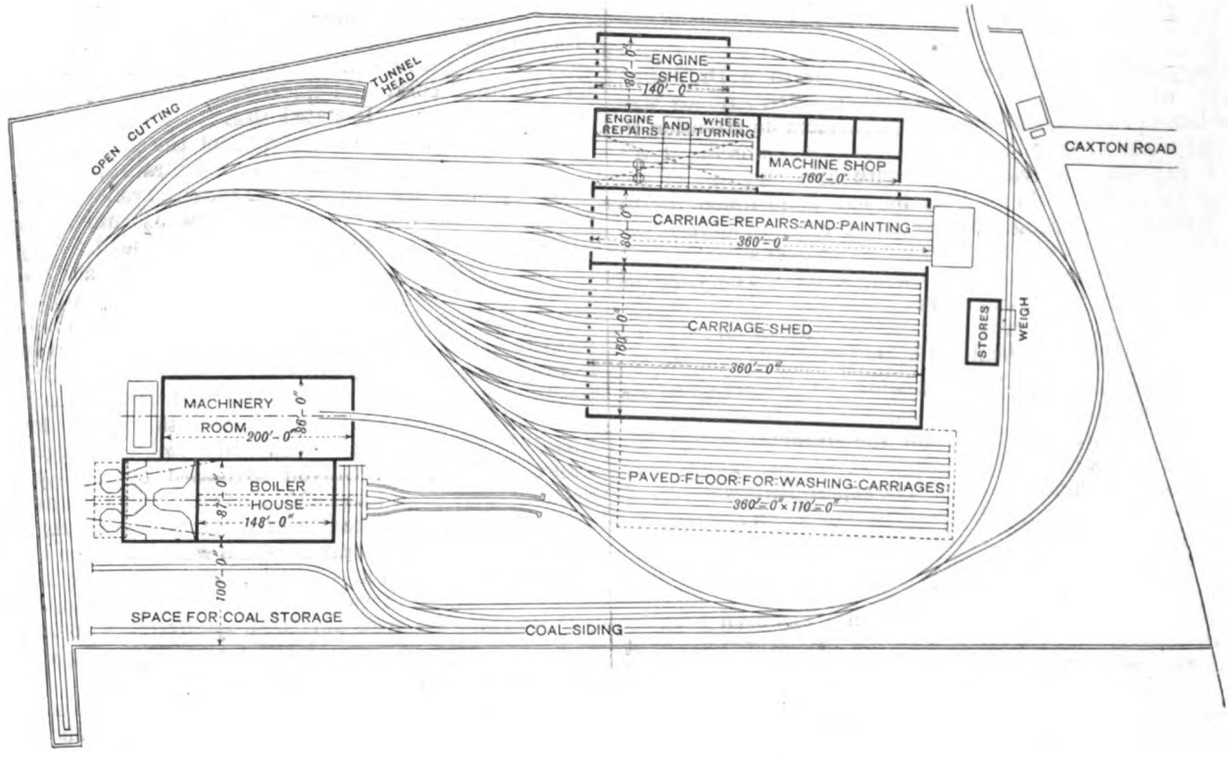

FIG. 5.—PLAN OF DEPÔT AT SHEPHERD'S BUSH.

driven sets: Six main steam generating sets, four continuous-current exciter sets, and two continuous-current lighting sets. All the sets are direct-coupled. The main generating sets consist of 850 kw. three-phase generators, running at 94 revs. per min. and developing 5,000 volts, direct-coupled to horizontal cross-compound Allis steam engines, as shown in Fig. 9. The engines are fitted with Reynolds's Corliss valve gear, and were built by the E. P. Allis Co., of Milwaukee, U.S.A. The high-pressure cylinders are 24in. diameter, and the low-pressure cylinders 46in. in diameter, each piston having a 4ft. stroke. Governing is effected on the cut-off of each cylinder, and there is, in addition, a safety steam device so arranged that on the failure of the ordinary governors, the racing of the engine will cause steam to be shut off. The main shaft is of hammered iron 20in. in diameter at the bearings and 22in. diameter at the centre, running in Babbitt metal bearings 3ft. in length. This shaft carries a 50-ton flywheel, built in eight sections, and the magnet wheel of the three-phase generators. These generators are of the revolving field type and at the normal speed of 94 revs. per min. generate three-phase current at 25 cycles per second. The

Digitized by Google

revolving field consists of 32 outwardly projecting laminated poles and magnet cores, bolted to a cast-steel ring. This ring is carried by a heavy cast-iron spider, which in turn is mounted on the extended engine shaft (situated between the high and low pressure cranks) and keyed firmly thereto. The field coils are wound on formers, being afterwards slipped on to the magnet cores and insulated therefrom. They have protecting flanges of wood, and each coil consists of 79½ turns of copper strip, 1·6in. by 0·08in., wound on edge. The object of the half turn per coil is that the terminals of each completed coil shall be on opposite sides of the spool, and when in position, the adjacent terminals being joined together, this connects up the whole winding in series in the best possible manner, both mechanically and electrically. The exciter voltage is 125, and for the normal full load at 5,000 volts terminal pressure with unity power factor, an excitation of 110 amperes is required. The diameter of the field is 143·375in. and the length of each pole arc 9in., while the laminations are piled to a depth of 14½in., making the total area of each pole face 130 sq. in. The collectors, which merely consist of two rings to take the exciting current, are each furnished with two copper gauze brushes, and are supported on the engine shaft alongside the field spider, being insulated therefrom by ebonite. The entire weight of the revolving field, with spider, is approximately 34,000lb. The armature core, which is built up of separately insulated sheet steel punchings 0·014in. thick, is supported by a cast-iron frame into which the laminæ are dovetailed. The actual or active length of the iron (parallel to the shaft) is 10·8in., and there are five ventilating ducts, each ⅜in. wide, spaced at

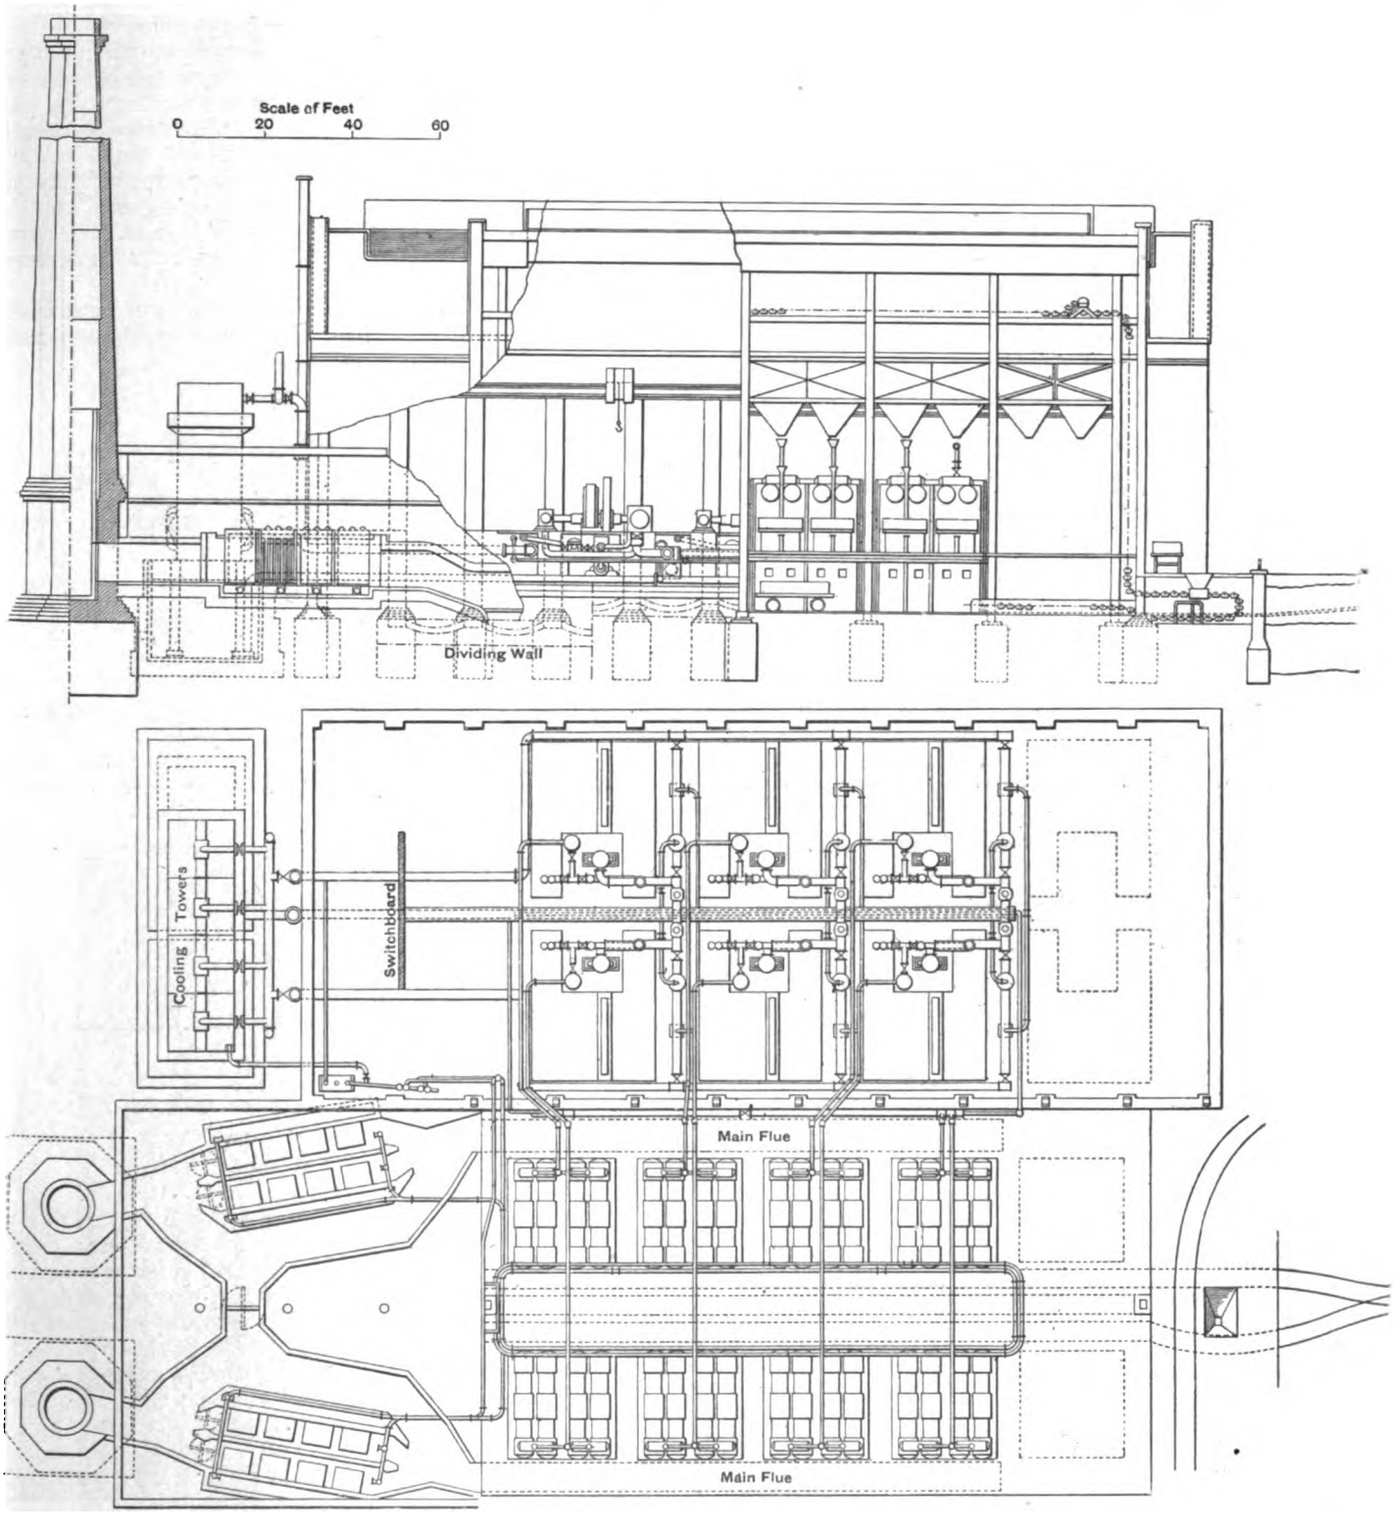

FIG. 6.—LONGITUDINAL SECTION AND PLAN OF POWER STATION.

Digitized by Google

equal distances apart, which, with the space taken up by the insulation between the punchings, makes the total length of the armature iron (along the shaft) 14½in. The internal diameter of the armature is 144in., thus leaving an air gap of

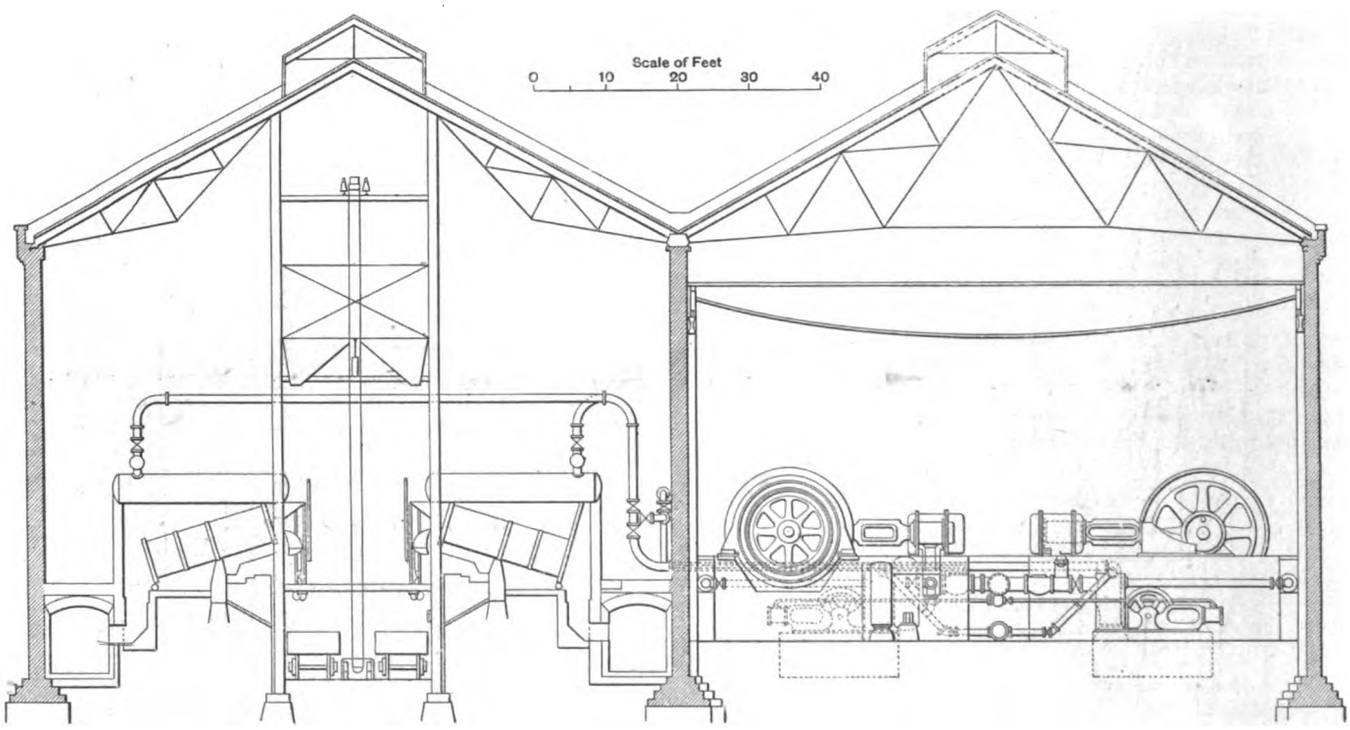

FIG. 7.—TRANSVERSE SECTION OF POWER STATION.

0·3125in. The armature is of the slotted or iron-clad type of construction; the slots, which, of course, are on the inner diameter of the armature, and of which there are 192, are 3·625in. deep by 1·313in. wide. The winding consists

pole. This distribution of winding lessens the inductance, and consequently the reactance of the armature, and improves the thermal properties by distributing one of the chief sources of heating—namely, the C^2R losses—over a larger

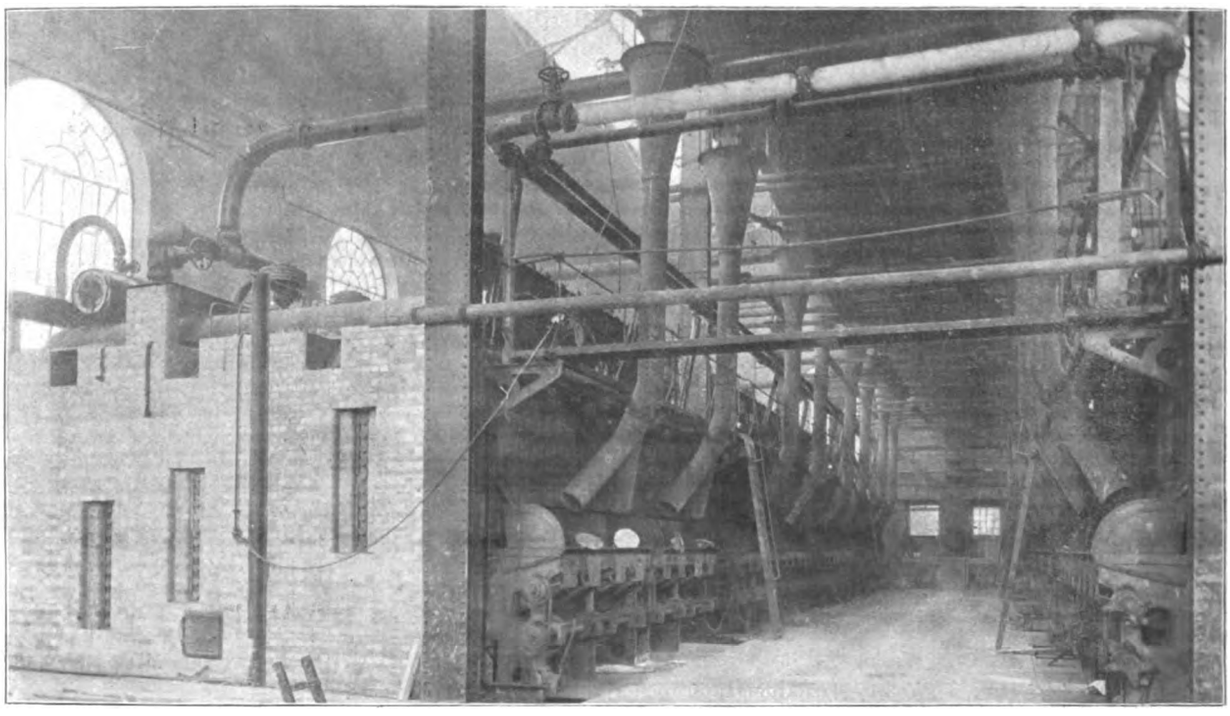

FIG. 8.—VIEW OF BOILER RANGES.

of coils wound on formers, and each separately insulated so as to allow of being readily removed in case of repairs. Each coil has 14 turns of a conductor made up of 36 strands, 17 B.W.G. There are 96 such coils

dissipating area and closer to the radiating surface than is the case if the winding, and consequently the C^2R losses, be concentrated in one deep slot per pole piece. The coils are held in place in the slots by means of wooden wedges driven

Digitized by Google

longitudinally into dovetail grooves at the top of the slots, while the projecting ends of the coils are mechanically protected by means of gunmetal shields. The armatures have been tested at a pressure of 10,000 volts alternating. The armature punchings weigh about 4,500lb., while the complete armature, with its supporting frame, weighs approximately 48,600lb.

Beneath each main set the condensing plant is erected as shown in Fig. 10. This condensing plant is of the Allis jet type. Each condenser can deal with 26,000lb of steam per hour normally, or 30,000lb. if required. The pumps are double-acting, 28in. diameter and 24in. stroke, and they can draw water through a 22in. wrought-iron pipe running down the centre of the basement, from the hot-well situated

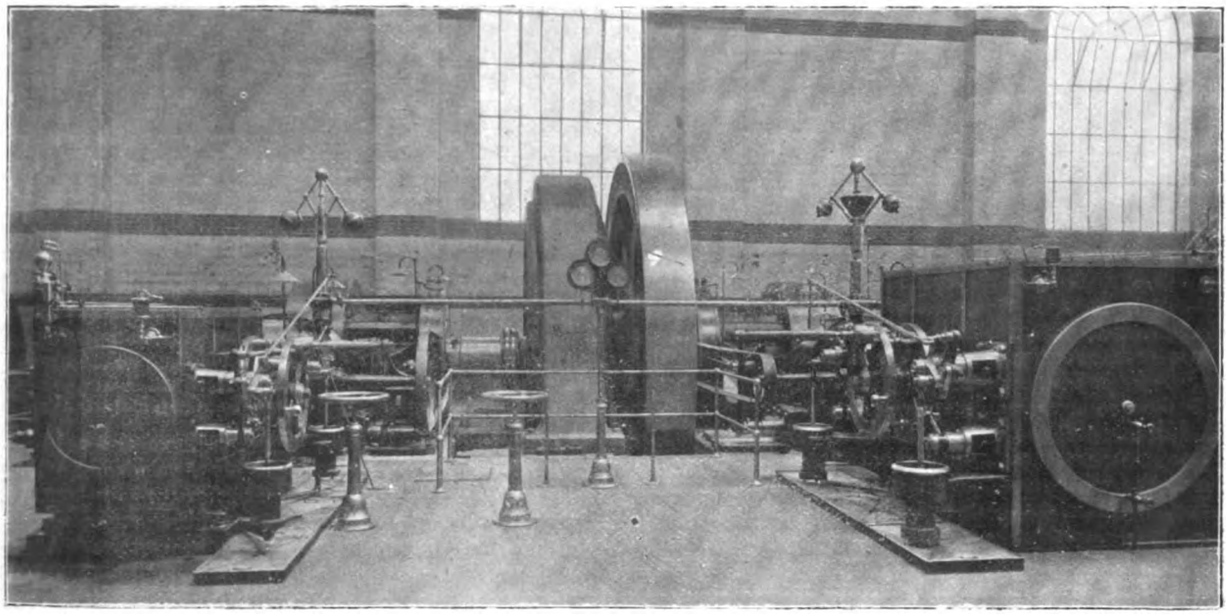

FIG. 9.—MAIN GENERATING SET. VIEW FROM CYLINDER ENDS.

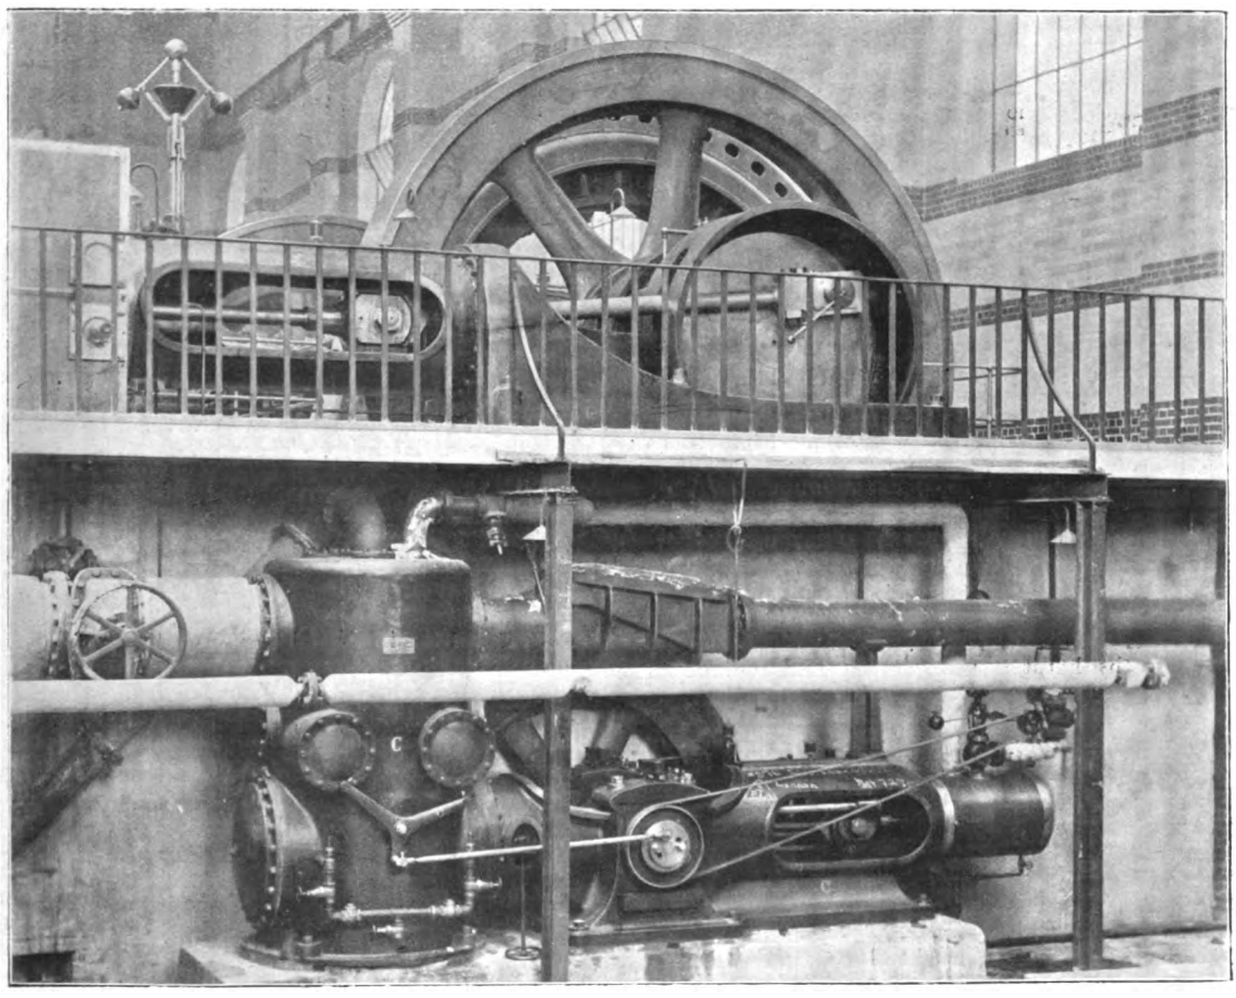

FIG. 10.—MAIN GENERATING SET, SHOWING CONDENSER.

beneath the cooling towers at the north end of the building, and deliver it back through two 18in. pipes, laid one at each end of the basement, to the top of the Barnard cooling towers. The exhaust steam from the condenser engines passes into the receiver of the main engines so as to secure the economy of compounding. An automatic release valve is provided for each engine, so that should the vacuum fail it exhausts to atmosphere. There is an auxiliary condensing plant, which takes the steam from the exciter and lighting sets, and also from the auxiliary plant. This consists of a Wheeler surface condenser of 1,900 sq. ft. cooling surface. The circulating water is drawn from the hot-well beneath the cooling towers, and delivered back to the top of the cooling towers, while the air pump discharges directly into the hot-well.

CONTEMPORARY ELECTRICAL SCIENCE.

[Compiled by E. E. FOURNIER D'ALBE.]

Active Principle of Uranium.—Sir W. Crookes has succeeded in isolating the radio-active principle of uranium, after a long series of tests and reactions made with all sorts of uranium minerals and all sorts of methods. Ammonium carbonate was eventually found capable of separating out the uranium and leaving the unknown active substance, provisionally denoted by the symbol UrX by its discoverer. By analogy with gallium, scandium, and polonium, the new substance might as well be called anglium or britannium as anything else. The facts known about it are not sufficient so far to warrant its final christening. It is about 300 times more active than uranium. It may be separated from polonium by sulphuretted hydrogen in an acid solution, which precipitates the latter but not the former. But no definite proof has yet been brought that it is not identical with radium. The spectroscopic test fails owing to its lack of sensitiveness in comparison with the photographic test! A further difficulty is introduced by the fact that precipitates have a tendency to drag down with them other substances which should remain in the filtrate. But the required proofs will doubtless soon be forthcoming.

[Sir W. CROOKES, *Royal Society*, Paper read May 10, 1900.]

Röntgen Rays produced by a Continuous Current.—J. Trowbridge has lately completed the installation of a plant of 20,000 storoge cells in the Jefferson Physical Laboratory. This places at his disposal an E.M.F. of over 40,000 volts, and a comparatively steady current through a large resistance. He has succeeded in obtaining X-rays of exceptional brilliancy with the aid of this high E.M.F., which, moreover, yield negatives of great contrast, showing traces of the shadows of ligaments and muscles. The great advantage of this new method of generating the rays is the possibility of exactly regulating the current and difference of potential which is necessary to excite the rays. This is not possible by any of the other methods hitherto used. When the X-ray tube is first connected to the battery terminals no current flows; it is necessary to heat the tube with a bunsen burner. At a certain critical temperature the tube suddenly lights up with a vivid fluorescence, and the rays are then given off with great intensity. The author employed a distilled-water resistance of about 4,000,000 ohms. This places it beyond a doubt that no electrical oscillations had any part in the production of the X-rays.

[J. TROWBRIDGE, *Am. J. Science*, June, 1900.]

Resistance of Metallic Films.—More than 20 years ago Wright pointed out a method of producing thin metallic films upon glass by cathode ray deposition. These films had very brilliant reflecting surfaces, and showed characteristic colours by transmitted light. A. C. Longden has studied the films with special reference to their electrical resistance. He found very soon that the thinnest films have an enormously high electric resistance, very much higher than is warranted by their thickness. A valuable discovery was that the sign of the temperature coefficient of the resistance is variable with the thickness. The thinnest films have, like liquids, a negative temperature coefficient. At a certain thickness the temperature coefficient becomes zero, and the film does not change in resistance with the temperature. A further stability may be imparted by artificial ageing in a bath of hot oil, and subsequent protection from the atmosphere, either by enclosing in a vacuum or embedding in paraffin or in rubber varnish. Contacts are made by thick electro-deposition. The final product is a very accurate standard of from a few ohms to several megohms, which will never vary by more than a few hundredths of 1 per cent.

[A. C. LONGDEN, *Am. J. Science*, June, 1900.]

Influence of Gravitation upon Resistance.—A somewhat recondite but none the less interesting research has been carried out by G. Gore. He had already shown that the presence of a mass of a heavy substance near one of the electrodes of a voltaic cell alters its E.M.F. Why it should do so could not be determined except by a lengthy series of experiments upon solids and electrolytes. The most obvious explanation was some change in the constitution of the electrode. If there were any such change, it might also show itself in a change of resistance consequent upon embedding a coil in a block of lead. A somewhat tedious series of experiments has been carried out by the author, and it says a good deal for his care and accuracy that he should have obtained a negative result. For positive results, due to secondary causes, are very much more easy to obtain. It appears, therefore, that the gravitational action observed in the case of electrolytic cells probably does not act through the metal. A full explanation of this interesting effect will probably demand more than the patience of a single worker.

[G. Gore, *Phil. Mag.*, June, 1900.]

Interception of Wireless Telegrams.—No system of limiting the receipt of wireless messages has as yet been described, though the solution of the problem has already been several times announced. D. Tommasi suggests a plan which appears feasible enough, though it only reduces the space within which a given message can be received to a spherical shell instead of a line or a point. The idea is to use two transmitters of different ranges of action. The transmitter with the larger range is used for sending the message to the station for which it is intended, while the transmitter with the shorter range is employed in confusing the message within that range by an unmeaning series of dots and dashes. The range of a transmitter can fortunately be adjusted by altering the size of the spark-gap, and thus it should not be difficult to restrict the chances of interception to a zone of, say, half-a-mile. If, in addition, the spherical wave-train could, by reflection or otherwise, be converted into a beam of the form of a searchlight, the problem would be solved in a way. But, of course, a very much more satisfactory solution would be a device of the lock-and-key kind, in which messages could only be received by an instrument of very special construction and dimensions.

[D. Tommasi, *Comptes Rendus*, May 14, 1900.]

Magnetised Coherers.—The coherers with magnetic electrodes devised by C. Tissot (see *The Electrician*, May 4, p. 41) have been applied with great success to the exchange of wireless messages between French battleships and the Portzic lighthouse. The most interesting feature of the contrivance is that it does not contain any of the devices patented by Marconi. The height of the masts did not exceed 100ft., and good signals were obtained at a distance of 33 miles. The coil employed for transmission was a transformer by Wydts and Rochefort. The messages exhanged were complete phrases, telegraphed by the ordinary Morse code and read by the ordinary ship telegraphists on board. The filings in the coherer and the iron terminals are kept very dry, and are best enclosed in a tube hermetically sealed and containing a few fragments of calcium carbide. The E.M.F. of the circuit may be varied within wide limits without interfering with the clearness of the signals. The ordinary resistance of the coherer is from 200,000 to 500,000 ohms. At coherence, it falls to something between 1,500 and 3,000 ohms. The fall of resistance in magnetised coherers is not entirely due to the impact of the waves. The increase of current strength itself brings about a further fall.

[C. Tissot, *Comptes Rendus*, May 21, 1900.]

Electric Pendulum.—An electrically-driven pendulum should, according to Lippmann, fulfil the following conditions: The restitution of kinetic energy should take place when the energy is all kinetic—*i.e.*, when the pendulum passes through the vertical; the "electric sticking" should be abolished—*i.e.*, the adhesion between two points at which the circuit is broken; the isochronism of the pendulum must not be disturbed by the electric contact; and the quantity of energy imparted at every oscillation must be constant, and independent of the state of the battery. Most of these conditions are fulfilled by a pendulum designed by C. Fery. A permanent horseshoe magnet is attached to the bob of the pendulum, and one arm of it passes at every swing into a coil through which a constant quantity of electricity is sent just at the moment at which the pendulum is passing through the vertical. The manner in which the constant quantity of electricity is obtained from a possibly inconstant battery is very ingenious. A balancing arm bears at its ends two coils which fill up the spaces between the poles of two horseshoe magnets. The arm is of soft iron, and when a current traverses either of the coils it is temporarily magnetised. One of the coils is the "motor" coil, and receives the current from the battery. It is attracted by the electromagnet against the force of a spring, and thus brings about a definite displacement of the other coil in its magnetic field. The induced current caused by this displacement traverses the coil which receives the magnet attached to the bob, and thus gives to the latter the impulse required. With an E.M.F. of 10 volts, the current required is only of the order of a milliampere, and the amount of zinc consumed in a whole year would not exceed 20 grammes. Even so, however, the "efficiency" of the apparatus is very small, considering that the power required is only a forty-millionth of a horse-power.

[C. Fery, *Comptes Rendus*, May 7, 1900.]

ON THE SPARK DUE TO THE BREAK OF AN ELECTRIC CIRCUIT.

BY K. B. JOHNSON.

Circuits in general being of very different nature we will imagine an ideal one which can easily be realised approximately, and from this imaginary circuit we will also deduce the true expression of the extra current of the break. We will suppose the circuit to be composed of a single coil and a battery, beside which there is a make-and-break apparatus. The terminals of a condenser are fastened on either side of the interruptor.

Let L be the coefficient of self-induction of the circuit, *i.e.*, that of the coil; R the resistance of the circuit; and C the capacity of the circuit, *i.e.*, that of the condenser increased a little owing to the capacity of the coil and the battery. Further, let E_0 be the electromotive force of the battery, E the potential difference of the condenser at time t, and I the strength of the current at time t from the break of the circuit. Then, for determining the extra current we have the well-known formulæ:

$$L\frac{dI}{dt} + RI = -E, \quad \ldots\ldots \quad (1)$$

and

$$I = C\frac{dE}{dt}, \quad \ldots\ldots \quad (2)$$

as is given by Mr. L. Robb in a Paper "On Oscillations that occur in the Charging of a Condenser" (*Phil. Mag.*, Ser. V., Vol. XXXIV., p. 389, 1892).

Integrating the above equations, we have

$$E = A\epsilon^{-\alpha t}\sin(\beta t + B), \quad \ldots\ldots \quad (3)$$

and

$$T = AC\epsilon^{-\alpha t}[-\alpha\sin(\beta t + B) + \beta\cos(\beta t + B)], \quad (4)$$

the values of α and β being as follows:—

$$\alpha = \frac{R}{2L}, \quad \text{and } \beta = \frac{\sqrt{1 - CR^2/4L}}{\sqrt{LC}}. \quad \ldots\ldots \quad (5)$$

A and B are arbitrary constants to be determined by the initial conditions—viz., that at the time of break, or when $t = 0$, the potential difference of the condenser, is zero, and the strength of current is that of the steady current $\frac{E_0}{R}$. Thus, it becomes $B = 0$ and $A = \frac{E_0}{CR\beta}$. Substituting these values in (4) and (5), we have

$$E = \frac{E_0}{CR\beta}\epsilon^{-\alpha t}\sin\beta t, \quad \ldots\ldots \quad (6)$$

and

$$I = \frac{E_0}{R}\epsilon^{-\alpha t}\left[\cos\beta t - \frac{\alpha}{\beta}\sin\beta t\right]. \quad \ldots \quad (7)$$

It may be observed that we assume that the spark is entirely suppressed. This condition being satisfied, the above

Digitized by Google

formulæ (6) and (7) give the analytical expressions of potential difference and strength of current. Hence, it follows that the potential difference at time

$$t=\frac{1}{\beta}\tan^{-1}\left(\frac{\beta}{\alpha}\right)$$

attains a maximum value.

$$E_m=\frac{E_0}{CR\beta}\cdot\epsilon^{-\frac{\alpha}{\beta}\tan^{-1}\left(\frac{\beta}{\alpha}\right)}=\frac{E_0}{R}\cdot\frac{\sqrt{\frac{L}{C}}}{\sqrt{1-\frac{CR^2}{4L}}}\cdot\epsilon^{-\frac{\alpha}{\beta}\tan^{-1}\left(\frac{\beta}{\alpha}\right)} \quad (8)$$

Evidently the spark at the break is generally caused by the increasing potential difference of the terminals, or, what is the same, that of the condenser. Hence, if the potential difference never rises to so large an amount as is required to overcome the "surface resistance" in the interruptor, no spark will take place at the break. Therefore it depends only on the value of E_m in (8) whether a spark will or will not pass, whence the formula (8) may be discussed. There β is always positive, and may be varied from 0 to $+\infty$ by varying C and R. When β increases from 0 to $+\infty$ the multiplier $\epsilon^{-\frac{\alpha}{\beta}\tan^{-1}\left(\frac{\beta}{\alpha}\right)}$ only increases from $1/\epsilon$ to 1, and therefore the multiplier has very little influence on the variation of E_m. Then it follows from (8) that, by making the capacity C or the resistance R large enough, it is always possible to diminish the value of E_m enough for suppressing the spark. However, it may be observed that, the capacity of a microfarad being only 10^{-15} in absolute measure, there would generally be required so large a capacity for suppressing the spark that the use of such a method never occurs in practice. The general practical rules for suppressing the spark are according to the formula (8)—viz., to increase either the resistance alone or both the resistance and the capacity before the break.

The spark not being suppressed, it is obvious that the preceding formula (6) ceases to be an expression for the potential difference when the spark enters, but there is no reason why it should not express the potential difference from the break to the passing spark.

Hitherto we have supposed a circuit of a certain form—viz, such that the capacity is situated at the terminals of the broken circuit; but it can easily be proved that the behaviour of the extra current will be similar to this in other cases also. At first let the condenser be taken away from the imaginary circuit, then C may denote the capacity of the coil and battery, and, according to the opinion of Von Helmholtz, the capacity of a coil may be considered as situated in the terminals. Thus, the formulæ (6) and (7) may be applied also to this case, and from (6) it follows that, β being a very small quantity, E will generally be very large, and thus a spark will pass, unless $\frac{E_0}{R}$ be very small.

That the foregoing case of breaking a circuit in general may probably not essentially disagree with the conditions represented by the above formulæ may be tested by considering another ideal case, which is so different from that considered at first that almost every practical case can be regarded as situated between the two limits—viz., between the first imaginary circuit and the one we are now going to consider. Suppose that the capacity is uniformly extended along the wire forming the circuit, so that the capacity per unit of length is the same at every point of the circuit; and also that the resistance and the self-induction are equal per unit of length, which may be approximately true for a submarine cable. This case has been already considered by Mr. O. Heaviside in a Paper "On the Extra Current" (*Phil. Mag.*, Ser. V., Vol. II., p. 135, 1876), and in formula (20), p. 141, he there gives an expression for the potential v at any point at the distance x from one end of the circuit. Introducing the coefficients L, C, and R for the whole length of the circuit instead of the quantities *sl*, *cl*, and *kl*, used in the above-mentioned formula (20) of Heaviside's, we have

$$v=-\frac{8E_0}{R}\sqrt{\frac{L}{C}}\epsilon^{-\frac{R}{2L}t}\sum_1^\infty i\frac{\cos(2i-1)\frac{\pi x}{L}}{\sqrt{(2i-1)^2\pi^2-\frac{CR^2}{4L}}}\sin t\sqrt{\frac{(2i-1)^2\pi^2}{LC}-\frac{R^2}{4L^2}}$$

v being the potential of the point x at time t from the break.

Putting $\gamma=l$, we have the potential v_1 at one end:

$$v_1=\frac{8E_0}{R}\sqrt{\frac{L}{C}}\epsilon^{-\frac{R}{2L}t}\sum_1^\infty i\frac{\sin t\sqrt{\frac{(2i-1)^2\pi^2}{LC}-\frac{R^2}{4L^2}}}{\sqrt{(2i-1)^2\pi^2-\frac{CR^2}{4L}}} \quad (9)$$

Putting $\gamma=0$, we have the potential of the other end to be $-v_1$, and thus the potential difference of the terminals is $2v_1$, or

$$2v_1=16\frac{E_0}{R}\sqrt{\frac{L}{C}}\epsilon^{-\frac{R}{2L}t}\sum_1^\infty i\frac{\sin t\sqrt{\frac{(2i-1)^2\pi^2}{LC}-\frac{R^2}{4L^2}}}{\sqrt{(2i-1)^2\pi^2-\frac{CR^2}{4L}}} \quad (10)$$

The analogy of the formula (10) with that of (6) is evident; and the reasoning about the formula (6) as to the suppression of the spark may be immediately applied on the formula (10).

Hence, it seems that there is little difference, in considering the spark or its suppression, whether the capacity is situated at the ends of the broken circuit or is uniformly distributed along the whole length of the circuit. As every practical case is an intermediate one between these extremes, it may easily be concluded that the reasoning about a circuit with the capacity at its terminals may be true for a circuit in general to a sufficiently close degree of approximation.

CURRENT-RUSHES INTO TRANSFORMERS.

BY R. C. CLINKER.

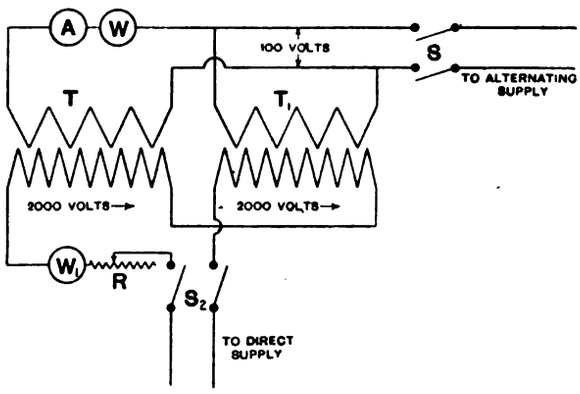
It is a well-known fact that at the instant of switching a transformer or a group of transformers on to a live circuit, a momentary rush of current often takes place through the primary winding. This manifests itself usually by a kick of the ammeter, if one happens to be in circuit, or by a loud hum which dies away to the normal sound within the first few seconds. The explanation of the effect is probably this:—The magnetic condition of the iron before the transformer is switched on depends upon that point in the cycle at which the switch was last opened. The magnetic circuit being a closed one, the iron has no poles which tend to demagnetise, hence the induction in the core may have a maximum, zero, or intermediate value, depending upon the instantaneous value of the magnetising current when the voltage was removed from its terminals. If now voltage be suddenly re-applied to the primary in such a direction that to produce the necessary back E.M.F. a change of induction is required in the direction in which the iron is already highly magnetised, the permeability of the iron is so low in this direction that a large rush of current is necessary to produce the required change of flux. During the next few seconds the magnetic cycle in the iron does not take place around the zero point. Indeed, the direction of magnetisation may not even reverse in sign during the first few cycles. The tendency which exists in the iron, however, towards zero magnetisation asserts itself, and the magnetic cycle slowly descends from higher values of induction until it takes place around the zero point. One or two interesting experiments which the author made on this point some months ago make this action more apparent. In one, a direct-current ammeter with well-damped needle (such as a Weston instrument) is included in the circuit when switching on. If this ammeter be of fairly small range, a *direct* current will be seen to pass through the transformer for a considerable time after the circuit is closed. Thus, in the author's test, a 10 kw. transformer was experimented upon, a 5 ampere Weston ammeter being placed in circuit with the 100 volt terminals, which could be switched on to a 100 cycle supply. The normal alternating no-load current was about 1·5 amperes, but a kick of fully 5 amperes could often be obtained upon the Weston ammeter, the direction being of course either positive or negative. After the first kick the needle slowly sank to zero, but in some cases a small direct current flowed

Digitized by Google

through the transformer for fully one minute after the closing of the switch. It is evident that this direct current means a continuous change of the total induction linked with the circuit, going on quite independently of the cycle or range of induction-value necessary to supply the back E.M.F.

The effect may be produced more artificially by magnetising the core in one direction with a direct current, while the alternating voltage is still applied to the terminals. To neutralise the induced voltage in the magnetising coil, the author used two transformers connected as in the diagram. T and T_1 were two 50 kw. transformers, both of 20:1 ratio. Their low pressure windings were paralleled and connected to a 100 volt source of alternating supply, two ammeters, one an alternating-current instrument (A) and the other a direct-current Weston (W) being included in the circuit. The high pressure windings were connected so that their E.M.F.'s opposed, and a direct-current circuit with resistance and ammeter (W_1) was introduced in series with them. A direct current could thus be made to flow in both primaries quite independently of any induced voltage.

On closing switch S_1 the ammeter A read, of course, the no-load current of T, while no permanent deflection was produced on W, the pointer merely vibrating over the zero. As A was a 60-ampere instrument, this small current produced very little deflection. On closing S_2 and allowing current to flow through the high-pressure coils, a momentary direct current was, of course, indicated by W, while the no-load current read on A was increased, owing to the lower



average permeability of the iron at the higher inductions through which the magnetic cycle was taking place. By reducing R sufficiently, this no-load current could be increased to 60 amperes, the scale limit of ammeter A. The interesting point of the experiment, however, lay in the effect of suddenly opening switch S_2. The magnetic cycle, having no resultant magnetising force left to support it at so high an induction, gradually descended to its normal position, occupying in its descent an interval of at least one minute. For that space of time a direct current could be observed flowing through W. The immediate effect of opening S_2 upon the reading of A was to reduce it about one-third, from which value it slowly crept down to the normal magnetising current. One effect of working at this high induction was to cause the transformers to hum loudly.

The method of connection used in this experiment may also be used to show that the hysteresis loss in the cores is dependent only upon the total range through which the induction passes, and not upon the actual value of that induction, a wattmeter being placed in circuit to measure this in the usual way.

A FRICTIONLESS MOTOR METER.*

BY S. EVERSHED.

Preliminary.—Lest their should be any misapprehension of the title of this Paper, let it be said at once that the adjective is used in the comparative sense already sanctioned by such analogous phrases as "smokeless powder," "watertight compartment," and so on. Every one knows that smokeless powder makes some smoke and that a watertight compartment usually leaks, but the smoke is not sufficient to enable the position of a gun to be seen nor to interfere with other military operations, and the leaks are not sufficient to sink the ship. Similarly a frictionless meter is one in which the friction commonly met with has been so greatly reduced as to render correction unnecessary, and reduce wear and tear to an inappreciable amount.

In the course of the last few years the author has tested some of the better known types of motor meter in general use, with the result that the lowest observed value for the moment of frictional resistanceis 57 dyne cm. and the highest nearly 1,400 dyne cm., while values of from 300 to 500 dyne cm. are quite usual. All these tests were carried out upon new meters which had been carefully adjusted by the makers. In the author's meter the frictionmoments so far observed vary from 1·5 dyne cm. in a new meter up to 3·5 dyne cm. in one which has run for many million revolutions. These figures will, it is hoped, serve to excuse if not to justify the title "frictionless."

Among the many links in the long chain connecting the energy locked in the coal store of an electric power station with the work done on the consumers' premises the supply meter is by no means the least important. Yet is has perhaps received less attention from the Institution of Electrical Engineers than any other essential part of an electric supply. It is difficult to assign any cause for this apparent neglect: electric meters began to be invented in the earliest days of electric lighting, and by the time the industry was on a sound basis there were already a large number, working on a variety of wholly different principles, awaiting the test of practical use. There were motor meters, electrolytic meters, differential clock meters, feeler meters—in addition to a host of nondescript meters. There were many kinds of each of the fundamental types; some of them based on more or less simple laws, others practically lawless and destined on that account to succumb in the struggle for existence. But the extraordinary activity of the meter inventor and the very wide field he was working in has left scarcely a trace in the *Proceedings* of the Institution.† While we have over and over again discussed every other link—coal, boilers, engines, dynamos, mains, batteries, transformers, lamps, and so on—and devoted a vast amount of learning and experience to efficiencies (reckoned to fractions of 1 per cent.), to load factors, to costs (calculated to minute fractions of a penny), we have been content to pass the meter over in silence. Is the average meter, then, so good that it needs no attention from us? Far from it; erratic meters are not unknown. One will allow a consumer to run a lamp all day for nothing; another for 30 or 40 per cent. discount. Precious energy after having its cost ascertained to the hundredth of a penny is positively being given away every day by sticky motor meters, unbalanced clock meters, and the like. As a set-off one hears of meters running up a big bill when the consumer is out of town and the main switch off.

Bearing all this in mind, the author feels that a Paper devoted to the description of an attempt to remove some of the more obvious defects of a particular class of meter—the motor type—together with an exhibition of the outcome of that attempt will need no apology.

Motor Meters.—The fundamental principle of all motor meters is very simple. The driving moment (torque) of the motor is made proportional to the power (or to the current, in a coulomb or electricity meter) being metered, and the speed of the motor is controlled by a brake whose resisting moment is proportional to the speed. Consequently the speed will be proportional to the power (or to the current), and the number of revolutions made in a given time will be proportional to the energy (or to the electricity) supplied. This was first clearly stated by Profs. Ayrton and Perry in describing their well known energy meter, the forerunner of nearly all energy meters since invented.‡ Unfortunately, it is easier to lay down the law than it is to make a meter obey it. A motor axle must have bearings; a current has to be led to the rotating armature either by brushes or by means of a mercury bath; and there is a counting train to be driven. All these things involve friction, and a part, often a very considerable fraction, of the available driving torque

* Paper read before the Institution of Electrical Engineers, May 10.

† Here are the only Papers on meters published from 1885 to 1899:—Mr. Hookham, in demonstrating his meter, 1889, *Journal* of the Institution of Electrical Engineers, Vol. XVIII., p. 688 [*see* also *The Electrician*, Vol. XXIII., p. 124—Ed., *E.*]; Mr. Gibbings, "Registration of Small Currents used for Electric Lighting and other Purposes," *Journal* of the Institution of Electrical Engineers, 1898, Vol. XXVII., p. 547 [*see* also *The Electrician*, Vol. XLI., p. 112—Ed., *E.*].

will be used up to overcome it. There are other minor difficulties, such as the construction of a motor without iron, variation of electrical resistance due to temperature, and so on, but practically friction is the only serious trouble in a motor meter; it limits the accuracy and involves a good deal of wear and tear.

If one attempts to design a practicable energy meter of the type described by Ayrton and Perry, one is hampered by certain fairly definite limitations, such as cost of manufacture, drop in the current coils at full load (or power wasted in them if that is the more important item), and above all waste of power in pressure circuit. If the full-load drop is fixed at one volt, and the wasted power in the pressure circuit is limited to three or four watts, it will be found that the maximum driving torque obtainable (on the assumption that the meter is to be saleable at present average prices) is something like 20,000 dyne cm., and the friction may be from 300 to 500 dyne cm. A greater driving moment is easily obtained by enlarging the armature, but only at the exponse of increased weight of moving parts and a consequent increase in friction. We shall be fairly stating the result of careful designing if we put the driving torque at 15,000 and the moment of frictional resistance at 300 dyne cm.; in other words, driving torque at full load amounts to about fifty times the frictional resistance. It will be convenient to reduce these figures to percentages by calling the full load 100, maximum driving moment 100, and the friction moment 2, arbitrary units. We may also reckon full speed of the meter as 100 revs. per min. Our hypothetical meter will obviously not start until the load exceeds 2. Also it will make 98 revs. per min. at full load, since of the total driving torque of 100, 2 units are used up for friction, leaving 98 to work on the brake. Hence a table of corrections can be written down at once, on the assumption, of course, that friction is constant throughout the range of speeds contemplated. If there is no fluid friction this assumption is correct. The errors of the meter are given in Table I.

Table I.—*Errors of Uncorrected Motor Meter.*

Maximum driving torque = 100, friction = 2. Full speed = 100; arbitrary units.

Driving moment M.	Friction *f*.	Speed (numerically equal to M − *f*.	Percentage error.
2	2	0	inf.
4	2	2	−50
10	2	8	−20
20	2	18	−10
40	2	38	− 5
60	2	58	−3·3
80	2	78	−2·5
100	2	98	−2·0

Standard range = 1 to 3·3

It will be observed that with such a meter the consumer gets a discount of 16 per cent. when he is taking one-tenth of full load.* The range of a meter within specified limits of error forms the best criterion of comparison as regards accuracy, and the author proposes to call that part of the total range of a meter in which its error is within the limits imposed by the Board of Trade "the Standard Range." Hence the standard range of the hypothetical meter is 1 to 3·3 when the meter is adjusted to register correctly at full load.

Correction for Friction.—Clearly the simple uncorrected motor meter requires some modification before it can be considered as a practical instrument. It is well known that friction can be partially corrected by means of a starting coil in the pressure circuit. At first sight this seems a simple and sufficient solution of the problem. If to the hypothetical meter we add a starting coil whose driving moment on the armature equals 2, the errors in Table I. disappear. A new error will, however, have crept in; the meter will almost invariably run when the load is zero; lessen the strength of the starting coil, and the meter, although not quite so immoral, will still occasionally go on running when the load is off. The author was for a long time completely baffled in his efforts to find an explanation of this effect, but a very simple cause was at last discovered, and as others may have been puzzled besides himself he ventures to give the explanation here.

Every one knows how enormously the friction of light mechanism may be reduced by vibration. The reduction is far too large to be accounted for by the vibration causing cohesion to vanish. Now when a meter is fixed in a town house it is never entirely free from vibration, and the light axle such as is commonly employed in meters is alternating between a position in which it is wholly or partially out of contact with its bearings, and one in which it presses on them with more than normal force. In one sense, of course, the average value of friction remains the same as it would be with no vibration, and, in fact, the constant of a meter is hardly altered appreciably by it; but the fact that friction is higher during one half period of the shaking and the meter therefore at rest (the starting coil is supported just to balance the average friction—it is obviously insufficient to move the armature while the friction is above the average) does not prevent the starting coil from moving the armature during the half periods when friction is less than the average. The author has found that a meter fixed to the brick wall of the office building at Woodfield Works would go on running all night when the driving moment was reduced to a very small fraction of that required to balance the normal average friction; and this can only be accounted for on the assumption that during what may be called the positive half periods of vibration the meter axle and commutator were to all intents and purposes frictionless. If this is the true explanation of a well-known trouble, then it is obvious that there will always be a difficulty with such meters when they are fixed in buildings subject to vibration.

Elimination of Friction.—Instead of regarding friction as unavoidable and attempting to correct for it, the author has approached the problem from another side and endeavoured to remove the causes of friction and so avoid the necessity for correction. These causes are, as has already been stated, (1) friction of axle bearings, (2) friction of brushes on commutator, (3) friction of counting train and gear connecting it with the motor axle. With an ordinary vertical axle the first is nearly all due to the bottom or step bearing, which is usually a rounded steel point resting in a jewel cup. In the author's meter the pressure of the axle on the bottom bearing is reduced to a few grammes by magnetically suspending the axle, armature, and brake. A top bearing is entirely dispensed with, the axle being held in position magnetically—"magnetically pivotted."

The brush friction is enormously reduced by the use of a novel form of commutator having elastic segments against which the edges of two light and freely pivotted wheels roll to act as brushes. The friction of the train is entirely removed as a source of error. The train is driven by a simple electro-magnetic device whose speed of working is controlled by the speed of the motor, although there is absolutely no mechanical connection between them.

These means have already sufficed to reduce the friction from a value between 300 and 400 dyne cm. to less than 3 dyne cm., and there is reason for believing that the limit has not yet been reached.

Early Attempts at Magnetic Suspension.—The possibility of using magnetic force to take the weight of the rotary parts of a motor meter off its bearings has no doubt presented itself to many minds, and probably a good many inventors have made experiments with that object in view. In 1887 Mr. Hookham refers to the subject in one of his meter patents, but he confines himself to the statement that "the magnets may be so disposed as to counteract or partially counteract gravity, and thereby lessen friction."* A little later Mr. Ferranti turned his attention to magnetic suspension in connection with alterate-current meters, while quite recently in America Mr. Stanley has brought out a motor meter in which the vertical axle is entirely suspended by means of the attraction of iron discs fixed on the axle and ring poles surrounding them. Pivots at the top and at the bottom of the axle are required to keep it and the discs exactly concentric with the ring poles, the relative position of the discs and ring poles being one of unstable equilibrium laterally, although perfectly stable axially.

The author began experimenting with magnetic suspensions a few weeks after the publication of Prof. George Forbes' Paper on his "windmill" meter. It occurred to him that the Forbes meter might be made less wasteful of power if it were compounded much in the same way as a steam turbine, and he proposed to make the compound windmill as nearly frictionless as possible by magnetically suspending the axle and its series of rings of vanes. A meter was made on this plan with a bar magnet placed in line with and immediately above the end of the axle, which was pivotted top and bottom (see Fig. 1); the arrangement proved quite unworkable and was abandoned. In 1891 the author, in connection with Mr. Vignoles, was working at a motor meter of the Ayrton-Perry type, in which friction was eliminated by floating the armature in water or oil. The armature was held in the centre of the vessel containing the liquid by means of a little iron rod projecting axially below the armature, with its end close to the bottom of the vessel (Fig. 2). A bar magnet was fixed underneath the vessel, in line with the iron rod, and with its upper pole as close as possible to the bottom of the vessel. The iron rod was consequently held in the magnetic axis of the bar magnet, and the axis of rotation of the rotary system coincided with the magnetic axis. This "magnetic pivot," as it was called, worked admirably, but the meter itself was a failure.† Another application of magnetic suspension was attempted in 1891-2 in connection with an early form of the Richards-Evershed Ships' Telegraph. In this apparatus a very powerful magnet is

* Through the kindness of Prof. Ayrton the author has been able to test an actual meter made in the manner described. Its maximum driving torque was 19,000 dyne cm., and its friction 350 dyne cm., the accuracy being therefore rather better than that shown in Table I. But this was dearly purchased at the expenditure of no less than 10 watts in the pressure circuit.

* Specification of Patent No. 4,225**, 1887.

† It is worth mentioning that the train of this meter was to be driven by a coil with a vertical axis fixed on top of the armature and alternately attracting and repelling a magnet, an idea which has, after the lapse of nearly ten years, been tested and proved to be entirely practicable.

Digitized by Google

required to be freely pivotted and to have as little inertia as possible. An induced magnet was tried, magnetised by induction from an electromagnet. The induction was led from the fixed to the movable magnet through the ends of the axle as shown in Fig. 3. The arrangement gave much trouble owing to the magnetic attraction forcing one or other of the pivots against the end of its bearing. In a modified form (see Fig. 4) the induction was led into the axle radially, and at the same time a little axial displacement was given to the enlarged part of the axle with respect to the fixed ring pole in order to relieve the bottom bearing of the weight of the magnet N N and its heavy axle. This was accomplished to some extent, but two new difficulties arose: if the axle was not absolutely concentric with the hollow poles of the fixed magnet, there

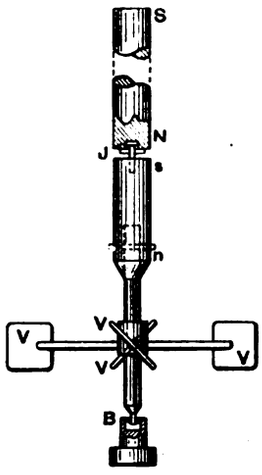

Fig. 1.—Magnetic Suspension applied to Professor Forbes' "Windmill" Meter.

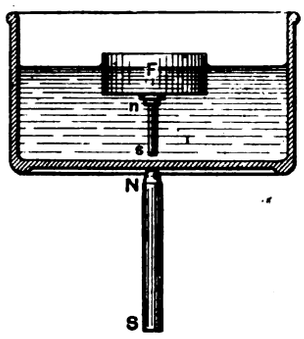

Fig. 2.—Magnetic Pivot applied to the Floating Armature of a Motor Meter.

was a lateral magnetic pull upon it, causing the pivots to bear with corresponding pressure on their bearings, so that the elimination of one friction had only served to introduce another; the other difficulty arose from want of perfect mechanical truth in either the axle or the ring poles, or both. This led to the ring poles having a directing moment on the axle, and gave rise to errors in the indications of the telegraph. In a sense, these troubles were due to imperfect workmanship and were consequently avoidable. But anything requiring great nicety of adjustment was quite out of place in the particular apparatus of which the movable magnet formed a part, and after much fruitless work all idea of magnetic suspension was given up and the whole magnetic circuit was made to move as one piece.

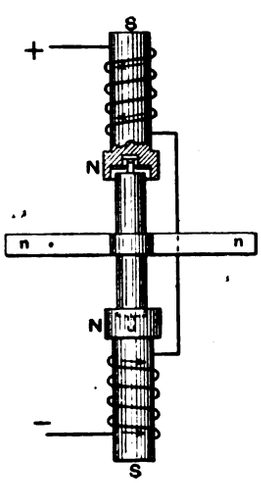

Fig. 3.—Magnetic Suspension, applied to the Needle Axle of a Ship's Telegraph.

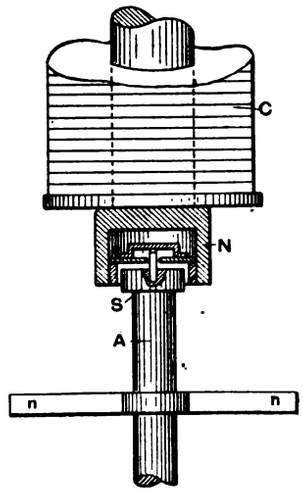

Fig. 4.—Modified Form of Magnetic Suspension for a Ship's Telegraph.

In a renewed attempt to make a frictionless meter of the Ayrton-Perry type, the weight of the rotary part was suspended by the attraction of a fixed solenoid surrounding the upper end of the iron axle (Fig. 5). The magnetic circuit was made as perfect as possible by fixing an iron disc on the axle just below the coil and carrying an iron tube up from the disc so as to partially enclose the coil. It was, however, not found practicable to reduce the waste of power in the solenoid below about 5 watts, and this was quite sufficient to put this form of suspension out of court so far as motor meters are concerned.

Present Form of Magnetic Suspension.—Finally, the author returned to the first idea (Fig. 1) of a simple magnetic pole fixed above an iron axle. Experience had proved that one of the worst troubles with all forms of supension was caused by the magnetic axis not being absolutely coincident with the rotational axis, the latter being determined by the pivots. If the top pivot is removed, the axle is free to centre itself in a magnetically symmetrical fashion, and it will then rotate about the magnetic axis (Fig. 6.) Any directional moment due to the axle and suspending pole not being perfect figures of revolution will be enormously reduced by diminishing the diameters of axle and pole; and with diameters not much exceeding 5mm. the supporting pole has no measurable directing influence upon the axle. Thus the combination of the suspension shown in Fig. 1 (minus its top pivot) with the magnetic pivot of Fig. 2 has resulted in a perfectly practicable and very simple arrangement for relieving a step bearing of the greater part of the weight of the rotating system.

To prevent the axle from accidentally coming into contact with the supporting pole, a thin plate of non-magnetic metal (seen at *e* in Fig. 6) is interposed between them. It is fixed immediately above the end of the axle, leaving a very small clearance. The supporting pole is adjusted until nearly the whole of the pressure on the step bearing is relieved. If the pressure is reduced to zero, a slight shake will jerk the axle up until it rests against the plate, where it will remain, since the upward attracting force increases as the space between axle and supporting pole diminishes. It is therefore necessary to leave a few grammes weight unbalanced so that there is sufficient gravitational force downwards to pull the axle off the end-plate, should it happen to rise into contact with it.

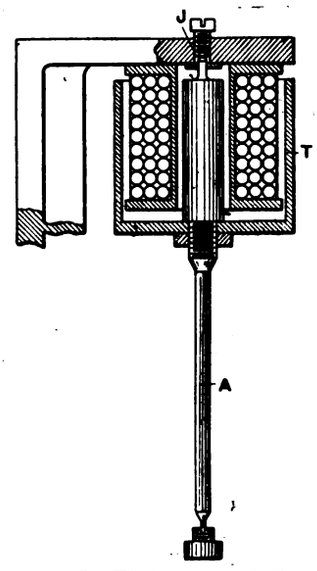

Fig. 5.—Electro-magnetic Suspension applied to a Motor Meter.

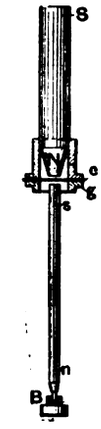

Fig. 6.—Present Form of Magnetic Suspension applied to a Motor Meter.

Essential Points in Magnetic Suspension of Meter Axles.—Magnetic attraction has been used to partially support the weight of dynamo armatures by the simple expedient of boring the pole pieces excentrically. Again, if a dynamo has a vertical axle, the whole of the pressure upon the step bearing may be removed by allowing the armature core to fall a little below the level of the pole pieces; but these and similar applications of magnetism to the relief of bearing pressure must not be confounded with its use as a means of reducing the resistance to rotation of a meter axle.

Our object in magnetically suspending the axle of a motor meter is twofold. It is certainly an advantage to reduce wear and tear of bearing, but primarily we desire to improve the meter as regards accuracy and waste of energy, and to that end it is essential that there should be a reduction of all the resistances to rotation other than that offered by the brake. Now, while it is easy to suspend a meter axle by some such means as those just referred to as applicable to dynamos, a moment's consideration shows that in reducing the friction of the step bearing to zero, we have at the same time introduced a new source of friction, namely, hysteresis in the iron core on which the two pole pieces act. This, as is well known, offers a resistance to rotation. Its amount in any practical example will be found to be enormously greater than the frictional torque of the step bearing. In a dynamo or motor the hysteresis torque is there in any case, whether we suspend the armature or not, so that the relief of bearing friction by displacing the armature in the pole pieces is a clear gain, but in the meter there is no iron core within the armature, and in order to suspend the axle in the same way a core must be put upon the axle for that purpose, thus introducing a resisting torque which did not exist before.

Digitized by Google

We thus arrive at an essential principle for magnetic suspension of meter axles: *The induction density in the magnetic devices used for support must remain absolutely constant during rotation of the axle.* This at once disposes of unsymmetrical bipolar arrangements; nothing of the nature of two poles attracting a piece of iron will serve. To secure uniform induction density in the rotating part of the magnetic circuit, the attracting pole must be a figure of revolution with its axis coincident with the axis of rotation. As an example, the attracting pole might be a ring concentric with the axle; an iron disc fixed upon the axle a little below the plane of the ring pole would be attracted upwards, and if the ring and disc could be made mechanically true and magnetically homogeneous, the induction density would be uniform in the disc and there would be no resistance to rotation due to hysteresis. In practice it is exceedingly difficult to ensure these conditions. The disc is in unstable equilibrium transversely, and as there is necessarily a little clearance between the axle pivots and their bearings, the disc will always run a little out of centre; this at once raises the density at one part of the annular air-gap and lowers it on the opposite side, and during rotation the iron of the disc goes through a minute magnetic cycle, absorbing a corresponding amount of energy. The disc is also pulled sideways and causes the pivots to press against the bearings. These effects were very marked in the experimental devices already referred to (Figs. 3 and 4) and led the author to abandon that type of suspension for the simple form finally adopted, namely, a cylindrical magnetised rod fixed with its lower end immediately above and in line with the cylindrical iron axle.

It must not be supposed that this is a complete solution of the problem; but it has proved itself to be a thoroughly practicable one, and if the diameter of the supporting pole and axle is small enough, there appears to be no trace of hysteresis, nor is any difficulty experienced in obtaining the requisite mechanical truth. Of course the position of the axle is one of unstable equilibrium in a vertical direction, the magnetic attraction increasing rapidly if the axle rises towards the supporting pole. But if means are adopted to confine the possible travel of the axle within narrow limits, it will run with very little pressure on the step bearing.

(To be continued.)

ELECTRICITY WORKS ACCOUNTS.

The City of London Electric Lighting Co. (Ltd.).

The retrogression in the financial results of this undertaking, as shown by the accounts for 1899, is hardly surprising in view of the altered conditions brought about by competition.

As may be noticed from our table, the increase in the ratio of costs to revenue and the falling off in the profits are almost wholly due to the reduction in the revenue. The costs have slightly increased, however, the chief source of increase being in the fuel item as a result of the coal trade dispute last year. We are sorry to find that the repairs and maintenance item has risen from what was a very satisfactory figure in 1898. The wages item also shows an increase, but at 0·86d. per unit is not unsatisfactory. The result of these increases in the several items becomes marked in the total generating and works costs, which stand at figures quite 0·5d. too high. The management and property charges have dropped to a most reasonable figure at not quite 0·7d. per unit.

So far as the progress of the concern in the accession of new business goes, the figures of the output and lamp connections have a brighter aspect. The output at 8,549,353 units sold shows an increase of 23·2 per cent., while the equivalent 8 c.p. lamp connections show an advance of 19·4 per cent. The load factor has also slightly increased, having been 10·7 per cent., as compared with 10·2 per cent. in 1898. As showing to some extent the history of the development of the company's business the following table is reproduced:—

Dec. 31.	1892.	1893.	1894.	1895.	1896.	1897.	1898.	1899.
No. of consumers	242	1,080	2,740	4,230	4,303	6,32[illegible]	7,414	8,737
Equiv. 8 c.p. lamps con.	20,241	65,341	135,460	195,317	247,785	296,012	355,825	437,612

As in the 1898 accounts, we have departed from the rendering of the official accounts in respect to the repairs and renewals items. In the company's printed accounts these charges are debited to the depreciation fund, and are not included in the costs of generation and distribution. The following are the details:—

Year.	Total.	Repairs and renewals at station. Total at station.	Buildings.	Boilers, heaters, &c.	Engines and condensers.	Dynamos and exciters.	Other machinery, instruments, and tools.	Repairs, maintenance, and renewals of mains, lamp-posts and transformers.
1898	£12,426	£8,820	£1,153	£2,986	£1,428	£874	£2,379	£3,606
1899	19,120	14,729	1,995	5,200	2,037	981	4,516	4,391

Following our course last year the above £19,120 has been included in the costs in our analysis, although there is no data to show what part, if any, is legitimately chargeable to "depreciation" or "renewals." The result is, of course, to show a smaller working profit and allocation to depreciation than is shown in the official accounts.

The Bromley (Kent) Electric Light and Power Co. (Ltd.)

To have produced the satisfactory financial return and the costs figures shown in our second table in the first year of working and under the adverse conditions of situation, small output and low load factor is a result upon which the engineer of this little undertaking is to be congratulated.

During 1899 the total output sold was 110,958 units, of which 79,500 were sold for consumption in Bromley, and 31,458 units were transmitted to the sub-station at Chislehurst. At this output, and with a maximum supply demand of 200 kw. the load factor was 6·33 per cent. At such a low figure the fuel charge of 1·19d, per unit is really most satisfactory. The other elements of generating costs are remarkably low, and were the works and total cost figures higher by 0·5d. per unit than they actually are we could not have adversely criticised them.

At 5·84d. per unit, the revenue figure practically represents the average, irrespective of output and load factor, and it must be highly gratifying to be able to show with such a tariff and upon so small an output a working profit of 2·74 per cent. of the expended capital in the first year. We only hope that it will be found possible to maintain the position of 1899 in the current and succeeding years.

The following is a list of electric supply works the accounts of which have been analysed, together with the dates on which statements and analyses of accounts have appeared:—

The Electrician.

The Oldest Electrical Journal (established as a weekly Journal 1861—1878

Published every Friday, Price Sixpence; Post Free, Sixpence-Halfpenny.
Editorial Publishing and Printing Offices,

, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.

Telephone: 949 Holborn. *Telegrams:* "Electrician Newspaper London."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher "The Electrician," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "The Electrician" *Printing and Publishing Company, Limited, and be crossed* "*Coutts and Co.*"

All Editorial letters to be addressed to The Editor.

All letters for insertion in "The Electrician," *or containing questions, must be accompanied by the name and address of the writer as evidence of good faith. No notice whatever is taken of anonymous communications.*

"The Electrician" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices, as above*

Subscription Rates.—The Rates for Subscriptions to "The Electrician" are as under:—

	Year	Half-Year	Quarter	
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.	Post free, payable in advance.
Postal Union	30s. 0d.	16s. 0d.	8s. 6d.	

New Volumes of "The Electrician" *commence in April and October.*

"The Electrician" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.** *This statement is guaranteed.*

Advertisement Rates, &c., forwarded on application to the Publisher.

Trade Advertisements *intended for the current issue must reach the Office not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday. Wrapper Advertisements by Wednesday morning.*

Official Announcements, Auctions, *and* Small Advertisements *accepted up to 6 p.m. on Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of The Electrician" *Printing and Publishing Company, Limited. The well-known* "Electrician" Series *of Standard Electrical Works at present consists of—*

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. Elton Young, M.I.E.E. Price 10s. 6d., post free; abroad 11s.

THE STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By Messrs. H. K. C. Fisher and J. C. H. Darby. Price 6s. net; abroad, 6s. 3d.

BIBLIOGRAPHY OF X-RAY LITERATURE AND RESEARCH. Edited by C. E. S. Phillips. With an introduction on the history of Crookes Tube and Röntgen Ray work, and a chapter giving "Practical Hints" on the subject.

THE POTENTIOMETER AND ITS ADJUNCTS. By W. C. Fisher. Price 6s., post free.

LOCALISATION OF FAULTS IN ELECTRIC LIGHT MAINS. By F. C. Raphael. Price 5s., post free.

MOTIVE POWER AND GEARING. By E. Tremlett Carter. Price 12s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. Wilkinson. Price 12s. 6d., post free.

ELECTRICAL LABORATORY NOTES AND FORMS (Elementary and Advanced). Arranged by Dr. J. A. Fleming, M.A., F.R.S. Printed particulars on application.

ELECTROMAGNETIC THEORY. By Oliver Heaviside. Vol. I. Price 12s. 6d., post free 13s. Vol. II. Price 12s. 6d.; post free, 13s.

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. Fleming. VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. New Edition. Price 12s. 6d., post free. VOL. II:—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. New Edition. 93 original illustrations, price 6s

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof J. A. Ewing, M.A. New edition. Price 10s. 6d., post free.

ELECTRIC MOTIVE POWER. By A. T. Snell. 10s. 6d. post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. George Gore. Price 10s. 6d.; post free.

ELECTRO-CHEMISTRY. By Dr. George Gore. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. Kennelly and H. D. Wilkinson. Price 6s. 6d., post free.

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. Weymouth. Price 7s. 6d. post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By Gilbert S. Ram. Price 7s. 6d., post free.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. Geipel and H. M. Kilgour. Price 7s. 6d. net, post free 7s. 9d., abroad 8s.; large-paper edition, 12s. 6d., post free. New edition in the press.

"THE ELECTRICIAN" PRIMERS. In Two Vols. Paper covers, 2s., post free 2s. 2d. each; strong cloth 2s. 6d., post free 2s. 9d. each. Single Primers 2d., post free 2½d.

WIRELESS TELEGRAPHY: Signalling across Space without Wires by Electric Waves. By Dr. O. J. Lodge. New Edition. Price 5s. net.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING, ELECTRIC TRACTION, TELEGRAPHS, TELEPHONES, &c. A. C. Curtis-Hayward, B.A. To January, 1900. Price 3s. 6d., post free.

CARBON MAKING FOR ALL ELECTRICAL PURPOSES. By Francis Jehl. Price 10s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d., post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. Beaumont. Price 3s. 6d., post free.

FULL CATALOGUE POST FREE ON APPLICATION.

"ELECTRICIAN" SERIES FORTHCOMING BOOKS.

THE ELECTRIC ARC.—By Mrs. Ayrton. This work is in the press, and will contain an historical sketch of the early experiments on the electric arc, as well as the important results of recent research.

PRIMARY BATTERIES.—A work on this subject will shortly be published bringing the theory and practice of the Primary Battery up to date. The book will be fully illustrated.

SECONDARY BATTERIES.—By E. J. Wade. Fully illustrated. The Author in this work will deal briefly with the theory and fully with the chemistry, design, construction and manufacture of secondary batteries or accumulators.

"THE ELECTRICIAN" WIREMAN'S POCKET-BOOK.—Edited by F. C. Raphael. "The Electrician" Company will shortly publish a valuable pocket-book for the use of those engaged in wiring work, both external and internal.

THE TELEPHONE.—By Dane Sinclair and F. C. Raphael.

SPECIAL NOTICE.

NOW READY.—Vol. XLIV. of "The Electrician" (950 pages), bound in strong cloth. Price 17s. 6d., post free [illegible] Cases for binding. Price 2s., by post 2s. 3d.

A complete set of "The Electrician" (1878-1900) can now be supplied. These sets are very scarce, and early application should be made.

INVENTION.

The establishment of a college for inventors is apparently the aim of a writer in the June number of *Cassier's Magazine*. Mr. W. H. Smyth, the author of the article we refer to, desires to "systematise inventive effort," and his arguments, even if they do not convince us of the necessity for an organised effort in this direction, are interesting reading, in spite of an occasional lapse into the involved style of diction peculiar to some American writers. However, to quote Mr. Smyth:—"Verbal statement, particularly in the inflexible form of written language, is but a clumsy tool for analytical processes which are difficult, even when expressed in terms of mental material with all its infinite plasticity. It, however, must serve, if lamely, to indicate the suggested method." On this plea, therefore, we may excuse the wording of the appeal itself, and also the logical subtleties in the opening paragraph:

> The inventive faculty is recognisable solely by its product. The Courts and Patent Office say that an invention is recognised solely by being the product of the inventive faculty. Assuming these propositions to be true which is to be the criterion, the faculty of the product, or the product of the faculty? Then, what shall constitute a test of the criterion itself—a test by which to settle that ever-recurring question of the presence or absence of invention in the production of patented devices and those on which patents are refused by the patent office?

We will, however, leave on one side the question as to the definition of an invention from the legal aspect, and turn to the main subject of the article—viz., to what extent the work of practical inventing may be fostered. The first part of the article is devoted to proving that an invention is not a spontaneous creation of the inventor, but is merely the outcome of a number of almost invisible steps, the Patent Office probably rendering the individual steps more visible than they otherwise might be. To illustrate this, an example is chosen of an invention which at first sight might appear to lack every suggestion of evolution, viz., that of the hydraulic dredge, and it is shown that it has in reality taken ten years for this invention to have been created, and that it is actually the outcome of a series of inventions approaching gradually nearer to the final realisation of the machine in question. That such an invention should take so long to evolve shows, says the author, "an amazing lack and need of system, order, and method in the direction of effort, and a

Digitized by Google

most prodigious waste of time and vital energy as a result of this unscientific, haphazard empiricism." But at this point, we think, Mr. SMYTH'S reasoning is at fault. Delay in the evolution of an invention is not due to the absence of logical system in the minds of inventors, but rather to the impossibility of the would-be inventor being able to acquaint himself with all that has been done in a direction likely to assist him to the required end. This is the reason that "inventors, as a class, have been almost invariably recruited from makers," for the maker has the best opportunity, in the pursuance of his own business, to observe the trend of invention in manufactures kindred to their own. But Mr. SMYTH'S argument is just the opposite of this. He unfairly considers that makers are devoid of the mental training necessary to an inventor. "They still depend," he says, "on their hardly-acquired manual skill, and have not yet learned to use the higher form of dexterity which employs the infinitely plastic images and concepts instead of refractory physical things themselves. The art is yet in embryo whose craftsmen consciously, skilfully, and intelligently employ that wonderful mental handicraft which has been unconsciously attained with, and by reason of, the acquirement of physical manual skill."

In the example chosen by Mr. SMYTH to illustrate his argument, he unconsciously proves that his view is erroneous. He takes the case of the heat engine and works out by his system of logical deduction what are the requisites for the invention of a more economical engine than we have at present, and what are probably the directions in which the inventor must work to attain this object. The conclusions he arrives at have, for long past, been well known to makers and designers of heat engines; many have been already engaged in research on more or less the same broad lines as he indicates, and it is extremely doubtful whether the wished-for revolution in gas engine design would be precipitated by the formation of a chair for "invention" at one of our colleges any more than by the nomination of an additional professorship in Sanskrit.

THE ELECTROLYTIC PRODUCTION OF SOLUTIONS OF HYPOCHLORITE FOR BLEACHING AND DISINFECTING PURPOSES.

BY JOHN B. C. KERSHAW, F.I.C.

I.—Introduction.

The production of bleaching compounds by the electrolysis of solutions of the alkali metal chlorides or of magnesium chloride, has for many years attracted the attention of practical electro-chemists; and the names of Hermite, Stefanow, Kellner, Woolf, Corbin, and Vogelsang are only a few of those connected with work in this particular branch of electro-chemistry. Ahrens, indeed, states* that so long ago as 1820 Brand bleached cotton goods between platinum electrodes by aid of the electric current; and this method of preparing bleaching solutions is clearly indicated in Charles Watt's Patent, No. 13,755, of 1851, which may be regarded as the master patent of the electro-chemical industry.

The principle of electrolytic bleaching depends upon the production of hypochlorite of sodium or magnesium, by combination of the chlorine liberated at the anode, and the hydrate formed at the cathode, when sodium or magnesium chloride solutions are decomposed by the electric current. The changes involved when a solution of sodium chloride is the electrolyte are chemically represented as follows:—

1.	$2NaCl$	=	$2Na$ (cathode)	+	$2Cl$ (anode)
2.	$2Na + 2H_2O$	=	$2NaOH$	+	H_2
3.	$2NaOH + 2Cl$	=	$NaClO$	+	$NaCl + H_2O$

* *Elektrochemie*, Stuttgart, 1896.

Equation (1) represents the primary results of the electrolysis of the salt solution; (2) and (3) represent the secondary reactions which end in the production of hydrogen gas, sodium chloride, sodium hypochlorite, and water. Two molecules of salt thus yield one molecule of sodium hypochlorite. The above reaction between the chlorine and sodium hydrate only takes place at low temperatures; if the solution becomes heated, chlorate is produced. The conditions requisite for the production of bleaching solutions by electrolysis are, therefore: (1) Insoluble electrodes, (2) no diaphragms, (3) low temperature of the electrolyte, (4) rapid circulation of the electrolyte from the cathode towards the anode.

The forms of cell which have been devised to attain these conditions have naturally many features in common, and it is only in minor details of construction that they differ one from the other. The tendency now to be observed in the textile industries in many countries to adopt electric transmission of power, is one which will hasten the development of the electrolytic bleaching industry, for it is evident that when a large factory already possesses an electrical generating plant for lighting and power purposes, the use of a fraction of this power for the preparation of bleaching solutions will be a comparatively simple matter. In such cases the addition of an electrolyser and two storage vats will be all the additional plant required. The subject of electrolytic bleaching is therefore of considerable interest at the present moment, and in the succeeding portions of this article the writer intends to describe the various forms of cell now in actual use, and to examine some of the published figures bearing on the relative costs of the older and newer methods of bleaching.

II.—Electrolysers for Production of Hypochlorite now in use.

The Hermite Electrolyser.—One of the earliest forms of Hermite electrolyser was patented in 1884, and the patent is therefore now extinct. The form eventually adopted in the various trials with this process consisted of a long, shallow open tank, containing two sets of revolving zinc discs, which acted as cathodes. These discs were entirely immersed in the electrolyte, and between each was fixed a platinum gauze anode, carried in a glass or ebonite frame. A solution of common salt and of magnesion chloride was used as the electrolyte, but owing to the difficulties caused by the adhesion of magnesium hydrate to the face of the zinc cathode the use of the latter was discarded. A solution of salt alone is, therefore, now used, or sea water where it is obtainable. The form of electrolyser described above has been used at Stjernfors, in Sweden, since 1890 for bleaching cellulose, and it has also been used experimentally at Havre, Worthing, Ipswich, Lytham, Bombay, Netley Hospital, and Marseilles for disinfecting purposes. These trials have not resulted in any permanent success; and, as regards sewage purification, the Hermite process is unlikely to be heard of again. At Stjernfors, however, and one or two other places, the cell and process are understood to be still in use for bleaching purposes, and at the former place 75 H.P. is said to be utilised. According to the figures supplied for the work of the Hermite electrolyser by Roscoe and Lunt* 10·2 E.H.P. hours yield 1 kilogramme chlorine in the form of hypochlorite.

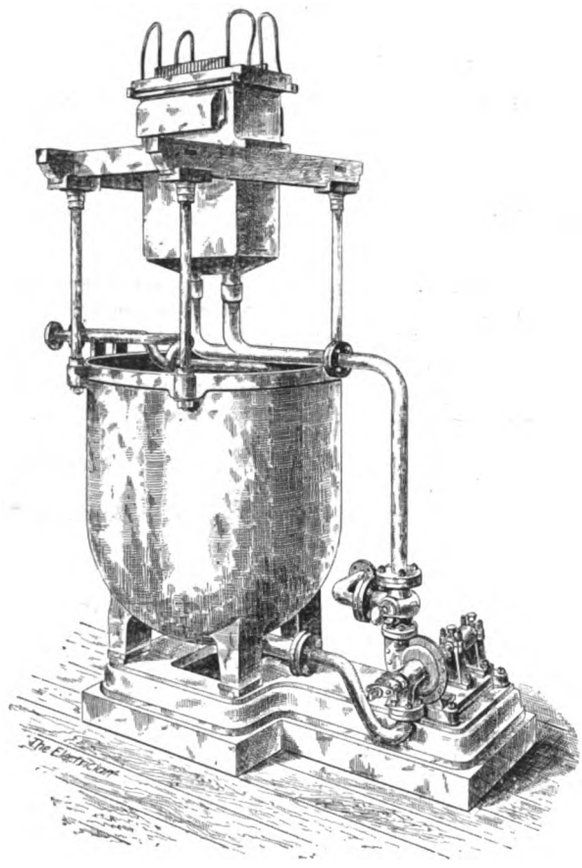
The Stefanow Electrolyser.—This form of electrolyser is reported to be extensively used in the textile industry of South Russia, but the writer has not been able to obtain much detailed information concerning it. The cell is believed to closely resemble the Hermite cell in its chief features, and a strength equal to 6 grammes free chlorine per litre is said to be attained. This result is facilitated by the use of lime with the solution of common salt. The lime probably prevents reduction of the hypochlorite already present in the solution, by the hydrogen liberated at the cathode, in the manner suggested by Oettel when discussing the electrolytic production of chlorates. No figures for the work of the Stefanow electrolyser are available.

The Kellner Electrolyser.—This electrolyser in its most recent form consists of an earthenware cell containing the electrodes, communicating with a centrifugal pump and an

* *Journ. Soc. Chem. Industry*, 1895, p. 224.

Digitized by Google

enamelled receiver, in which is placed a cooling spiral connected with the water supply. The salt solution is kept in continuous circulation by means of the pump through the electrolysing cell and the cooler, until the desired strength is attained. The electrodes are formed by winding platinum-iridium wire upon glass plates, and are stated to be highly efficient. The Kellner electrolyser is said to be used for the production of hypochlorites at Golling in Austria, at Sarpsfos in Norway, at Yorda in Hungary, at Lucerne, and at many places in southern Russia. Actual trial has shown that 114 amperes at 112 volts for 3 hours yielded 5·5 kilogrammes active chlorine. This is equivalent to 9·4 E.H.P. hours per kilogramme active chlorine.



The Dr. Kellner's Patent Electrolyser.

The Woolf Electrolyser.—This form of electrolyser as erected at Havana in Cuba, consists of a large wooden circular vat about 8ft. in depth, containing 417 positive and 425 negative electrodes placed ½in. apart. The positive electrodes are of platinum-iridium; the negative electrodes are of zinc. The electrodes are connected in parallel, and at Havana two electrolysing vats are run in series. Sea water is used as the electrolyte. At this plant 216 kw. electrical energy yield 935 kilogrammes active chlorine per 24 hours. This is equivalent to 7·5 E.H.P. hours per kilogramme active chlorine. The Woolf electrolyser has also been used with some degree of success at Brewsters and Rickers Island (New York) and at Danbury (Conn.) for disinfecting purposes; but the writer does not believe that these installations are now working.

The Corbin Electrolyser.—The Corbin form of hypochlorite cell is used at the cellulose factory of Messrs. Berges and Corbin at Lancey in France. The cell itself is built up of cement, and contains a large number of secondary electrodes of platinum-iridium foil. In order to prevent lateral dispersion of the current, these secondary electrodes are held in wide ebonite frames, and are placed only ½in. apart. A solution of common salt is used as the electrolyte and rapid circulation is provided for, by allowing the brine to flow in below, and to pass away over the top, by channels running round each of the four sides of the cell. The electrodes are therefore entirely submerged. The cells at Lancey contain 18 secondary electrodes and take 150 amperes at 120 volts = 18 kw. Each of these cells can produce liquor sufficient to bleach 750 kilogrammes cellulose per 24 hours. No details of the strength of this bleaching liquor are available; but it is stated that 150 kilogrammes bleaching powder would be required to effect the same work. Taking this as a basis of calculation, we find that 18 kw. in the Corbin hypochlorite cell yields 52·5 kilogrammes active chlorine. The consumption of electrical energy per kilogramme active chlorine is therefore 11·1 E.H.P. hours.

The Vogelsang Electrolyser.—This electrolyser is stated to be an improved form of the Stefanow apparatus. Each cell contains a large number of secondary platinised electrodes, and the number of these is arranged to absorb 65 or 110 volts. Further details of the construction of this electrolyser are lacking. A solution of common salt is used as the electrolyte. An electrolyser taking 85 amperes at 115 volts is said to produce bleaching liquor sufficient to bleach 4,000lb. cotton yarn in a 10-hour working day. This weight requires 20 kilogrammes active chlorine, and the yield of the Vogelsang form of electrolyser is, if these figures are trustworthy, 1 kilogramme active chlorine per 6·6 E.H.P. hours. The Vogelsang electrolyser is in use at a considerable number of textile factories and bleaching establishments in Germany.

III.—Comparative Costs.

The electro-chemical equivalent of chlorine is 0·0003672 grammes. Therefore 1 ampere hour will liberate 0·0003672 × 3,600 = 1·322 grammes chlorine, from a solution of common salt. Taking the minimum E.M.F. required to carry a current through the latter as 2·8 volts, the yield of chlorine per kilowatt hour is found to be 574 grammes. The equations given in the earlier portion of this article show, however, that for every two atoms of chlorine liberated at the anode, only one atom makes its appearance as active chlorine in the hypochlorite; and, therefore, *the theoretical yield of available chlorine* per ampere hour is 0·661 gramme, and per kilowatt hour is 287 grammes. Converting these yields into the form used for expressing the yields of the different electrolysers, we find that to obtain 1 kilogramme chlorine in the form of hypochlorite, theory demands an expenditure of current equal to 1,512 ampere hours, and of electrical energy equal to 4·73 E.H.P. hours.

In order that the yields of the various forms of electrolyser described above may be compared with that theoretically possible, the figures have been collected in Table I.; and the energy efficiencies have been worked out, using the theoretical figures as basis of the calculations. The results show considerable variation, ranging from an efficiency of 41 per cent. to one of 71 per cent. It may be observed that in such an electrolytic decomposition as that, by which hypochlorite is produced, the energy efficiency depends greatly upon the current density used, and also upon the arrangements made for circulating and cooling the electrolyte. The removal of the hydrogen gas liberated at the cathode has also great influence upon the results, since hypochlorite is readily reduced to chloride by nascent hydrogen.

In the absence of details concerning the current density used, the energy efficiencies given in Table I. are not of great practical importance; for it is evident that a high energy efficiency may be obtained under conditions which would not be economical in actual work. In electrolytic bleaching as in other electro-chemical operations, the problem is to find the point at which increased output per unit of plant ceases to be remunerative, owing to the increased E.M.F. required to operate each decomposing cell. Further, the question of losses in the external parts of the circuit must be taken into consideration. It is certain that these will be greater in the case of the Woolf form of electrolyser, with its 842 electrodes connected in parallel and its dynamos generating current at 12 volts pressure, than in those forms constructed to utilise a much higher E.M.F.

In the writer's opinion the most satisfactory form of electrolyser for hypochlorite production, is one provided with a large number of secondary electrodes, and thus capable of

Digitized by Google

Table I.—*Yields and Energy Efficiencies of various forms of Hypochlorite Cell.*

Name.	E.H.P. hrs. per kg. active chlorine.	Energy efficiency per cent.	Remarks.
Corbin	11·1*	42	No direct test of electrolysed solution.
Hermite	10·2	46	Roscoe and Lunt's figures, based on actual trials.
Kellner	9·4	50	3 hours' trial with 114 amperes at 112 volts.
Vogelsang	6·6*	71	No direct test of electrolysed solution.
Woolf	7·5	63	Estimated yield of plant per day.
Theoretical figures	4·73	100	...

utilising a fairly high E.M.F. between the two terminal electrodes. The Kellner, Corbin, and Vogelsang electrolysers are examples of this type.

In the remainder of this article, the figures for the Kellner electrolyser are taken, since they are apparently based on reliable trials, and they are a mean between those representing the work of the Corbin and Vogelsang electrolysers. A circular relating to the Kellner electrolyser † contains the following details of cost for the preparation of 650 litres of hypochlorite solution, containing 0·85 per cent. of active chlorine :—

	s.	d.
Common salt, 71·5 kilogrammes, at 16s. per ton	1	$1\frac{3}{4}$
Electrical energy, 19 H.P., for three hours, at 0·282d. per E.H.P. hour	1	$4\frac{1}{4}$
Depreciation, 10 per cent. for three hours		$9\frac{1}{2}$
Total	3	$3\frac{1}{2}$

The 650 litres of solution contained 5·5 kilogrammes active chlorine, and the cost per kilogramme was, therefore, $\frac{39{\cdot}5}{5{\cdot}5} = 7\frac{2}{10}$d.

It is somewhat difficult to obtain figures which shall represent the cost of an equivalent amount of chlorine in the form of bleaching powder, for losses occur in making the solution from the solid compound, and it is doubtful if on the average more than 90 per cent. of the 86 per cent. chlorine available in the bleaching powder is obtained in the bleaching liquor. The labour necessary for preparing the solutions is also greater in the case of bleaching powder, and may be reckoned at 20s. per ton. Allowing for these two increases, we find that the cost of 1 kilogramme available chlorine with bleach at £5 per ton at the point of consumption, is 4·8d., and with bleach at £7. 10s. per ton, is 6·8d. It is, of course, evident that the relative cost of the two bleaching agents depends chiefly upon the relative costs of electrical energy and of bleaching powder at the point of consumption. But the question of relative cost is not settled by the figures given above. Hypochlorite of soda is a more efficient bleaching agent than hypochlorite of lime (bleaching powder) and for many years it has been used for bleaching the higher classes of goods, in spite of its higher cost per kilogramme of active chlorine ‡ Not only is there no danger from particles of lime remaining in the fabric bleached, but less acid is required for scouring; and the bleached goods gain not only in colour, but also in strength. These advantages more than balance the slightly higher cost per kilogramme of available chlorine. In support of this statement, the following figures, representing the costs of actual trials with solutions prepared from bleaching powder, and from common salt by electrolysis, are given. They are taken from the circular already named, and the hypochlorite of soda solution was prepared in the Kellner electrolyser. The cost of the kilogramme of active chlorine in the electrolysed salt solution is taken at $7\frac{2}{10}$d.

First Trial.—2,800 kilogrammes of Light Calico Goods for Dyeing and Printing.

Electrolytic Method.	s.	d.
1,075 litres of solution containing 0·281 per cent. chlorine = 3 kilogrammes chlorine at $7\frac{2}{10}$d.	1	$9\frac{6}{10}$
60 kilogrammes hydrochloric acid at 4s. per 100 kilogrammes ..	2	$4\frac{8}{10}$
Total cost of chemicals.....	4	$2\frac{4}{10}$
Older Method, with Bleaching Powder.		
40·7 kilogrammes bleaching powder, at £7. 5s. per ton*	5	$10\frac{8}{10}$
200 kilogrammes hydrochloric acid, at 4s. per 100 kilogrammes	8	0
Total cost of chemicals.....	13	$10\frac{8}{10}$

Second Trial.—3,450 kilogrammes of Heavy Calico for White Goods.

Electrolytic Method.	s.	d.
1,250 litres of solution, containing 0·512 per cent. chlorine = 6·4 kilogrammes chlorine at $7\frac{2}{10}$d.	3	$10\frac{8}{10}$
115 kilogrammes hydrochloric acid at 4s. per 100 kilogrammes...	4	$7\frac{2}{10}$
Total cost of chemicals.....	8	$5\frac{4}{10}$
Older Method, with Bleaching Powder.		
50 kilogrammes bleaching powder at £7. 5s. per ton*	7	3
345 kilogrammes hydrochloric acid at 4s. per 100 kilogrammes...	13	$9\frac{6}{10}$
Total cost of chemicals.....	21	$0\frac{6}{10}$

In conclusion, the fact may once again be emphasised, that the use of electricity for lighting and power purposes is leading to a reorganisation of the internal arrangements of many of our mills and factories. In the textile industry the change is likely to be accompanied by a change in the method of bleaching, since hypochlorite of soda can now be produced as required, by a comparatively small addition to the electrical generating plant; and produced under favourable conditions in this way, it has been found by *actual trial* to be, not only an efficient, but also an economical bleaching agent.

PHYSICAL SOCIETY.

At an ordinary meeting held May 25, 1900, Prof. Everett, F.R.S., vice-president, in the chair, Prof. S. P. Thompson showed some

"Experiments Illustrating the Aberration Called Coma."

If a converging lens is placed obliquely in a parallel beam of light, instead of forming a point image, it produces unilateral distortion, and the bright central spot is accompanied by a pear-shaped tail which is known as a "coma." The direction in which this tail points depends upon the side of the lens which is presented to the light. With a concavo-convex lens the convex surface gives an inward pointing coma, and the concave surface an outward pointing coma. The existence of this phenomenon is due to unequal magnification from different zones of the lens, a fact which was shown by covering the lens with a zone plate of three or four rings and viewing on a screen the distorted images of the several zones. The form of a coma varies greatly with the distance of the screen from the lens. A parallel beam of light which has passed obliquely through a convex lens is capable of producing some curious shadows. The shadow of a rod can be obtained as a circular spot, and that of a grating made by stretching threads between rods, as concentric circular rings. Prof. Thompson also showed a stringed model illustrating the paths of the light rays in the formation of a coma.

Mr. R. T. Glazebrook then read some

"Notes on the Measurement of Some Standard Resistances."

Three methods have been employed by the author for building up multiples of a standard resistance, such as a 1 ohm coil. The first method consists in making as accurately as possible 3 ohm coils. These in parallel can be compared directly with the standard by Carey Foster's method. Their resistance in series is very approximately nine times that in parallel, and hence an accurate determination of a resistance about 9 ohms can be obtained. If then this resistance is put in series with the standard an accurately known 10 ohm resistance is obtained. By a similar process a 100 or a 1,000 ohm coil can be built up. The second method consists in calibrating a resistance box. The 1 ohm coils of the box are compared directly

* These figures are based upon the weight of bleaching powder required to perform the same work, and they are, therefore, less trustworthy than figures based upon actual tests of the electrolysed solutions. It is probable that the first is too high and the second too low.

† *See* also *Zeits. f. Elektrochemie*, Vol. V., p. 375.

‡ The higher bleaching efficiency of solutions of hypochlorite of soda, electrolytically prepared, is now explained as due to the presence of free hypochlorous acid. See *Zeits f. Elektrochemie*, Jan. 4 and 11, 1900.

* The bleaching efficiency of the hypochlorite solutions prepared by electrolysis, is in these two instances, three to five times greater than the efficiency of the solutions prepared from bleaching powder. This higher efficiency of the hypochlorite solutions prepared by electrolysis, first noted by Cross and Bevan, is now fully explained by the research work of Sieverts.—*Zeits. für Elektrochemie*, Vol. VI., p. 364, *et seq.*

Digitized by Google

with the standard, and the other resistances determined accurately by a building-up process, using a subsidiary resistance box. In comparing the high resistances the difference between the two boxes may be so great as to send the balance off the bridge wire. In these cases the third method is employed. The equal arms of the bridge are accurately known, and one of them is shunted with a resistance, which need not be accurately known, until the reading is brought back on to the wire. The coils chiefly used throughout the experiments are made of platinum-silver.

Mr. CAMPBELL asked if the same degree of accuracy could be obtained with manganin coils. If so, then the small temperature change of manganin would be an advantage.

Mr. TROTTER asked if proper allowance could be made for the large number of mercury cups used in method I.

Mr. RENNIE advocated the use of the build-up box in preference to the first method. With two mercury cups there is less chance of errors escaping notice than with eight. Every 10 or 100 ohm coil tested at the Board of Trade is subjected to a comparison with a box calibrated by a build-up process.

Dr. HARKER asked if the resistance of the eight mercury cups in series had ever been measured, and if so, what was the magnitude of the result and what the uncertainty.

Mr. GLAZEBROOK said he had investigated the resistance of the mercury contacts, and it was negligible. In answer to Mr. Campbell, the author said he had no experience of manganin coils himself, but he had seen some figures for German coils which agreed very closely.

Mr. J. J. GUEST then read a Paper

"On the Strength of Ductile Materials under Combined Stresses."

The author throughout his experiments has used the "yield point" of a material as the true criterion of its strength, and has rejected the elastic limit as being modified by local yielding. At present two theories are used in the calculation of strengths of materials. The first is that the material yields when one of the principal stresses reaches a certain amount. This theory, which was adopted by Rankine, and is used by engineers in England and America, is not in accord with recent experiments. The second theory is that the material yields when the greatest strain reaches a certain amount. This was advocated by St. Venant, and is used by engineers on the Continent. Besides these, there is a third theory of elastic strength, in which the condition of yielding is the existence of a shearing stress of a specific amount. In the case of a solid bar subjected to torsion there is a variation in the strain from the axis outwards, and consequently the materials have been used in the form of thin tubes. This allows the application of an internal fluid pressure. The specimens were of steel, copper, and brass, the state of set caused by drawing having been removed by annealing. The tubes were subjected to (1) torque, (2) torque and tension, (3) tension only, (4) tension and internal pressure, (5) torsion and internal pressure, and (6) internal pressure only. The axial elongation, the twist, and occasionally the circumferential strain were measured. Towards the end of the experiments observations were made on bending. The results disprove the maximum stress theory, and are at variance with the maximum strain theory. The maximum shearing stress developed and the corresponding shearing strain were comparatively constant throughout the experiments, and no other simple relation between the stresses or strains was even approximately constant. The results of the experiments have been plotted synoptically on a curve, and the several lines have been drawn upon which these points should be according to the various theories. It is readily seen that the points cluster round the line which represents the existence of a specific shearing stress. The author therefore favours the existence of this stress for any material.

The Chairman read a communication upon the subject from Dr. CHREE. Mr. Guest in his Paper has regarded the shearing stress theory as a little known one. As the shearing stress is half the difference between the greatest and least principal stresses this theory is the same as Prof. G. H. Darwin's maximum stress-difference theory. All the theories suppose that the stress-strain law is linear, and that strains are so small that their squares and products can be neglected. Mr. Guest concludes that in ordinary materials the law is linear to the elastic limit, which answers to a stress lower than that which answers to the yield point, and that yield point phenomena arise between these. Nevertheless he focusses attention on the yield point as the criterion of strength, and assumes that Hooke's law holds up to it.

Prof. PERRY congratulated the author upon his Paper, and said there was no time left to discuss it at length. The results obtained gave information upon a subject of which very little is known experimentally.

The Society then adjourned until June 8.

At an ordinary meeting held June 8, 1900, Dr. J. H. Gladstone, F.R.S., Vice-President, in the chair, a Paper on

"The Magnetic Properties of Alloys of Iron and Aluminium. Part II.,"

by S. W. RICHARDSON and L. LOWNDS, was read by Dr. Richardson. Experiments have been made to ascertain in what way the hysteresis loss, between given limits of the field strength, is connected with the temperature, for an alloy containing 3·64 per cent. of aluminium. The experiments show that the hysteresis loss attains a maximum value at a temperature considerably higher than the temperature of maximum induction. The changes produced in the magnetic properties of the alloy by heating and subsequent cooling have also been investigated. The properties depend largely on the previous history of the specimen, but there does not appear to be any essential difference between the behaviour of the alloy during heating and cooling (except near the temperature of minimum permeability). Experiments have also been conducted on the abrupt change in the permeability that takes place at a temperature of about 650°C. The conclusions arrived at are as follows:—(1) The hysteresis loss at first diminishes as the temperature rises. It then increases, and reaches a maximum at about 550°C. On further heating it falls off rapidly, and is negligible at 700°C. (2) The magnetic properties of the specimen depend largely on its previous history. (3) There is no essential difference between the behaviour during heating and cooling, except near the temperature of minimum permeability. (4) An abrupt increase in the permeability takes place at about 650°C. during heating followed by an equally abrupt diminution on further heating. (5) This abrupt change is more marked with falling than with rising temperatures. (6) Continued heating and cooling diminish the permeability. (7) The curve connecting temperature of minimum permeability and percentage of aluminium is a straight line. (8) The microscopic examination of the specimens shows the presence of crystals.

Prof. S. P. THOMPSON asked if the specimens had been kept for any length of time at a high temperature, because crystals changed and grew in metals at temperatures even far below their melting points.

Prof. REINOLD asked if any specimens had been examined where the crystalline structure had not been observed.

Mr. BLAKESLEY asked if any explanation of the orientation of the crystals could be given.

The CHAIRMAN said it was difficult to know exactly what substances were being dealt with. They might be pure alloys or mixtures of two or three alloys with iron or aluminium.

Dr. RICHARDSON, in reply, said the crystals might be dissolved in nitric acid and analysed, but at present he did not know their composition.

Mr. W. CAMPBELL then read a

"Note on Crystallisation Produced in Solid Metal by Pressure."

In the preparation of sections of tin, particles cling to the file and, if allowed to remain, tend to tear the surface of the metal. The effect is not immediately noticeable, but on etching the polished surface there appear, besides the usual structure of the tin, lines of much smaller crystals with irregular boundaries, but possessing different orientation. The effect is only superficial, because it can be removed by polishing. The same behaviour is noticed in some alloys, and it would thus appear that the pressure of a file is sufficient to cause a metal or an alloy to rearrange itself.

Prof. S. P. THOMPSON suggested that the effect might be due to local heating caused by tearing rather than to pressure.

Mr. CAMPBELL said the effect was not due to the heating of the file, because if the file were kept perfectly clean no crystals formed.

Prof. S. P. THOMPSON asked if scratching the surface with a diamond produced crystallisation.

The AUTHOR said he had tried with a sharp knife without success, but cutting with a blunt chisel produced crystallisation along the chisel mark.

A Paper on

"The Viscosities of Mixtures of Liquids and Solutions"

was read by Dr. C. H. LEES. Three formulæ have been suggested for expressing the viscosity of a mixture in terms of the percentages and viscosities of its constituent parts. The first of these represents the viscosity, as being the sum of a number of terms, each one of which is the product of the percentage of any constituent and its viscosity. The second formula represents the logarithm of the viscosity in a similar manner, and the third one the reciprocal. None of these formulæ represents the viscosity of a mixture with closeness. The author suggests a formula in which the mth. power of the reciprocal of the viscosity of a mixture is equal to the sum of a number of terms each one of which is the product of the percentage of any constituent and the mth power of the reciprocal of the viscosity of that constituent. This formula gives satisfactory agreement, and, moreover, leads to Slotte's formula for the variation of viscosity with temperature.

The Secretary read a note from Prof. WOOD, on

"An Application of the Method of Striæ to the Illumination of Objects under the Microscope."

The object chosen was powdered glass immersed in cedar oil of the same refractive index. The glass particles were almost invisible under ordinary conditions of illumination. The illuminating system was then arranged as follows:—A screen bounded by a straight edge was placed in front of an incandescent gas lamp so as to cut off half of the mantle and give a source of light bounded by one perfectly straight edge. A small lens of very short focus was placed below the stage as close as possible to the object. The lamp was at a distance of 6ft., and the light reflected from the mirror was brought to a focus by this lens, passing

Digitized by Google

through the object on its way. An image of the lamp was formed in space and viewed by the microscope. A little strip of thin brass with a carefully cut straight edge was fastened to the stand carrying the bull's eye condenser, and moved into position between the objective and object, so as to cut off the flame image with the exception of a narrow thread of light along the straight edge. The brass screen must be in the plane of the flame image with its edge parallel to the straight edge of the flame. The brass was then advanced over the flame until nearly all the light was cut off. Upon lowering the microscope until the object was in focus, and carefully advancing the brass strip until practically all the flame image was cut off, it was found that the glass particles suddenly appeared with great sharpness, showing as distinctly as if in air. Two photographs of glass in oil were shown, one taken with ordinary illumination and the other by the Schlieren-Methode.

The meeting then adjourned until June 22nd.

SOME CONSIDERATIONS CONCERNING ELECTRIC DRIVING.*

BY H. A. MAVOR.

The institution of public supply stations for the distribution of power is now well begun in this country, and is likely to show very important developments in the immediate future. It is not necessary to prejudge the case now being considered by a committee of the House of Commons to determine whether or not the public supply of power ought to be in the hands of the local or municipal authorities or in the hands of private companies. In either case the results as regards the practical requirements for the supply of motors are likely to be qualitatively, if not quantitatively, similar. The chief determining factor in the quantity of motors to be required will be the price for the supply of electrical energy. It seems probable that the price to be aimed at in the immediate future will be about 1d. per unit for a 500-volt supply on three-wire system. It is not probable that this price will be seriously reduced in such a time as need be considered for our present purpose. It is well known that large users of power can produce electric energy for their own purposes at or about this figure, and it is very unlikely that they would in any case draw upon the public supply, and therefore the demand is likely to come rather from users of small powers or of large powers in such an intermittent manner as to preclude economical production.

The fixing of a standard voltage of 500 and continuous current for public supply must necessarily tend to standardise private supply on the same lines, not only because of the convenience of interchange of sources of supply by the user, but because of the preference by the manufacture to supply a standard article. It may be assumed that the probable range of size of motors required for connection to public supply will be normally from about ½ H.P. to about 20 H.P. each. The lower limit is certainly far above the power required for many industrial operations, but the manufacture of motors below ½ H.P. for use, even on 250-volt circuit, is not likely to be satisfactory for two reasons: first, because of the high initial cost in proportion to the effective power, and secondly, because of the very inefficient working of the smaller sizes. In cases therefore where the individual units are smaller than ½ H.P., as for example, sewing machines, they will probably be grouped so as to utilise the larger sizes of motors.

From the user's point of view efficiency is usually a matter of secondary consideration until the experience of comparative bills of cost induce a more intelligent inquiry into the relative values of the motors. In the first instance the capital cost of the motor is too often allowed to be the sole determining factor in choosing it. The cost of the ½ H.P. motor may be taken at about £15, and the cost of running it nine hours per day for a year at 1d. per unit would be about £5, so that the calculation of the value of improved efficiency is a simple one, *i.e.*, a saving of 10 per cent. on efficiency on the motor would amount to 10s. per annum. The charge for interest and depreciation of £15 being taken at 30s., an increase of one-third in the price of the motor would be justified if it gave 10 per cent. better efficiency. This would approximately increase the size of the motor by about twice, and the argument is therefore a strong one in favour of spending money on material for the purpose of gaining increased efficiency on motors of this size. The smaller the machine is the greater the handicap under which it works. The use of smaller machines is attended with further disadvantage in the direction of frequent necessity for and difficulty in carrying out repairs.

Looking at the matter now from the manufacturer's point of view, let us consider how the probable demand for motors can best be met.

Motors of 5 H.P. to 10 H.P. present no difficulty. They can be economically designed and made at a reasonable cost. The smaller motors, on the other hand, if they are to be efficient working machines present many difficulties. The cost of material for the smaller machines of normal design as regards their magnetic and electric features bears a very high proportion to the total value of the machine, and the amount of labour to be expended upon these materials is made up of so many small items that it is extremely difficult to effect any material saving in cost. These facts apply more especially to the manufacture of small shunt-wound machines for high voltage. The manufacturer would therefore probably prefer to supply for the small sizes series-wound motors, and they may fairly plead the several advantages from the users' point of view to weigh in the consideration:—

A series-wound motor is more easily started with the load.

The maximum current required to give the starting torque is usually less in the series motor than in the shunt motor and therefore the starting resistance need not necessarily be so large, the resistance of the series-winding of the motor supplements the starting resistance.

As there is a much smaller number of turns of wire on the series motor the inductive effects on making and breaking the current are much less likely to cause damage to the motor and to the starting switch.

Series motors can be designed to give a comparatively small variation of speed within ordinary working limits if they are properly applied to the work, and if the care be taken that the machine is not working at an improper speed either above or below its most efficient range then the efficiency need not be worse and may be better than that of a shunt-wound machine.

The use of a series-wound motor for a very large proportion of industrial operations does not appear to present any serious difficulty. It is, perhaps, not very generally recognised that the working efficiency of nearly all manufacturing machines is extremely low, so that the variation of load produced by change in the amount of work done by the machine is much less important than would at first sight be anticipated; for example, a bank of sewing machines running light, *i.e.*, without stitching, absorbs very nearly as much power as when the machines are stitching. Printing machines, if they are in motion at all, absorb about the same power whether they are printing or not. Tools used in engineering manufacture are not more efficient than those used in other industries. The insertion of the tool into the work in a turning lathe produces a surprisingly small variation in the current required to drive the lathe. The same is true to an even greater extent in the case of planing machines, and to a less extent in the case of milling machines.

It is easy to design a series motor so as to give a variation of power which is amply sufficient to cover the fluctuations arising from variations in work done by the machine, and to maintain the speed within a range of variation similar to that which occurs in all belt-driven machinery; and this can be done with a very slight variation in the efficiency of the motor. The necessarily high resistance of motors of the size under consideration, and their relatively low efficiency even under the best conditions, put practically out of account any risk of damage from the motor running away when lightly loaded. Many starting switches are now in use with magnetic devices for cutting off the supply when the current falls below a desired minimum or rises above a desired maximum, and there need be no fear of damage on this score.

The insurance companies are beginning to take an interest in the subject of electric driving, and care must be taken by engineers and all concerned that they are not allowed to impose absurd restrictions such as have so much hindered the proper development of electric wiring arrangements. In Glasgow, so far, there is not much of which to complain, but already proposals have been made by insurance companies which tend to injuriously affect the convenience and efficiency of electric motor arrangements. The best way to deal with the companies in such matters is, while treating them confidentially in the way of explaining what are the real dangers, and how they ought to be avoided, and giving them every encouragement to insist upon good workmanship, to be perfectly firm in refusing to adopt any absurd measures, such, for example, as placing motors on insulated non-combustible bases. The indications are that the enclosed motor is likely to be largely adopted in preference to the open-type machine, and, on the whole, this is quite a defensible preference, but it must not be forgotten that the enclosed motor is a less efficient machine than the open motor.

The starting switch is a much more probable source of danger, and, in fact, much yet remains to be done from the designers' and manufacturers' standpoint to make the starting switch even for small motors a thoroughly satisfactory article. The liquid switches largely employed in connection with some of the electric lighting stations seem, on the whole, to give satisfactory results; but the arrangement is more cumbrous and expensive than it ought to be, and is too liable to get out of repair from corrosion or to become ineffective from evaporation of the liquid. The American types of wire-starting switches, which have been largely imported into this country, are not satisfactory, and, in fact, the problem is still an open and unsolved one.

The enlightened policy now being followed by the Glasgow Corporation electrical engineer is likely to result in a very large demand for motors, and it would appear that there is here a more interesting

* Paper read before the Glasgow Section of the Institution of Electrical Engineers, April 27th.

Digitized by Google

and productive field of enterprise for the electrical engineer, as distinguished from the wireman, whose reputation is as good and his character no better than it ought to be.

There are a thousand interesting problems awaiting solution at the hands of electrical engineers for the application of electric power to all departments of industry, and there is now no lack of interest on the part of the public, so that an intelligent and skilful application to the problem will certainly result in profit to those engineers who have the ability to solve it.

DISCUSSION.

Mr. HIRD entered into an explanation of some curves shown by Mr. Mavor during the reading of his Paper. These had been plotted from results obtained, partly experimental and partly by calculation, from a smaller motor, wound successively as a shunt and as a series machine.

Mr. WM. A. CHAMEN could not quite follow the results shown by Mr. Mavor, as in some cases they seemed to point to the fact that series-wound motors were superior to shunt-wound motors; he always thought that series motors were the thing for sudden bursts of load, but from the diagrams shown it seemed that shunt motors would be far better for this than the series. A more interesting item to him personally was the question of switching a motor on and off a circuit, and it was a point that did not seem to get proper attention, or else very elaborate, and to his thinking, unnecessary devices were used. A very simple arrangement had been used by him for a long time with very satisfactory results. The first movement of the switch handle immediately put the full pressure on to the exciting circuit, the armature circuit being closed only through a resistance which was cut out step by step by further movement of the handle till the armature got the full pressure. In the same way in breaking the motor current, the full pressure was kept across the field circuit till the current in the armature circuit had been reduced to a minimum, and the importance of this latter point he insisted upon, viz., that the shunt circuit should be kept fully excited till the armature circuit was open. He further pointed out that with a shunt-wound motor an automatic cut-out switch was essential, as the motor might often be so situated that the supply might be stopped for a time and then resumed, in which case, if the motor was left in circuit, serious damage would probably result.

After a few remarks by Prof. GRAY,

Mr. McWHIRTER endorsed Mr. Mavor's opinion that the question of the advantages of the use of a shunt or a series motor was all a question of experience. Mr. Mavor's remarks with reference to the inefficiency of engineering tools must, he said, have appealed to all who have had to do with such work. The use to which the motor was to be put seemed to him to limit the use of series motors, as, for instance, in the case of sewing machines; the speed might with a series motor be doubled or even trebled with very serious consequences. His son had designed a switch on the same lines as that mentioned by Mr. Chamen for use with hydraulic work.

Mr. COATES said that the fact should not be lost sight of that with some machines which motors were called upon to drive there was a very great difference between light and full load, and he instanced such tools as hay cutters and oat crushers.

Prof. WATKINSON said that series motors were only suitable when the load was constant, as the speed was not so easily regulated. With regard to the question of variable speed and constant power, there were lots of people who claimed to have solved this problem, but, he believed, only with indifferent results; he understood, however, that Mr. Ferranti had recently designed a motor to effect this purpose.

Mr. STUART thought that the question of varying-speed and constant-load motors was purely one of design.

Mr. MAVOR, in reply, said that he would like to make one addition to Mr. Chamen's switch—viz., a few lamps across the shunt. As regarded Mr. Coates' reference to hay-cutters and similar tools, there were, of course, some which were very efficient indeed, notably, for instance, the circular saw. Mr. Tidd, without getting up, had mentioned to him the punching machine, and he would like to point out a very interesting point in connection with this tool, a point probably that few even of those present realised—viz., that a very small motor, even a ½ H.P., would be sufficient to drive a large punching machine, provided only that a sufficiently heavy flywheel was fitted.

CORRESPONDENCE.

LONG DISTANCE TRANSMISSION OF POWER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: What have I done that I should be pilloried by being dragged into a holiday discussion between two professors? I never said you could transmit below 50 per cent., and I never read Prof. Perry's 1886 Paper, and have no notion of the truths of which it reeks. I have known for a long time, however, that the efficiency of a system with a constant pressure at the generating end goes up with the receiving pressure until it equals the generator pressure, and that the intake of the motor goes up until its pressure is half that of the generator. From this it is clear that you can always get at least 50 per cent., even if you have to put down gold conductors, but Prof. Perry stated that you cannot get less than 50 per cent. No doubt he meant that no one would be such a fool as to take less, which is not quite the same thing. It may be true—I do not know—I am not a foolometer. If Prof. Perry cannot convince me of the truth of his statements by elementary algebra, it is probably not the fault of his algebra, but of the looseness of his statements.

In the discussion on Prof. Forbes' Paper I said nothing contradicting Prof. Perry's efficiency statement; as far as I remember, I found fault with calculations as to conductors based on false assumptions. Insulation and other matters complicate the cost of high pressure cables so that the ordinary calculations based only on the cost of copper per ton often lead to untrue results. I have frequently attacked mathematiculists for falsifying data in order to air their mathematics. In electrical engineering this vice is very prevalent. Fully two-thirds of the mathematical writing in the electrical press is waste paper, not because the mathematics are faulty, but because the data or assumptions are wrong. Of course it is an easy but an unfair reply to insinuate that I know no mathematics, or that I dislike mathematics, and that I cannot understand a simple thing because it involves elementary algebra. Prof. Perry knows as well as I do that that is no answer, and that when I object to the doings of the electrical mathematiculists it is because their data are twisted to make their mathematics possible, and because a display of mathematical symbols impresses the ignorant, and such work gets credit which it in no way deserves.

First-rate scientific work often demands mathematics of a high order, but it is a vulgar error to credit the value to the mathematics, and to suppose a Paper is valuable because it is mathematical. As a matter of fact, most of the electrical mathematical writing is done not by good mathematicians like Prof. Perry, but by mathematiculists with an elementary equipment. Most of the alternating-current hypothetics that fill the electrotechnical press involve nothing more than analytical trigonometry, and it is easier to work out such problems oneself than to follow the mathematiculist through mazes of, often, roundabout calculations. But as long as people like Prof. Perry prostitute their mathematical knowledge by working out false economy formulæ for conductors, and adding ignorance to the industry under the guise of science, the smaller fry may be deceived into thinking a Paper is good because it looks mathematical. The mathematiculist, and, indeed, the professor, is also under another misapprehension. He thinks that he alone can make calculations, and that the practical man is full of data from which he is unable, owing to his mathematical and scientific ignorance, to deduce anything. He therefore, data being cheap, and one lot being as good as another, assumes data that admit of mathematicules, and patronisingly presents the practical man with reams of matter which nobody reads, and which is very expensive to print. It enhances the mathematiculists' reputation, no doubt, but that is an evil. It ought to be generally realised that there is no bar to a practical man being scientific or mathematical, or both, if he likes, and that it is quite possible he knows what problems he wants to solve, and how to solve them, and also that he does so, and does not write Papers with full length calculations every time.

"Any ass can make mathematical calculations, but it takes a wise man to state a problem correctly."—*Ancient Eastern Proverb.*—Yours, &c.,

JAMES SWINBURNE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I think that if Prof. Perry's case were stated rather differently Prof. Forbes might be found ready to admit his argument. Assuming the instance quoted by Prof. Perry, of a motor working at one end of a line having 3 ohms resistance, with 1,000 volts at the generator end, taking 200 amperes and running at 400 terminal volts, with efficiency 40 per cent. The same motor, if geared to its work with gear ratio 2 to 3, would take 133 amperes and run at 600 terminal volts, efficiency 60 per cent., same mechanical output as before. The same result could be obtained without gearing if the motor were wound with 50 per cent. more turns on the armature, or if any equivalent alteration were made.

In general, if a motor is found running at the end of a transmission line with less than 50 per cent. efficiency, it

Digitized by Google

shows that the plant is not properly designed, since the same output can always be obtained with a higher efficiency than 50 per cent., the sum of the two efficiencies being 100.—Yours, &c., CHAS. A. CARUS-WILSON.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Prof. Forbes seems anxious for the dignity of the Institution of Electrical Engineers. He did not show much anxiety in this direction when he prepared his Paper; when in reading it he informed us that he disclaimed all idea of teaching the members anything about their profession; when he declared the uselessness of describing systems of which he had no personal knowledge, and then described six such systems,—with one other, of which he had had no personal knowledge for more than five years; when he repeatedly and loudly informed the meeting that the President-Elect had no knowledge of what he was talking about. And when I, using the very mildest words at my command, have ventured to say that my remarks were really correct and not wrong, Prof. Forbes pretends that the President of the Institution has no right to defend himself. Prof. Forbes is justified by past experience in assuming that men of position prefer not to answer him, but I have duty to consider, and not mere preference. Sir, I affirm that on all occasions everywhere I have refrained from exercising the full force of my arguments when, by doing so, I could avoid a quarrel. I cannot think it possible that there is a single instance of my having provoked a quarrel when it was possible to avoid one without failing in duty.

There has been too much bad mathematics published about electrical engineering. There are many tables which purport to be correct and useful, and they are quite wrong. Surely if I know that all the numbers examined by me in the tables recently published by Prof. Forbes are quite wrong, it is my duty to say so, and that my duty is made clearer when he asserts after two warnings that they are quite right, because they have been computed by four computers. His remark (1) proves my surmise to be quite true. With a given conductor and generator we can transmit 1 H.P. with a minimum or with a maximum economy; he deliberately chooses the most wasteful method, and of course gets a very low efficiency. When I said that less than 50 per cent. efficiency was impossible, I made it clear that I meant that it was impossible for a competent electrical engineer. Anybody can waste energy unnecessarily, but to a competent electrical engineer it would be impossible in a scheme of power transmission.

In his remark (2), Prof. Forbes is quite right: I really did not dream that he was using his copper so very uneconomically. I did not dream that he would use nearly three-quarters of all his copper in his first section of 50 miles. But in spite of this, taking his copper exactly as he arranges it, if he started wasting 7·27 H.P. and transforming 2·53 H.P. in his boosters to give up 1 H.P. at the distance of 100 miles, then I say that, unless he employed an artificial method of preventing economy, he would presently find that he was giving up 1 H.P. at the distance of 100 miles wasting only 0·784 H.P. and transforming only 0·517 H.P. in his boosters. Instead of an electrical efficiency of 12 per cent., he would have one of 56 per cent. The examination of column 2 of the foregoing table will make this clear to anybody.

If, however, he would allow me to re-arrange his copper without altering the amount—if he would even allow me to use the same size of conductor throughout, and equal lengths in the two sections—I would give him very much greater economy, or 72·6 per cent., instead of his 12 per cent., although these conditions are not the best.

Why, Sir, even if he takes only one section of 100 miles, and boosts at the end he will get 62·8 per cent. efficiency.

There is not one case that I have examined in which I cannot get as good electrical economy as is specified by Prof. Forbes with only a fraction of the amount of copper which he specifies.—Yours, &c., JOHN PERRY.

June 13.

Per Horse-Power Delivered.

—	According to Prof. Forbes.	Correct figures	Conductor everywhere of same cr'ss-section: Two equal lengths.	One section only. One booster only.

ELECTRIC TRACTION UNDER BRITISH CONDITIONS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have to accord you my thanks for having made my recent Paper a text for a leader in *The Electrician*. At the same time, however, I must point out that what you call my "most vital position" is neither stated in nor to be inferred from the Paper.

The subject which I discussed is the "Calculation of Distributing Systems," and the questions of the best system of generation was not touched upon. Therefore you will not find in the Paper any deductions as to the relative merits of the various systems of generation. What I tried to show is: that it is possible to calculate conductor systems, and the cost of distribution upon general principles, and I applied those principles to a given case as an example. The cost of generation was taken as a constant and identical in each of the three arrangements suggested. I pointed out that the results show what saving has to be made by generating the energy at a single station (whether on the line or at a distance) to overbalance the increased cost of distribution. I claim that this method of treating the matter is the best and most practical way of approaching the consideration of the best means of supplying power to a particular system of tramways or light railways.

Estimates of the cost of generation are much more complicated, and must be made with regard to local conditions of such a various character and so numerous that every case needs the careful study of an experienced man.

The simpler calculation will often narrow the scope and abridge the length of the more complex estimate.

I am certainly not a "polyphase engineer," nor a "continuous," "high" or "low" tension engineer, but with an open mind, I hope, am anxious to use any method at hand which will give the best results in each case.

The supply of electrical energy to a whole county, and the question whether such supply in bulk is likely to prove more advantageous to all concerned than supply to smaller districts from many stations, are questions of a quite different character, and involving data of far greater complexity than the subject I discussed. They are, as you point out, under the consideration of more august bodies than those to whom my modest remarks appeal.

It is incontestable, however, that so long as we are confined to the direct-current motor for electric traction upon streets and highways, polyphase supply systems are very

Digitized by Google

heavily handicapped, and can only be properly adopted where there is clear evidence that the generating costs will be greatly lessened by the centralised power production. The system of calculation I have discussed will show "how much" such saving in generating costs must be in each case.—Yours, &c.,

HENRY M. SAYERS.

London, S.E., June 11.

THE ARTIFICIAL PRODUCTION OF DIAMONDS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In the *Anglo-American Magazine* for January last, and in a now defunct English illustrated paper issued in the same month, there appeared Papers on the above and other subjects from the pen of a Mr. "Hudson" Maxim, claiming for himself, amongst other things, the merit of being the inventor of an electrical process of manufacturing diamonds. May I ask you to give me space in your journal to say (1) that this Mr. "Hudson" Maxim must not be confounded with Mr. Hiram Stevens Maxim, whose inventions and discoveries have done very much to benefit the whole world. As a matter of fact, this Mr. "Hudson" Maxim's real christian name is Isaac, and he is a brother of the man whose inventions he is so anxious to father.

In particular, Isaac claims to have applied for a patent in 1895 for an electrical process for making artificial diamonds, and makes the "startling" announcement that if a carbon rod is electrically heated in an atmosphere of hydro-carbon vapours, the carbon will be deposited upon the hottest part of the rod. Now, as is well known, Mr. Hiram S. Maxim's historical electric lamp patent, registered in the United States Patent Office on Oct. 4, 1878, was the first patent filed in any country for the deposition of carbon on electrically-heated rods,* and consequently Isaac Maxim's claim to be the inventor falls to the ground; and the same may be said for the remainder of his claims, which include high explosives and special forms of guns, with both of which subjects Mr. H. S. Maxim's name has been associated for the past quarter of a century. It ought to be added that the patent applied for in 1895 in the name of "Hudson" Maxim was rejected.

I may say that Mr. Hiram S. Maxim's patent, lodged in 1878, underwent many alterations before it was finally issued as Patent No. 230,958 on Aug. 10, 1880. So far back as 1881 Mr. H. S. Maxim showed specimens of deposited carbon to Profs. J. and H. Draper, Barker, Vanderwyde and others.

In the course of a communication I have recently received from Mr. Hiram S. Maxim he writes:—

In 1888, Isaac Maxim came to my house at Crayford and spent six months, and went home at the beginning of 1889. While he was with me I told him of my carbon experiment, and I told him that Prof. John Draper had said that I had come nearer to the production of artificial diamonds than any man living. In 1895 or 1896, or somewhere about those dates, Isaac was again in England, and I was told by him that he had thought a good deal of what I had said to him on the deposition of diamonds, and that he had applied for a patent in the States for making them on the process I had described, and that the patent had been rejected on the ground of my earlier application. It was in September, 1897, that I again took up the question, and, as all my experiments formerly had been done with low pressures, I determined to experiment with high pressure; but, of course, a high pressure of hydro-carbon gases would not do at all, on account of the rapid and smutty deposit. It occurred to me that I might get new results which might be advantageously used in making my new compound filaments if I heated carbon extremely hot under a very high pressure, and in order to get this pressure I filled the apparatus with carbonic acid gas and gasoline. Now, when the electrical current—that is, the voltaic arc—is brought into action in the presence of these materials the carbon dioxide is converted into carbon mon-oxide, and the result is an extremely high pressure, which need not be so rich in hydro-carbon vapours as to produce a rapid and smutty deposit. This was the first patent ever taken out for producing high pressures without a superabundance of hydro-carbon vapours, the first time that a slow deposit was obtained under a high pressure. My recent patent was for the means of obtaining high pressures and the apparatus employed therefor.

I purchased the breech end of an old gun, and when the apparatus was thoroughly under way I called on Isaac Maxim, who had been experimenting with a view of making calcic carbide. The process had been a dead failure, and I knew that the same current could be obtained. I told him that I had got the breech end of a gun which I was making into an apparatus, but I did not tell him how I was going to obtain high pressure. A few hours later* I saw a flaming account of my apparatus of the breech end of an old gun; and a lot of nonsense about high pressures, electrical deposits, and so forth. However, as I had said nothing about how the high pressures were obtained, he was unable to give any part of the show away. To speak of a pressure without saying what it is, discloses nothing and means less. I knew Isaac could not apply for a patent, but he did the next thing to it. He tried to make the process public.

If you can find space for this letter I shall be glad.—Yours, &c.,

W. G. C.

London, June 11, 1900.

* The following is a quotation from the specification: "Upon heating of the carbon by the passage of the current, its great heat decomposes the gasoline vapours immediately contiguous to it, and precipitates a slight coating of carbon taken from it upon the hottest part of the incandescent conductor, which is thus slightly increased in size at its weakest points."

As far back as 1885, in "'The Electrician' Electrical Trades' Directory and Handbook" (published in January, 1885), in the biographical sketch of Mr. H. S. Maxim there appears the following sentence: "At this time Maxim expressed to Mr. Shuyler—with whom he had made an arrangement for electrical experiments—his opinion that the carbon of lamps does not become fused or volatilised, but simply oxidised, by the atmosphere or by some combination of the oxygen in the lamp. To prove that oxygen is the sole destructive agent he made a lamp from which he expelled the air, introducing gasoline vapour in its place, when he found that the carbon, instead of wearing away, gained in weight and volume, while assuming a grey metallic colour."

A MOTOR-TESTING CRADLE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: My attention has been called to a passage in Prof. Fleming's excellent "Electrical Laboratory Notes," in which (No. 17 Elementary) a motor test is made by balancing the motor on what is there called a "Brackett" cradle, that is a cradle devised and used by Prof. Brackett, of the College of New Jersey, America. May I be allowed to correct the date of the cradle method, which has turned out to be both accurate and easy to use. In a correspondence with the Professor, he states "There have been no Papers published by myself concerning the cradle other than the simple descriptions which have appeared in *The Electrician* and other publications of a similar character." I find that the earliest account of the Brackett method is given in *The Electrician*, Vol. XIII., p. 80, June 7, 1884. In 1882 I devised exactly the same method, and an account of it was given at the University College, Bristol, in 1883, and the apparatus and the method are described with one diagram in the *Proceedings* of the Bristol Naturalists Society, November, 1883.—Yours, &c.,

Oxford, June 6. F. J. JERVIS-SMITH.

[Mr. Jervis-Smith encloses a photograph of the machine which was in constant use in 1882 in his laboratory at Taunton.—ED. *E.*]

PARLIAMENTARY INTELLIGENCE.

ROCHDALE TRAMWAYS.

The Rochdale Corporation Bill was considered by the Police and Sanitary Regulations committee of the House of Commons yesterday, Lord E. Fitzmaurice presiding. The bill proposes, among other matters, to authorise the Corporation to reconstruct the tramway system and to work it by electric traction, and to make extensions in the adjoining districts of Heywood, Castleton, Whitworth and Morden.

Mr. HARPER, for the Corporation, stated that the statutory term of the existing companies, which was incorporated in 1881, was about to expire, and the Corporation had decided to acquire the lines, and to work them. With the proposed extensions there would be over 12 miles of single line, and about 5½ miles of double line. The tramways were at present on the 3ft. 6in. gauge, and it was proposed to re-construct them to the standard gauge The amount proposed to be borrowed was £400,000, of which £145,000 was for tramway construction and £71,400 for street works. When the lines were re-laid on the wider gauge they would be able to work the system homogeneously with the tramways of the surrounding districts and provide a through service to Bury and Manchester.

Mr. J. Kincaid (Messrs. Kincaid, Waller and Manville), electrical adviser to the Corporation, spoke as to the desirability of the proposed scheme, and the Mayor of Rochdale (Mr. Cunliffe), and the chairmen of the Councils whose jurisdiction would be entered by the Rochdale tramways supported the bill.

The Committee passed the tramways and streets improvements portion of the bill.

* The *Pall Mall Gazette* for Sept. 8, 1897.

LEGAL INTELLIGENCE.

Electric Construction Co. (Ltd.) v. Imperial Tramways Co. (Ltd.) and British Thomson-Houston Co. (Ltd.) (third parties).

In the Court of Appeal (the Master of the Rolls and Lord Justices Rigby and Collins), yesterday (Thursday), the appeal was heard of plaintiffs from the judgment for the defendants of Mr. Justice Cozens-Hardy on Nov. 14 last. The action was for an injunction to restrain defendants from infringing letters patent (No. 9,527, 1885) granted to T. J. Handford, of which plaintiffs were the holders. The infringement complained of was the use of electric motors supplied by defendants on the Middlesbrough, Stockton, and Thornaby tramways. The British Thomson-Houston Co. were added as third parties, but were treated as defendants. The patent sued upon having expired, plaintiffs asked for damages in lieu of injunction. The pleaded defences were a denial of infringement and an allegation that plaintiffs' patent was invalid. Defendants also said there was no subject-matter in the invention. The case was fully reported in *The Electrician* of Nov. 10 and 17, 1899.

Mr. FLETCHER MOULTON, Q.C., for appellants, said in this case infringement was admitted. The allegation of invalidity was based on the usual objections—anticipation and no subject-matter being the chief ones. But the point on which the judge decided against the validity of the patent was one of construction—construction of one of the claims of the specification itself. That being so, he proposed to take their lordships at once to the specification, because he should submit that the interpretation put upon it by the learned judge could not be sustained.

The MASTER OF THE ROLLS: Do you admit if the learned judge's construction of the impeached claim is right, there was no anticipation?

Mr. MOULTON: There is a later question, which arises in this way: We say the claim is so limited that even upon the learned judge's construction there would not be anticipation. In order to assist their lordships to understand the specification, he would shortly explain what the nature of the invention was. It applied to the question of how to mount an electric motor on the car which it drove. Of course, the first peculiarity of an electric motor was that it was purely rotatory, and the next was that many parts of it must be exceedingly massive. It was a machine which ought not to be subjected to violent jolts, because the work was very delicate, in order to sustain perfect insulation of the wire both on the fixed and the moving parts. The only part of a motor which moved was the armature, which rotated inside the field-magnets. In order to have effectiveness it must revolve quite close to the field-magnets, because the intensity of magnetism diminished very rapidly as the surface of the magnets was left. It was absolutely essential that the motor should be fixed in its place. The bearings could not be allowed to move at all relatively to the motor, and the motor must not be subjected to shocks. The idea for using motors for cars was first started in 1880, or even earlier. He thought the Master of the Rolls would remember seeing in the Exhibition of 1881, at Paris, a car by Siemens, driven by a motor. Several methods of mounting the motor on the car were tried, and in 1885 the present inventor, Mr. Frank Julian Sprague, invented this method, which now in the vast stride of electric traction had become the universal one. What the inventor did was this: He sleeved the field-magnets of the motor on one of the axles and supported the other end by means of springs. The consequence was that by sleeving one end if there was a jolt on the wheel it was not a dead jolt of the whole of the weight of the motor, as it would have been if the centre of gravity of the motor had been above the wheel. This had the effect of causing a kind of rotation which would take off a great deal of the severe jolt, and the movement of the truck only communicated itself to the motor through the supporting springs. The two features of the invention were the sleeving of one end on to an axle and having spring supports at the other end. This enabled the inventor not only to avoid jolts, but also enabled him to reduce the speed of rotation from the motor to the wheel. Effective motors, unless they were very big, moved rapidly, having a large number of revolutions per minute. It was not practicable to make the wheel of the car go as fast as that. It was necessary to gear down so that several revolutions of the motor corresponded to one revolution of the wheel. The sleeving at one end made the gearing accurate in spite of the jolts. One thing was that no jolting would throw your gear out of gear, and the other was, that the jolts were very much diminished. That was the nature of the invention. Having referred to the specification, Mr. Moulton said he should confidently submit that one thing was clear, that this was a spring-supported motor, characterised by being sleeved upon a driving axle and having one or two sets of springs to connect it either with the truck, or with the carriage body if there was no truck. That was the invention which they were prepared to defend, and which they insisted was the invention described. Now the learned judge in the court below had taken what he should contend was quite a wrong view of the case. Taking that part of the specification, he said, "D is the field magnet of an electro-dynamic motor, and E the armature thereof. The yoke or back piece of the field-magnet is hung from a cross piece of the truck by heavy springs or from the car body itself in case of a street car or other vehicle having no truck," the learned judge had found that that meant was hung not by springs in the case of a car which had no truck. He (Mr. Moulton) failed to see absolutely any justification in the language of the specification for such a view as that.

The MASTER OF THE ROLLS: You say springs are essential in both cases?

Mr. MOULTON: Certainly that was the whole spirit of the invention. He must say there was a disputed interpretation of claim 1 as to whether it included springs or not. The claim was for the "motor of an electric railway car or carriage having its field-magnet centred or sleeved upon a driving axle, its armature supported directly upon the said field magnet, and having a shaft separate from the driving axle and gearing communicating motion from the armature shaft to the driving axle, substantially as hereinbefore described," but reading the specification from beginning to end it was plain that the inventor relied upon springs.

The MASTER OF THE ROLLS: Your point is that springs are essential, and that the only things optional are relieving or supporting springs.

Mr. MOULTON said it was so, but the learned judge had said that was not so. That where there was a car body and no truck there was suspension without springs. But really the truck and the car body without the truck were mechanically the same. The car body might not be called a truck, but it was the same thing.

Mr. Justice RIGBY: It is rather peculiar that the inventor never used the word springs in connection with the car body.

Mr. MOULTON: Oh, yes, he does. He says: "These springs extend to cross bars on the truck frame, or to the car body in case no truck is used." The "or" is "or" to, and not "or" by. There is no possible conceivable reason why he should not have spring suspension in both cases, and it is only a too abundant caution that makes him refer as a practical man to the case of a car body without a truck.

Lord Justice RIGBY: I think the meaning might have been made more clear by a little alteration of the language of the specification.

Mr. MOULTON: The claims I shall submit describe nothing but a spring attachment. The second claim brings in the relieving or optional springs, and I do not think I need trouble much about that.

The MASTER OF THE ROLLS: The serious question seems to be claims 1 and 3.

Mr. MOULTON said that with regard to claim 1, although no express mention was made of it, it implied spring supports. Supposing for an instant they intended suing a man who bolted his dynamo to the truck, and said to him, "You have got everything mentioned in claim 1," did anyone suppose for a minute that the Court would not say, "What! Is that substantially as hereinbefore described?"

Lord Justice RIGBY: What is the difference between claims 1 and 3.

Mr. MOULTON: The difference is two-fold. In the first place, claim 1 is limited by the phrase, "having the armature directly supported on the field-magnets." Then there was a difference in the point of view. Claim 3 is drafted in a totally different way to 1 and 2. 1 and 2 go through the specification, but claim 3 seizes the spirit of the thing. I did not want to get off the safe ground of what my invention is: I say my invention never contemplated anything but spring suspension, and that is reiterated all through the specification. The whole connection is through springs. I dare say that the claims might cover a good deal of latitude as to the way in which the springs are to be applied, but I would not include cases where the motor was bolted to the truck or the car body. That was never contemplated, and, indeed, it was the whole aim of the invention to obviate that. I quite agree with the learned judge that claim No. 2 is claim No. 1 plus the optional springs, but both imply the spring supports or the equivalent to spring supports.

Lord Justice RIGBY: What would be the equivalent to spring supports?

Mr. MOULTON: I do not know of any equivalent. A case has been suggested of a motor suspended by links to something having springs on either side, and that *de facto* would, of course, be spring supported. The only question really is, however, whether the inventor meant to tell the public that he claimed fixing the motor by any other method than that of springs.

The MASTER OF THE ROLLS: We shall have to consider whether he has warned the public off a wider field in his own interests.

Mr. MOULTON: If spring suspension had been found in claims 1 and 2, the inventor would still have added claim 3, because it is a wider claim.

The MASTER OF THE ROLLS: I must say I do not think, on looking into it, that claim 2 refers only to relieving springs, and if that is so it is seriously against you.

Mr. MOULTON: I shall submit it refers to relieving springs only Else of what value would be "substantially as hereinbefore described?"

The MASTER OF THE ROLLS: Those words cover a multitude of sins.

Mr. MOULTON: It is not necessary to read in the words "spring supports" if it is understood, as any one would understand it, that the spring connections with the truck is essential.

The hearing was then adjourned.

River Plate Electric Light and Traction Co. (Ltd.).

On Wednesday Messrs. Glyn, Mills, Currie & Co., petitioned Mr. Justice Wright for the compulsory winding up of this company. Counsel for the company stated there was a scheme of reconstruction in hand under which the creditors would be paid in full. The hearing was therefore postponed until 20th inst.

Appleford v. Charing Cross and Strand Electricity Supply Corporation (Ltd.).

This case was down for hearing before Mr. Justice Kekewich on Wednesday, but was ordered to stand over as the parties were likely to come to terms.

"Workshop" v. "Workplace."

At the Guildhall (London) Police Court, on Tuesday, Mr. W. Brass, the owner of a building in Threadneedle-street, E.C., in which persons of both sexes are employed, was summoned for failing to comply with an official notice to make certain alterations in accordance with the Public Health (London) Act, 1891. It appeared that the lessees of the third and fourth floors of the building employed a number of female typists, and the questions to be decided by the magistrate were whether this

Digitized by Google

was a "workplace." It was stated that although a "workshop" had been defined there had been no definition of "workplace." The complaint was that the sanitary arrangements on the premises were not only inadequate, but were provided for the use of all persons without distinction of sex. It was contended, for the defence, that the room used by the female typists was not, under the Act, a "workplace," and that if the Act were so construed, it would affect every office where females were employed. Particularly, it was contended, that premises where lady telegraph clerks were employed had been held not to constitute a "workplace" under the Act, and, by implication, it may be assumed that where lady telephone operators are employed the law would similarly hold.

Mr. VICKERY, who prosecuted on behalf of the City of London Corporation, said the question before the Court had never been fought out before. He contended that these young ladies, being mere "mechanical machines" the place where they were employed was a "workplace" under the Act.

Mr. Ald. ALLISTON, who tried the case, said the question was a most important one, but he must hold that the premises in Threadneedle-street, used as described, did not come within the meaning of sec. 38 of the Public Health (London) Act, and the summons must be dismissed.

FORTHCOMING LEGAL CAUSES.

List of cases with an electrical interest entered for trial at the Royal Courts of Justice, London, during the Trinity Sittings :—

COURT OF APPEAL (CHANCERY DIVISION). *General Appeals.*

Electric Construction Co. (Ltd.) *v.* Imperial Tramways Co. (Ltd.). (British Thomson-Houston Co. (Ltd.) third parties). Appeal of plaintiffs from order of Mr. Justice Cozens-Hardy, dated Nov. 14, 1899.

Rucker *v.* The London Electric Corporation (Ltd.). Appeal of plaintiff from order of Mr. Justice Farwell, dated February 12, 1900.

Hawkes *v.* Leyton Urban District Council. Appeal of defendants from order of Mr. Justice Buckley, dated February 28, 1900.

City of London Electric Lighting Co. *v.* Mayor and Corporation of London. Appeal of defendants from order of Mr. Justice Farwell, dated May 3, 1900.

Attorney-General *v.* London County Council. Appeal of defendants from order of Mr. Justice Cozens-Hardy, dated March 19, 1900.

QUEEN'S BENCH APPEALS. (*Final list.*)

Borough of Hyde *v.* Oldham, Ashton and Hyde Electric Tramway, (Ltd.). Appeal of defendants from judgment of Mr. Justice Grantham, dated July 3, 1899.

HIGH COURT OF JUSTICE.—CHANCERY DIVISION.

Before Mr. Justice Byrne.

Isle of Thanet Electric Trams, &c., Co. *v.* Abbott. Cause for trial without witnesses.

QUEEN'S BENCH DIVISION.—*Special Juries.*

Hampstead Electric Supply Co. (Ltd.) *v.* Bromwich and another (bill).

Fell *v.* British Electric Traction Co. (Ltd.). (Money paid.)

Common Juries.

Evered *v.* Electrical Undertakings (Ltd.). (Wrongful dismissal.)

MUNICIPAL, FOREIGN & GENERAL NOTES.

Aldershot.—The Board of Trade has intimated that the consideration of the question of revoking the Aldershot electric lighting order for a further period of twelve months from Aug. 12 has been deferred. The Council has already decided to establish municipal electricity works, and are seeking a suitable site.

Argentina.—Mr. F. Scharrer, who holds an electric lighting concession from the Rosario municipality, has acquired land for the erection of electricity works.

Bahia Blanca municipality has declared as lapsed the electric lighting and tramway concession granted to Mr. C. Thursby.

Asylum Lighting.—The question of electric lighting will come before the Poplar and Stepney (London) Sick Asylum Board at an early date.

Ayr.—A report was submitted to the Council on Monday by the burgh electrical engineer, recommending the changing of the system of electricity supply in the centre of the town from low-tension alternating current to low-tension three-wire continuous current distribution. The estimated cost of the alteration was £8,730. Consideration of the matter has been postponed.

Barnes.—The District Council are about to invite tenders for condensing plant and an overhead travelling crane for the electricity works.

Blackpool.—At the meeting of the Town Council, on Tuesday, the chairman of the Tramways committee (Ald. Brodie) announced that during the Whitsuntide ten days they had taken £2,159, an increase of £706 compared with last year, and had carried 327,594 passengers, an increase of 148,496 on the previous year, whilst the mileage run was 16,459, being 6,509 over last year. The new Claremont Park line meant an increase of 50 per cent. on the profits.

Bohmisch-Kamnitz (Austria).—The Austrian Schuckert Co. has secured a contract for erecting central electricity works in this town.

Bradford.—The salary of the manager of the electric tramways (Mr. C. J. Spencer) has been increased from £200 to £300 per annum from June 1, with an annual increase of £100 until a maximum of £500 per annum is reached, on condition that Mr. Spencer enters into an agreement to remain in the service of the Corporation during the next five years.

Burton-on-Trent.—The accounts of the Electricity department for the year ended March, 1900, have been issued, and show very satisfactory progress. The total number of units sold was 154,290, compared with 118,145 in 1899 ; and the average price per unit was 5·45d., against 5·57d. in 1899. Expenditure (including interest and sinking fund) exceeded income by £5. 9s. 6d. In the previous year the adverse balance was £769. 16s. 2d.

Central London Railway.—The opening of this line has been fixed for 27th inst. by His Royal Highness the Prince of Wales.

Cheltenham.—Application has been made for sanction to borrow £790 further for electric lighting.

Chester.—The accounts of the electricity department for the year ended March 25 have been issued. Generation, distribution, and management expenses, &c., amount to £4,607. 18s. 7d., and gross receipts from public and private lighting, meter rentals, &c., to £9,628. 3s. 10d., leaving a balance of £4,932. 13s. 11d., out of which interest (£1,889. 8s. 4d.) and sinking fund (£1,903. 5s. 7d.) have been paid, leaving net profit £1,140 to be carried to reserve. The total capital expenditure was £65,765. 13s. 3d., and sanction to borrow £65,000 of this sum has been received. 763,154 units of current were generated, of which 217,823 units were supplied to public lamps, and 399,969 to private consumers. There are 165 arcs and 206 incandescents used in the public lighting. The total maximum supply demanded was 529 kw.

Cycle Lights.—An interesting point was raised at the North London Police Court last week. A Mr. Thornton was summoned for riding on his bicycle on the night of May 28, and that he, instead of having the regulation lamp on his machine, wore a small electric button-hole lamp attached to his coat. A policeman pulled him up for not obeying the regulations to have a light attached to his bicycle. His reply was that he considered he had sufficient light to signal his approach, and, as he was a member of the National Cyclists' Union, the police might summon him. For the Union it was maintained that a great many cyclists who had been consulted were of opinion that there had been no evasion of the law. The police-constable admitted he saw the light at a distance, but thought it was a cigar. The magistrate (Mr. Bros) held that the light was not on the machine as required by law, and imposed a nominal penalty.

Dalkeith.—By arrangement with the Burgh Commissioners, Messrs. Crompton & Co. will apply for electric lighting powers for this district. The Commissioners' consulting engineer (Mr. A. A. Campbell Swinton) advised that Messrs. Crompton & Co.'s proposals were fair and reasonable. Current will be supplied at 3d. per unit for public lighting.

Death from Electric Shock.—An inquest was held this week at Wolverhampton into the deaths of Samuel Clulow and Daniel Trawford, who died on May 31 from the effects of an electric shock received at the Mars Ironworks, Ettingshall. Mr. C. F. Wright represented Messrs. George Adams and Sons (Ltd.), and Mr. J. S Sharpe and Mr. J. E. Ashworth the relatives of deceased.

Witness MEREDITH stated that on the night of May 31 he noticed Clulow lying on his back in the weighing cabin. His left hand was in contact with a wire used for raising and lowering an arc lamp. When witness went to his assistance his hand touched the wire, and he received a shock. It was necessary to pass the wire to enter the cabin, and witness had often touched it.

Witness JONES stated that he saw the two men lying in the cabin. He caught hold of Clulow, and received a shock which drew his arms up. In answer to Mr. Wright witness said he was in a perspiration. He took hold of Clulow by the trousers.

Witness FELTON deposed that Trawford was lying across Clulow. Dr. Bulger was sent for, but was not at home, and the men were taken to the Wolverhampton Hospital, where attempts were made to restore animation. He had received no complaint of anything wrong with the plant.

Mr. W. J. BAKER, electrical engineer, in the employ of Messrs. Adams and Sons, deposed to installing the electric light at the works in November last. The lamps were second-hand, and all the repairs he did himself. He could not explain how the current got down the wire touched by deceased. He had had no special electrical training, and what he knew he had learned from books and by serving with an electrical engineer. He had put in another installation, but he had no experience of so high a voltage as that at these works. It would have been better to have had porcelain insulators on the top of the lamps to which the pulley wire for raising them was attached instead of the wood blocks.

Mr. HY. LEA (Messrs. H. Lea and Son) consulting electrical engineer, Birmingham, who had made an inspection of the electrical plant at the works, was unable to state how the accident happened.

Mr. W. H. THORNBURY, consulting electrical engineer, Birmingham, said the wire was no part of the electrical system, and ought to have been completely isolated. He thought that at the time of the accident there was electrical connection between the lamp and the pulley-wire, which

Digitized by Google

thus became a "live" wire; and if there was a leakage of electricity to earth at a distant part of the system a man standing on the ground, and touching the pulley-wire, would receive a shock. When the tests were made no such leakage could be discovered, but he thought that at the time of the accident there was a leakage from another lamp through a suspension wire to the earth some distance away. It was customary to use wire for raising and lowering lamps, and some lamps were still made without a porcelain insulator. Some of the wires passed through brick walls, and were liable to have their insulating coating worn off by friction, though in this case there was no evidence of leakage from this cause. With regard to a statement that had been made that the installation was capable of carrying 25 arc lamps at 1,250 volts, and that at the time of the accident there was a current of 700 volts, witness said such a high voltage was not necessary in these works. There were safe systems by which arc lamps could be worked at low voltage, and he recommended that the plant be reconstructed. With the exception of the electrical connection between the lamp and the suspending wire there was nothing wrong with the plant.

Dr. T. W. LACHFORD, assistant house surgeon at the hospital, said the appearance of the bodies was consistent with death from electric shock.

The CORONER said he did not think anyone was to blame.

The jury found that deceased met their deaths from an electric shock, accidentally received, and recommended that a low-voltage system be introduced into the works, or that suspension wires should be out of reach.

Mr. WRIGHT said the suggestion made by the jury would have careful attention. He might add that the company would satisfy all claims for compensation.

Dessau (Germany)—The line of tramway in this town, which has until now been driven by gas motors, is to be converted to the overhead electric trolley system during the present summer, notwithstanding that the present line has attained a fair measure of success financially.

Doncaster.—The accounts for the first year's working of the electricity undertaking just issued show a deficit of nearly £1,000.

Dorking.—An offer by Edmundson's Electricity Corporation to take a transfer of the Council's provisional electric lighting order has been referred to the General Purposes Committee.

Dublin.—At the Corporation meeting on Monday, Mr. Jones said that since the change-over in the electric system their electrical business had been brought to perfection. The change had given every satisfaction, it was working in the best possible manner, and it had resulted in a very large and immediate increase of the business of the Corporation. The great improvement in the lighting was spoken to by Mr. Ald. Meade, the High Sheriff, and the Lord Mayor.

Eastbourne.—Several thoroughfares are to be lighted by arc lamps, and the question of the electric lighting of the whole of the streets is under the consideration of the Electric Lighting committee.

East Grinstead—Application is to be made for a provisional electric lighting order.

Eccles.—The Council have entered into an agreement with the promoters of the South Lancashire Tramway scheme, whereby the Council undertake to obtain powers to construct the portion of the tramways from the boundary of the township to the junction of the existing tramways at Peel Green.

The accounts of the Electric Lighting department for the past year show a deficit of £789, but of this £346 is for repayment of loans. The estimated loss on next year's working is £800. At the last Council meeting Ald. Kendall said he regarded the figures as satisfactory, considering the difficulties the Council had had to contend against. Ald. Spary suggested that the Electric Lighting committee should ascertain whether they could be supplied in bulk with electric current cheaper than the committee could generate it.

Edinburgh.—A sub-committee (Bailie Mackenze, Councillors Auldjo Jamieson, Sir Jas. Russell, Carmichael, Gibson, and Macpherson) has been appointed to consider the question of the provision for maintenance and renewal of the electric lighting plant.

Electrical Enterprise in Russia—In a recent report on the trade of the Kertch district, reference is made to a concession offered by the municipality for the electric lighting of the town and the construction and working of electric tramways. This scheme has so far not been carried out, as municipal contracts in Russia are seldom drawn up in such a manner as to induce British firms to tender. It is pointed out, however, that firms in a position to investigate the particulars and ascertain requirements on the spot often find that the apparent difficulties are easily overcome. The report concludes by appealing to commercial firms to send their representatives to Kertch to investigate the possibilities of the market, "for this is really a growing country."

The municipality of Mariupol have invited tenders for the construction of an electric tramway and the installation of the electric light. The tramway is to run through the principal thoroughfares, and to connect the town with the new port and extensive metallurgical works established in this district.

At Rostov-on-Don the conversion of the present horse tramways to electric traction is about to be commenced.

Electrically-Driven Dust-Cart Tenders.—The Public Health Department of the City of London Corporation recently advertised for tenders for the hire of an electrically-driven dust-cart. We learn that, although advertisements were inserted in all the journals likely to secure offers for these vehicles, not even an inquiry regarding these requirements was received. Mr. A. A. Voysey, the electrical engineer to the Corporation, in a communication to hand, writes:—

Possibly none of the people likely to take up such a matter have considered what excellent conditions a dust-cart service offers for the use of electricity.

Electric Tramways in Spain.—Up to March 31st last concessions for the following suburban electric tramways (as distinguished from those granted for inter-town traffic) have been awarded, and the majority of these are either working or in process of construction and equipment:—San Sebastian to Tolosa, Cadiz to San Fernando, Corunna to Burgos de Santiago, and Arriondas to Coradonga. The chief towns in Spain for which concessions for electric tramways have been granted are as follows:—Barcelona, Valencia, Seville, Saragosa, Corunna, San Sebastian, Cadiz, Oviedo, Almeria, and Carthagena.

"**Engineering Magazine.**"—The June issue contains articles on "The Paris Exposition as a Mechanical Achievement," "The Commercial Organisation of the Machine-shop," "The Power Equipment of the Tall Office Building," and "Russian Opening for Anglo-Saxon Enterprise in Asia."

Fareham (Hants).—The Lighting committee has been authorised to enter into an agreement with the Southern Electric Free Wiring Co. for wiring premises in the district on the easy wiring system.

Flash and Search Light Regulations.—The London County Council has just issued bye-laws for the regulation of flash and search lights as follows:—

Flash and Search Lights.

No person shall exhibit any flash light or search light so as to be visible from any street or other other place (whether a thoroughfare or not) and to cause danger to the traffic therein, nor shall any owner or occupier of premises permit or suffer any flash light to be so exhibited on such premises. Any offender shall be liable for every such offence to a fine not exceeding £5.

The expression "flash light" means and includes any light used for the purpose of illuminating, lighting, or exhibiting any word, letter, model, sign, device or representation in the nature of an advertisement, announcement or direction which alters suddenly either in intensity, colour or direction. The expression "search light" means and includes any light exceeding 500 c.p., whether in one lamp or lantern or in a series of lamps or lanterns used together and projected as one concentrated light, and which alters either in intensity, colour or direction.

Fulham (London).—A proposal to expend £23,212 in providing additional electric lighting plant and extending the mains has been adjourned for two months. Up to date 1,176 applications have been received for electric current.

Glasgow.—The Corporation electricity rental to date amounts to £49,884, an increase of £11,986 compared with 1899. The Glasgow and South Western Railway Co. having applied for terms for supplying 660,000 units of electric current annually for lighting St. Enoch station, a sub-committee recommends the supply be given at the same rate as to ordinary subscribers (1½d. per unit), the price to rise or fall as found necessary. In reply to the application by the Police Commissioners of Partick for a temporary supply of electric current to consumers within the burgh until the new works which the Commissioners propose to erect have been completed, it is recommended that supply be granted for 12 months from Oct. 1, at 3½d. per unit, but at no time is the supply to exceed 250 amperes at 500 volts on the three-wire system, the Corporation reserving the right to terminate supply at a month's notice. The latter condition is unacceptable to the Partick Commissioners.

The Corporation are recommended to increase the salary of Mr. W. W. Lackie, chief assistant engineer of the electricity department, from £300 to £375 for the first year and £425 for the second year; that of Mr. J. A. Ward from £225 to £300 for the first year and £350 for the second. The salary of the chief engineer of the tramways department (Mr. W. Clark) is recommended to be increased from £450 to £500 per annum.

Hamilton, N.B.—Messrs. M. Buchan and Hogarth have been instructed to prepare a preliminary report as to the probable cost of an electric lighting scheme. The Council have withdrawn their opposition to the Hamilton, Motherwell and Wishaw Electric Tramway Bill, which, with the exception of the Larkhall section, had already passed the Commons. By arrangement with the promoters, the Council were to receive £10,000 for street improvements. They, however, considered this inadequate, and the promoters' offer of a further £1,500 has been accepted.

Hammersmith (London).—The question of the reduction of the charge for electric current to a uniform 3d. per unit has been referred to the Electricity committee.

Inverness.—Mr. E. G. Craven, who has reported to the Council upon the tenders sent in for the supply and erection of electric

Digitized by Google

generating plant, &c., seems to have fallen foul of many of the tenderers. Messrs. Crompton and Co. complain of the manner in which Mr. Craven has treated their tender in making up his report to the Council. Their figures, it appears, have been reduced from £21,446 to £21,338, and from this must be deducted a credit of £497 for multipolar dynamos, making this firm's total figure £20,841 against the Brush Company's tender of £21,060 Mr. J. Stuart, manager of the Haythorne Tubular Boiler Syndicate, complains of the statement that his firm intended to experiment with their boiler at Inverness, and states that the Haythorne boilers offered were those having all the latest improvements, all of which, except in two small details, have been tested and approved by experts. Messrs. Lowdon Bros. and Co. state that they have quoted for a 1,500 ampere hour E.P.S. battery at nearly £4,000, but now find that an 800 ampere-hour battery was the one on which their prices were based. This would, they urge, reduce their contract price of £21,862 by nearly £2,000, making it lower than any other tender. Other complaints are made with regard to Mr. Craven's handling of the tenders. Mr. Craven, in his turn, appears to have a grievance, his complaint being that he was compelled to expend a larger sum for travelling and hotel expenses than was allowed for by the Council. The correspondence in connection with this matter is to be printed and distributed amongst members.

Japan's Imports.—There was imported into Yokohama in 1899 electric light apparatus to the value of £24,899, electric wires and cables £12,035, submarine telegraph cables £16,394, and telephones, telephone parts, and accessories £26,058. The latter item shows an increase over 1898 of about £11,000.

Jedburgh.—The Police Commissioners have accepted Messrs. Crompton and Co.'s proposals for establishing electricity works in this town. A provisional order is to be applied for.

Kendal.—The consulting engineers (Messrs. Handcock and Dykes) have been instructed to prepare plans and specifications of an electric lighting scheme.

Kilmarnock.—The Council have decided to apply for powers to borrow £50,000 for establishing electricity works.

Kirkcaldy.—Prof. Kennedy has been instructed to prepare plans and specifications of a joint electric lighting and tramway scheme.

Leamington.—Mr. Robert Hammond has been retained as consulting electrical engineer by the Council. A deputation has been appointed to confer with the local tramway company on the proposed acquisition of the tramways by the Council.

Leeds.—On the recommendation of the Lighting committee it has been decided to apply for further borrowing powers for £27,573 for electricity supply. It has also been decided to form a reserve fund, to be called the "Electric Lighting Equalisation Fund," and £8,287 from profits on the electric lighting undertaking has been transferred to this fund. The Council on Wednesday authorised the committee to let contracts for two additional sets of generating plant and for condensing plant at a cost not exceeding £15,000.

Leyton.—In the last report presented by the Electric Lighting committee it was stated that 60 arc lamps are now employed for public lighting. Extensions of the mains have been authorised.

Light Railways.—The following is a list of the applications lodged during May with the Light Railway Commissioners for powers to construct light railways :—

Barnsley & District (Extensions, No. 2)	Mid-Anglian (Amending).
Bath and District.	Nidd Valley.
Blackburn, Whalley and Burnley.	Norwich and Dereham.
Cleobury, Mortimer & Ditton Priors.	Pwllheli and Nevin.
Deanhead.	Rhyl and Prestatyn.
Durham and District.	Sheerness and District.
Hayling Island.	Southwold (Extension).
Hyde and Dukinfield.	Staines and Egham.
Jarrow and South Shields.	Swansea and District.
Kidderminster and Bewdley.	Wales and Laughton.
Kingston, Surbiton & District (Extns.)	Warrington & Northwich (Extension).
Mansfield and District (Extensions).	Warrington and Runcorn.

An inquiry was held last week into the application of Mr. J. Fell and others to construct light (electric) railways in Wakefield and the adjoining districts of Horbury, Outwood, Sandalagna and Alverthorpe. The local authorities interested supported the scheme, and Mr. Robert Green (Pritchard and Co., consulting engineers) gave technical details. The estimated cost of the lines, which will be constructed to the standard gauge, was put at about £82,000, and the overhead electric system will be adopted. The Commissioners announced that they were prepared to recommend the granting of the order.

The Cheltenham-Cleeve Light Railway order has been approved by the Board of Trade.

Manchester.—The foundation stone of the extensive car shed to be erected at Queen's-road, Cheetham, was laid on Tuesday by the chairman of the Tramways committee (Mr. D. Boyle), who said that the works were the first step towards the realisation of the Corporation electric tramway system. The shed would provide accommodation for 252 cars. The area to be covered was about 4 acres. The shed, when completed, would have a front 85 yards long by 11 yards wide. There would be an entrance gateway 16ft. wide to a covered approach road 48ft. wide, with track lines leading to 14 bays of sheds arranged at right angles thereto. These sheds would be 37ft. wide, and would each contain 18 cars. A pit would be formed in 11 of the sheds for examination of the motors beneath 198 cars, while the remaining three sheds would be for 54 trailing cars, to stand on the solid ground. The principals of the shed roofs would contain over 400 tons of steel, carried by steel girders on about 100 cast-iron columns, and the roofs would be covered by boards and slating and about 60,000 square yards of patent glazing. Three gateways 14ft. wide would be provided as emergency exits only, to provide for any temporary block in the entrance roadway. The tracks and connections within the shed were equivalent to a length of 2 miles of single line of tramway, and consisted of 14 bays, three tracks in each bay, branching off from a double line running parallel with the wall of the shed abutting on the intended street. Each track would take six cars, thus accommodating a total of 252 cars. A pit with an area of 6,500 square yards, 4ft. 6in. deep, would be provided under 11 of the bays for the inspection of the car trucks and motors. The tracks would be supported on steel stanchions, with girders formed of the old rails from the existing lines in the city, which are to be reconstructed. Free access would be obtained over the whole area of the pit, to allow of 200 cars being under inspection at one time. The total weight of the steelwork in the tracks and connections would be about 500 tons, and in the stanchions and girders for supporting the tracks about 250 tons. The total estimated cost of this work was £11,000. The shed and pit would be lighted by electricity. It would be, when completed, the largest car shed in Europe certainly, and perhaps the largest of the kind in the world. It would be necessary to have three additional sheds of almost equal size, and probably one or two smaller ones, for other roads. The substitution of electric for horse traction made a great difference in stabling, and the cost would be small.

Mr. W. H. Vaudrey, who was recently elected chairman of the Telephone committee, in succession to Mr. Southern resigned, declines to accept the honour.

Municipal Insurance.—A conference of delegates appointed by Metropolitan local authorities was held last week at the Shoreditch Town Hall for considering the question of Municipal Mutual Insurance. Mr. Joseph Cox, J.P., chairman of the Shoreditch Vestry, presided. A statement, prepared by Dr. H. Mansfield Robinson, clerk to the Shoreditch Vestry, showing approximately the value of the fire and other insurances effected by 55 out of 76 of the central and local authorities in London, was circulated, and showed that the total amount of insurances, including those for fire, employers' liability and fidelity was £8,979,468 ; the annual premiums amounting to £13,967 ; the annual losses by fire during the last five years amounted to only £8,650. 15s. 1d. ; the claims paid by the insuring companies under the Employers' Liability Act were £613. 10s. 1d., and there were no losses under the fidelity policies. A resolution urging the desirability of establishing a municipal insurance fund was carried in a form pledging the conference to the adoption of a system of mutual insurance against fire and other risks. A further resolution authorising the appointment of a representative committee from the delegates present for drawing up a scheme is to be submitted to a future conference.

Oldham.—The question of placing the contract for boilers for the new electricity works was considered by the Council on Wednesday. Owing to the necessity to economise space water-tube boilers will be adopted instead of Lancashire boilers, as originally proposed.

Para.—There is stated to be an exceptional demand just now for electrical goods and appliances for Para and district, which is one of the best parts of Brazil from a business standpoint. Para is to have an elevated railway if Dr. F. Bolonha, an enterprising citizen, is able to secure a franchise from the municipality to form a company to build the road, which is very much needed. It is considered probable that the franchise will be granted. There is at present a poorly-equipped horse-car line, which is in the market. The present company owns a concession which has 50 years to run.

Presentations.—Mr. E. J. Taylor, who was recently appointed chief assistant at the Birkenhead tramway power station, was last week presented with a dressing case by the employés at the Kelham Island (Sheffield) power station.

On Wednesday Mr. A. H. Gibbings, who recently resigned the position of city electrical engineer at Bradford in order to engage in consulting work, was presented with a testimonial subscribed to by about 100 members of the staff of the Bradford electricity department. The presentation consisted of a keyless gold hunter watch for Mr. Gibbings, and an electro-plated fruit stand and a set of flower vases for Mrs. Gibbings, and took place at the Valley-road electricity works. Mr. T. H. Shaw, chairman of the Electricity committee, who made the presentation, spoke in high terms of the ability displayed by Mr. Gibbings, and alluded to the good feeling which had marked the relations between Mr. Gibbings and the staff. Mr. R. A. Chattock, recently appointed City electrical engineer, and

Digitized by Google

other members of the staff also spoke, and Mr. Gibbings suitably acknowledged the presentation.

Prevention of Diseases.—The Hammersmith (London) Vestry has received a report from the medical officer of health, Dr. A. C. Collier, L.R.C.P., L.S.A., setting out the means to be adopted to prevent the spread of consumption and other pulmonary complaints. The rules include the following:—

Where practicable the electric light should be used for lighting purposes in dwelling-houses and other occupied buildings, as nothing tends more to the production of consumption than the breathing of an atmosphere charged with the products of combustion, whether such products are the result of overcrowding or otherwise.

Rhondda.—A provisional electric lighting order is to be applied for by the Council. The question of seeking light railway powers has been adjourned for a month.

Rhyl.—Sanction to a loan of £19,000 for electricity supply has been received by the Council.

Royal Patronage of the Motor Car.—The Prince of Wales has patronised the auto-motor vehicle, and makers and others interested in this branch of enterprise anticipate that this will give a much-needed impetus to the industry in this country, where so far not much has been effected. At the Ascot Royal Hunt Meeting this week His Royal Highness in his motor carriage was conspicuous. A Daimler vehicle built in this country, but with a French-made under frame and wheels, has been selected for the Prince of Wales' use.

Salford.—Wholesale resignations from membership of the Electric Light committee are the order of the day. On Wednesday the Council were invited to appoint successors on the committee to Ald. Snape and Messrs. Haworth and Wilkinson. The Mayor announced the receipt of a joint letter of resignation from Messrs. Ward and Williams. Mr. Bates gave verbal notice of his resignation, and the Mayor said he had been authorised to convey to the Council a similar intimation from Mr. M'Mechan. Mr. Jackson, after stating that the committee were divided upon a certain line of policy, proceeded to describe at considerable length the causes of disagreement, and the reason for some of the resignations. A resolution by Mr. Broxap, in favour of referring the matter of reconstituting the committee to the Selection committee, was, after a rather lively discussion, adopted.

Sheffield.—The accounts of the Tramway department for the year ended March 25 were submitted to the Corporation on Wednesday by Ald. Clegg, chairman of the Tramways committee. He reminded members that, with regard to the electrical part of the undertaking, they only started from Sept. 5, 1899, and went up to March 25. The approximate street mileage at present was 13½ miles, compared with 10¾ in the corresponding period of 1899. The number of miles run was: Horse traction, 815,728; electric traction, 527,292—total, 1,343,020 miles, compared with 841,871 for 1899. The number of passengers carried was: Horse 11,494,400, electric 7,715,314, total 19,209,714, against 10,548,445. The average number of cars running had been 36·3 horse, 32 electric. The average number of passengers per car per week had been: Horse 6,072, electric 8,355. The average traffic revenue per car per week had been: Horse £28. 15s. 11d., electric £32s. 12s., against £28s. 2s. 8d. for 1899. The total revenue had been: For horse traction £57,330. 17s. 9d., electric traction £30,436. 17s.; total £87,767. 14s. 9d., against £58,594. 9s. 8d. for 1899. The working expenses had been:—Horse, £40,304. 4s. 10d.; electric, £23,961. 0s. 8d.; total £64,265. 5s. 6d. The number of passengers carried in the week ended Sept. 3, 1899, which was the last week of the entire horse traction, was 264,103, and of the following week, the first of joint horse and electric traction, the number was 417,299; and for the week ended June 10 they carried 733,374, which was a record. The committee recognised that they were not coping with the traffic, and in his judgment they would not be level with the traffic for 18 month or two years. With regard to the electrical portion of the undertaking in producing the energy, the actual cost of generating the electricity for the tramways at the Kelham power station was 0·824d. per unit. That was the average cost since the cars started running. The cost per unit from Sept. 4 to Dec. 25 was 0·871d., and from Dec. 25 to March 25, 0·777d. With all the charges for office expenses, interest, sinking fund, depreciation, rates, taxes and insurance added, the average total cost per unit was 1·513d., or about 1½d. That was an exceedingly satisfactory figure, and he hoped that for the corresponding period next year they would be able to produce energy at even a lower sum than that. The working expenses for the year had been £51,446, against £32,988 last year. The interest on loans had been £10,924. 11s. 7d., against £5,076. 12s. 11d., an increase of £5,847. 18s. 8d. The repayment of loans last year was £2,640. 4s. 11d., and for the year just ended £7,168. 9s., an increase of £4,528. 4s. 1d. The traffic and other receipts for the year ended March 25 was £87,767. 14s. 9d., against £58,594. 8s. 8d. The balance, after payment of all charges, with the exception of reserve and depreciation, had been close upon £18,228. 9s. 8d., against £17,789 2s. 1d. They had also written off on ordinary depreciation account £4,166. 3s. 7d., against £3,518 8s. 1d. They had set apart for reserve and for maintenance and renewals of tracks and lines £5,800 this year, which sum was absent last year, and for the maintenance of the electrical equipment and power station £2,852. 17s. 5d., which also was a new item, making a total increase of expenses and reserve fund of £19,676. 5s. 8d., compared with last year. The net surplus was £5,409. 8s. 8d., compared with £14,370. 4s. The profit made was more satisfactory than he anticipated, and in his judgment they had got over the critical time. He impressed upon the committee the necessity of keeping the net surplus (£20,000) in hand, because he foresaw that they might have to call up a portion of it to meet a deficiency upon the year's working of the electrical trams, as they had such a large amount of capital entirely unproductive. But he was glad to say that after providing for everything they had a profit of £5,000.

The Corporation on Wednesday adopted a scheme for the reorganisation of the staff of the electric tramway department. Mr. A. L. C. Fell, the present electrical engineer, has been made general manager, and his salary increased from £450 to £600 per annum. Mr. H. E. Yerbury, assistant electrical engineer will occupy the same position as at present, but will also superintend the Kelham power station, his salary being increased from £200 to £220 per annum. Mr. Joseph Dugdale will act as traffic superintendent under Mr. Fell's direction, and his salary has been increased from £150 to £200 per anuum. Various other alterations have been made, including the termination of the engagement of the manager of the undertaking, Mr. Henry Mallyon.

Southport.—It is anticipated that the electric tramway routes will be ready for working by the end of the month.

Southport and Cheshire Lines Extension Railway.—The *Engineer* states that a scheme has been formulated by Mr. R. H. Scotter for converting this railway into an electric railway for passenger service only, leaving the line to be worked by steam, as it now is, for long-distance and goods traffic. Current for working several miles of the line is to be taken from the Southport Corporation mains. To bring Southport into touch electrically with Manchester and Liverpool, Mr. Scotter proposes, by arrangement with the Cheshire Lines Committee, to also convert a piece of line running from the terminus of the extension system through Aintree, and turning off in a south easterly direction to Huskisson station, Liverpool, into an electric line; and further to immediately seek powers to construct two tunnels, suitable for electric passenger service only, from Huskisson under Liverpool to Central Station Low Level.

Swiss Telephone Service.—The revenue derived from the telephone service in Switzerland shows a steady increase. At Dec. 31, 1898, there were 31,918 subscribers, an increase of 3,072 over 1897. At Dec. 31, 1899, the number had increased to 35,056. The revenue in 1899 from subscribers was £95,200, compared with £83,312 in 1898, and the revenue from telephone conversations realised £107,800 in 1899, against £82,400 in 1898.

Sydney (N.S.W.).—The City Council have adopted the report of Major Cardew (Messrs. Preece and Cardew) on electric lighting, an abstract of which appeared in our issue of May 18.

Telephone Municipalisation.—After conferring with the Council of the local Chamber of Commerce the Bradford Telephone sub-committee recommend their Corporation to enter into a new agreement with the National Telephone Co. for wayleave facilities, such agreement being subject to determination on six months' notice. There is a desire to know the result of the Glasgow experiment before taking any steps to establish a municipal telephone exchange, and consequently this matter has been shelved for the present.

Telephonic Distribution of News.—According to the *Electrical World* of New York, companies have been formed in the States of Ohio, Indiana, and Illinois, for the collection of news in each State, and its distribution to the various newspapers by telephone. The daily papers in the smaller towns are said to have found the system very useful.

Tiverton.—A report on the proposal to establish electricity works will be considered at the next meeting of the Town Council.

Tunbridge Wells.—Last week the Town Council considered the report of Sir W. H. Preece (Messrs. Preece and Cardew) as to the alleged nuisance by smoke and vibration at the electricity station. The report stated that:

As regarded the smoke nuisance, the chimney erected in 1894 was 90ft. high and about 5ft. diameter. It was sufficient for working plant of 600 H.P. The present output of the station exceeds 450 kw., equivalent to about 700 H.P. It was, therefore, already too small to meet the enormous growth of the electric light undertaking, and this was undoubtedly one great cause of the trouble with the smoke. During last winter it had been exceedingly difficult at times to obtain good steam coal. The engineer (Mr. Horace Boot) had, therefore, been compelled to use coal of an inferior quality, which was bound to increase the smoke. Anything available had to be used, and nothing but Mr. Boot's energy prevented a stoppage. It was also unfortunate that the houses on the opposite hill were approaching the level of the top of the present chimney, and, therefore, when the wind was in a certain direction, any smoke produced was blown towards these houses. The fact that the station had been working practically with-

Digitized by Google

out trouble for some five years showed that the chimney itself had done well, and it was merely a question of the station having outgrown the capacity of the chimney. The nuisance would now cease, for the heavy winter load was over. The remedies for overcoming this difficulty were simple. They were: (1) To erect a larger and higher chimney, (2) to use smoke consumers, and (3) to have plant in the station sufficient to meet the demand. He recommended them to erect a chimney 180ft. high and 8ft. diameter, which would cost about £2,000, and would be sufficient for a plant having a capacity of 2,000 H.P. It would be possible to economise by building an iron chimney, but such a chimney required painting at frequent intervals. He would suggest that estimates be obtained for both kinds.

Regarding noise, this was, in Sir W. H. Preece's opinion, entirely due to the exhaust steam. There was some vibration set up in the buildings from the Ferranti engine, but it was not communicated outside, and was not therefore a source of complaint. The exhaust steam was discharged into the air at a low level, and nothing had been done to modify in any way the constant thud produced by the enormous quantity of steam which was emitted at every revolution. A great deal of this could have been avoided by placing a damping cylinder of large diameter in the exhaust pipe, but as a large condensing plant had now been ordered the whole of the difficulty from the exhaust steam should be removed.

Regarding the plant in general, he was not at all pleased with the working of the Ferranti engine. It had not been taken over nor fully paid for, and he strongly recommended them to have a second 400kw. Willans Ferranti set ordered without delay, which would only be available for the winter of 1901-2. The present Ferranti engine and dynamo should be used as a stand-by or an emergency set. He estimated the cost of the additions to be: Chimney £2,000, new Willans-Ferranti set £4,600, and contingencies £500, making a total of £7,100.

Sir Wm. Preece further reported that he understood from Mr. Boot that considerable difficulty had been experienced with the Babcock and Wilcox boilers through bad water, and that the Council were going to instal two Lancashire boilers. There was equal danger with Lancashire boilers if bad water was allowed to be used. It appeared to him to be absolutely necessary either to change the source of supply or to have a proper water purifying plant (if one existed) installed, which should deal with the water chemically before it was used in the boilers. The present water could be used for cooling purposes. He did not consider that the site was applicable to a larger horse-power than the present additional 2,000. As soon as it was evident that the full capacity of the present station was being reached they should take steps to build a larger station well outside the town. Electric tramways would soon be required, and other demands on their station would be largely increasing. Heating and motive power for lifts in private residences, as well as for small industries and tools, were becoming quite fashionable. No one could predict the future of electrical development. The new station should be erected where there was a convenient water supply for condensing purposes, and where it would be possible to combine the boiler plant with a destructor. A second power house would be not only a great security against accident, especially from fire, but enable them to cover their area with a system of connected and self-supporting mains so as to reduce any cause of stoppage of supply to a minimum.

The Lighting committee, after considering the above report, advised the Council to at once proceed with the erection of an additional chimney and to obtain tenders for the execution of the work, to purchase a second 400 kw. Willans-Ferranti set with the necessary additional boiler, and also to employ Sir Wm. Preece to superintend the carrying out of the works on the usual remuneration of 5 per cent. on the outlay. Councillor Robb moved the adoption of the report, and said the committee had been continually harrassed by complaints during the past year, and in the interests of the undertaking it was to be regretted that one or two slight failures had occurred. They had been working with insufficient plant. Financial success had been obtained by putting undue pressure on insufficient plant, and the question was what they were going to do in the future? An increase in plant had already been decided upon, and part of it would be delivered in time for next winter's load. That would give a total capacity of nearly 2,000 H.P., and Sir Wm. Preece recommended a still further order of plant in view of continued growth, and the use of electrical energy was extending in all directions. The first thing to do was to have not only adequate plant, but spare plant. The present equivalent number of 8 c p. lamps connected was 32,500. The greatest demand on the works at any one time was 40 per cent., or 12,660. Their present plant was equal to supplying 30,000 lamps, and Mr. Boot was of opinion that the proposed addition would meet their requirements for some time to come, as this would give them a capacity of 45,000 to 50,000 lamps. Even taking the percentage in use at a given time, it would not exceed 50 per cent., so that there should be a margin. They would be incurring a great responsibility by disregarding the advice of their expert, but at the same time a large expenditure would be involved, and would bring the capital involved up to £17,000. He felt the site selected for the central station was unfortunate, but they had now to make the best of it. He put it to Sir William Preece whether the Council should remove their works and combine it with a destructor or tramway plant, but Sir William did not recommend that, because he considered the present nuisance was remediable. He feared they must not look for profits in the future as in the past now that they had this large additional expenditure to meet. It had been very nice to hand over profits to the reduction of the rates, but their plant must not be overdriven to make profit for the rates. A municipal undertaking was not to be regarded only for what could be made out of it. Councillor Dodd moved that the report be referred back. He considered the policy of purchasing plant, which would not be required for three years, was questionable. He objected to the employment of Sir William Preece as unnecessary. There was also the tramway question, and he wanted the committee to consider how that scheme would be affected by the present proposals. The Town Clerk said certain points had been raised by Mr. Boot in a letter addressed to the committee, and Sir William should have an opportunity of dealing with these points. It was then agreed that the report be referred back.

An additional main is to be laid from the electricity works to the Mount Pleasant sub-station at a cost of £516, and the main in the lower portion of Upper Grosvenor-road is to be extended at an estimated cost of £406.

Vladivostock.—The municipality of this city has prepared a specification and schedule for the construction and equipment of 20 miles of electric overhead trolley tramroads, and for the establishment of an electricity generating station for the lighting of the town.

Walker.—The Council has received sanction to borrow money for electric light and refuse destructor.

Water Power Utilisation in Italy.—Plant is to be put down by La Società Ferrovie e Tramvie Elettriche Varesine to utilise the water power of the Giona stream for the generation of electric energy. At first three large 500 H.P. alternators driven by turbines are to be put down, electric energy being utilised in the operation of the Luino-Varese electric tramway and for lighting and power purposes generally. Messrs. Brioschi, Finzi and Co., of Milan, have secured the contract for the electrical plant.

Water Power Utilisation in Spain.—It is proposed to put down a plant to utilise the water power of the river Ottaven, in Galicia, for the generation of electric energy and to distribute the same to a number of small towns in the district.

Whitby.—Sanction to borrow £26,000 for electricity supply has been received by the Council.

Wigan.—An agreement has been entered into with Messrs. F. W. Smith and Co. for wiring premises on the hire-purchase system.

Wolverhampton.—The Lighting committee have presented their report for the year ended March 31, together with an abstract of the accounts of the electricity undertaking for the same period. The net result, after payment of interest and sinking fund charge, is a profit of £402. 6s. 11d., against £1,004. 5s. 10d. in the previous year. The sum of £911. 15s. 4d. was also expended during the year out of revenue—viz., £256 for re-wiring armatures and £655. 15s. 4d. for altering fittings, &c., of 121 customers to suit the increased pressure of supply. The profit, together with the amount in hand from previous years (£416. 5s. 4d.), is to be set aside to form a reserve fund. The committee state that the past year has been one of exceptional difficulty. The alteration in the system of supply has necessitated two systems being in operation for the latter six months, involving considerable additional expenditure out of revenue on account of working cost, especially in the consumption of gas and fuel. The considerable increase in the cost of fuel has also had an adverse bearing upon the financial result. The delay in the completion of the battery room at the generating station has seriously handicapped the department, and has affected the efficient working of the undertaking. At the end of the year there were 364 customers, representing the equivalent of 25,184 lamps, connected, against 276 customers and 19,932 lamps in 1899. The units generated were 603,954, against 470,836 in 1899, and the number of units sold was 482,247, against 371,830. The demand for current for power is gradually increasing. At present there are 16 motors, ranging from ½ H.P. to 20 H P., connected. The total maximum supply demanded in 32 watt lamps was 25,184.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

TENDERS INVITED.

Extension of Time.—The date for sending in tenders for the supply, delivery, and erection of overhead equipment for about 16 miles of equivalent single track of tramways, for the Corporation of *Durban*, Natal, South Africa, has been extended. Tenders are to be sent in duplicate to the agents, Messrs. Webster, Steel and Co., 5, East India-avenue, Leadenhall-street, London, E C., by Friday, July 20, or to the town clerk of Durban, by mail delivery, on or about Monday, Aug. 13. See advertisement.

Dudley Corporation invite tenders for condensers, pumps, cooling tower, &c. Specification may be obtained at the offices of the con-

Digitized by Google

sulting engineer (Mr. Reginald P. Wilson), 66, Victoria-street, Westminster, S.W., and tenders must be addressed to the town clerk (Mr. H. C. Brettell), Town Hall, Dudley, before 30th inst. An advertisement contains additional particulars.

Newcastle-upon-Tyne New Tramways committee require tenders for trolley wires and attachments. An advertisement contains additional particulars, and tenders must be delivered at the office of the town clerk (Mr. Hill Motum) by noon of 25th inst. Specification may be obtained from the consulting engineer, Mr. Charles Hopkinson (Messrs. Hopkinsons and Talbot), 26, Victoria-street, London, S.W.

Manchester Tramways committee invite tenders for the overhead equipment of three tramway routes. Specifications may be obtained from the general manager (Mr. J. McElroy), and tenders (addressed to chairman) must be in by 30th inst. An advertisement contains further particulars.

Shoreditch (London) Vestry require tenders for the supply of eight dry-back marine-type boilers, or eight water-tube boilers, with automatic stokers, &c., for their new generating station at Whiston-street. Tenders to Dr. H. Mansfield Robinson, Town Hall, Old-street, E.C., before noon of 19th inst.

London County Council require tenders for the supply (within three months of order) of about 70 arc lamp standards for lighting the Victoria Embankment. Tenders to clerk (Mr. C. J. Stewart), by 10 a.m. July 10.

The Vestry of St. Mary Magdalene *Bermondsey* (London), require tenders for the supply and laying of insulated electric mains, conduits, junction boxes, &c. Tenders before noon of June 18.

Glasgow Corporation require tenders for outside coal storage and steel structure for coal handling, and locomotive travelling cranes for outside coal handling, for their Pinkston power station. Tenders by 5 p.m. 21st inst.

The Guardians of *St. Saviour's* Union require tenders for the erection of electric fire alarms, telephones, &c., and laying fire mains at their infirmary, East Dulwich-grove. Tenders to clerk, John-street West, Blackfriars-road, London, S.E, by 5 p.m. on 21st inst.

Bury Corporation invite tenders for wiring the Art Gallery and Free Library. Tenders to town clerk, Corporation Offices, Bury, by 18th inst.

Tenders are invited for wiring the *Newcastle* Modern School, 6 and 7, Park-terrace, Newcastle-on-Tyne. Tenders to Mr. J. R. Sisling, 7, Park-terrace, by June 23.

Blackpool Corporation invite tenders for the electrical equipment of 15 single truck tramcars. Tenders by 18th inst.

Sutton Coldfield Corporation invite tenders for electricity generating plant. Tenders before noon of June 21.

Bradford Cleansing committee require tenders for five refuse destructors. Tenders by Sept. 8.

Heckmondwike District Council require tenders for the erection of electricity supply buildings. Tenders by 28th inst.

Limerick Corporation require tenders for electricity generating plant. Tenders to town clerk by July 4.

Trimdon (Co. Durham) Parish Council invite tenders for public lighting by electricity or acetylene gas. Tenders by July 17.

Morley Sewage Purification committee require tenders for wiring the new sewage disposal works. Tenders by 19th inst.

Torquay borough surveyor has been instructed to obtain particulars and prices of the most suitable type of motor car for dust collection.

Servian Post and Telegraph authorities invite tenders, till 21st inst., for 27,000 porcelain insulators, 35 tons of iron wire 4mm. dia. and 30 tons of silicium-bronze wire 3mm. dia. Tenders to Post and Telegraph Section of the Ministry of Works, Belgrade.

Spanish Post and Telegraph Authorities, Madrid, invite tenders until 22nd inst. for 10,000 zinc cylinders for electric batteries. Tenders to Direccion General de Correos y Telegrafos.

Galzada de Calatrava (Ciudad Real, Spain) municipality invite tenders for electric lighting concession for 20 years. Tenders to el secretario del Ayuntamiento by July 10.

TENDERS RECEIVED AND ACCEPTED.

Fulham (London) Vestry have received the following tenders for wiring the electric light works :—

Pyke, Harris and Co.	£1,181	0	0	Newsome, Pinching and Walton	795	0	0
Hailey and Co.	1,100	10	0	P. S. Taeker	781	10	0
F. G. Edey and Co.	1,025	10	0	F. Troy and Co.	762	0	0
Ditto	975	10	0	H. R. Gifkins and Co.	753	0	0
Alwyn and Craven	1,000	0	0	Concentric and General Contract Co.	740	0	0
G. Stegmann	980	0	0	T. L. Hellyar	618	7	6
Foote and Milne	874	0	0	Birmingham Installation Co.	487	0	0
National Electric Wiring Co.	840	0	0				
Ditto	812	0	0				

The tender of Mr. S. F. Davidson has been accepted by the Newcastle-on-Tyne Corporation for the erection of car sheds at Byker for £33,750, the whole of the work to be completed by Sept. 1, 1901, and the car body shed to be finished by December next. The following contracts were also sealed on Wednesday: British Thomson-Houston Co. (switchboards), £2,037; British Insulated Wire Co. (underground feeders), about £7,700; and Mr. Nuttall (construction of the tramway along Mosley-street, St. Nicholas'-square, Collingwood-street, and Neville-street to the power station), at schedule prices.

The following contracts were let by the Wigan Corporation at their meeting last week:—Dick, Kerr and Co. (Ltd.), tramcars; W. T. Glover and Co., cables and pilot wire; Askham Bros. and Wilson, points, crossings, &c.; J. Ross and Manx Granite and Silicia Quarries Co., granite setts; Thompson and Co., iron and steel; S. Marsden and Son, bolts; Taylor and Sayers, castings; and J. Elwell, corrugated iron.

Chester Corporation have accepted the tender of Messrs. Babcock and Wilcox for the supply of steam exhaust, feed suction and delivery, and condensing water pipes and valves. The other tenderers were Messrs. Aiton and Co., Alley and McLellan, G. H. Williamson and Co., Tingle and Co., and John Spencer (Ltd.).

Edmonton (London) Guardians have accepted the tender of Messrs. Preece and Co. for the supply of additional electric lighting plant at £1,600. The tender is subject to approval of Local Government Board.

Birkenhead Corporation have accepted the tender of Messrs. Babcock and Wilcox for the supply of steam exhaust, feed water and drain-pipe work, &c., for the tramway power station.

Leyton District Council have accepted the tender of the Western Electric Co. and the British Insulated Wire Co. for the supply of additional feeder cables.

Wimbledon District Council have accepted the tender of the Berrenberg Electric Lamp Syndicate (Ltd.) for the supply of 5,000 16 c.p. incandescent electric lamps at 1s. 5d. each, and that of Messrs. Foote and Milne for wiring the new isolation hospital at £321.

Stockton-on-Tees Council have accepted the designs submitted by Messrs. W. Macfarlane and Co. for arc lamp pillars at £9. 10s. each.

The Barnsley Town Council has accepted the tender of Messrs. Crompton and Co. for supplying and erecting 15 arc lamp posts and arc lamps and attaching incandescent lamps to the posts at £501. 14s.

The tender of Messrs. Crompton and Co. has been accepted for the supply of the whole of the generating plant for the Heywood electricity works.

Cheltenham Town Council have placed a contract with Messrs. Körting Bros. for the supply and erection of condensing plant for their electricity works at £2,100.

Perth Town Council have accepted the tender of Messrs. W. Lucy and Co. for the supply of 45 enclosed arc lamps and ornamental cast-iron and steel pillars, switch gear, &c., at £2,143.

Messrs. Crowther and Co., Manchester, have obtained the contract for the electric lighting of the new Bury (Lancs.) post office.

Battersea (London) Vestry have accepted the tender of Messrs. Norman, Beard & Co., for the erection of a Hope-Jones electric organ at the Town Hall for £1,912.

The tender of Mr. B. Thomas has been accepted by the Llandilo Council for the erection of electricity works at £2,415.

APPOINTMENTS VACANT AND FILLED.

The post of senior demonstrator in the department of electrical engineering and applied physics at the City and Guilds Technical College, Finsbury, will be vacant at the close of the present session. The salary is £150, rising to £200. Applications for the post have to be addressed, in the first instance, to the principal of the college, Leonard-street, Finsbury, London, E.C., by June 29. An advertisement gives some further particulars.

There is a vacancy for an assistant superintendent in the Telegraph Department of the Government of India. Applications to Secretary, Public Works Department, India Office, Whitehall, London, S.W., by June 30. An advertisement contains further particulars.

Birmingham Corporation require two lecturers for the electrical and engineering departments of the municipal technical school in September next. An advertisement contains further particulars, and applications must be sent to the secretary (Mr. Geo. Mellor), Suffolk-street, by 30th inst.

The Council of the King's College, London, invite applications for the post of demonstrator in electrical engineering. Conditions of the appointment can be obtained of the Secretary, and applications must be in by 30th inst. See advertisement.

Digitized by Google

The Board of Works for the Poplar (London) District are open to receive applications for the position of chief generating assistant at the electricity works now in course of establishment for the district, who will be under the direction of the engineer and manager of the electricity department. Commencing salary, £156 per annum. Applications must be sent to Mr. Leonard Potts, clerk, offices of the Board, 117, High-street, Poplar, E., by 18th June. See advtisement.

A shift engineer is required for the Leyton electricity department. Further particulars are given in an advertisement, and applications must be sent to the engineer and manager (Mr. F. Harman Lewis) by 22nd inst.

Carlisle Corporation require a clerk and switchboard attendant for their electric lighting department. Further particulars are set out in advertisements, and applications must reach the city electrical engineer (Mr. Charles D. Burnet), James-street, Carlisle, by Monday the 25th inst.

The South London Electric Supply Corporation require a pupil with previous technical training. Applications to secretary, 54, Bengeworth-road, Loughborough Junction, S.E. See advertisement.

Whitechapel District Board of Works require an arc lamp attendant and a plumbing jointer. Applications to the engineer, 27, Osborn-street, London, E. See advertisement.

The Municipal Electrical Association Council require a secretary to act under direction of hon. secretary. Applications to president (Mr. A. B. Mountain, borough electrical engineer, Huddersfield), by 14th inst.

An assistant master (for physics and mathematics) is required for the Day School of Science, Gravesend. Applications by 21st inst.

The Brush Electrical Engineering Co. have appointed Mr. Edward A. Leeson to be works manager at their Falcon Works, Loughborough, in succession to Mr. C. E. Hodgkin. After many years experience in the design, construction, and working of steam machinery with Messrs. R. and W. Hawthorn, Newcastle-on-Tyne, Mr. Leeson became successively works manager of Messrs. Hawthorn, Guppy and Co.'s works at Naples, and of the branch works of Sir William Armstrong, Mitchell and Co., at Pozzuoli, Italy. He recently returned to this country to take up the position of works engineer with Messrs. Hawthorn, Leslie and Co, Newcastle-on-Tyne. Mr. Leeson's wide experience of steam engine construction, and of the high-class workmanship associated with the names of the firms given above, will doubtless prove of great value to the Brush Company in connection with the increasingly large plants under design and construction for lighting, traction and power purposes at the Falcon Works.

Mr. W. J. Poole, who has been for two years superintending the erection of the plant at Port Dundas station, Glasgow, has been appointed to succeed Mr. John Christie as station superintendent at a salary of £200 per annum.

Mr. H. Bell, the present second assistant at Hull, has been appointed chief assistant at the Sculcoates-lane electricity works, in succession to Mr. H. Gray, who has received an appointment at Accrington.

Greenock Corporation have appointed Mr. W. M. Nelson, late assistant engineer at the Corporation electricity works, to be resident electrical engineer for the burgh in succession to Mr. S. E. Fedden, who was recently appointed to Sheffield.

Mr. Robert Leach, B.Sc., has been appointed teacher of physics and chemistry at the Gloucester Municipal School at a salary of £250 per annum.

BUSINESS NOTICES.

As previously announced, Messrs. Robert W. Blackwell and Co. (Ltd.) have removed their offices and stores from 39, Victoria-street, Westminster, and 133, Bermondsey-street, London, S.E., to central premises at 59, City-road, London, E.C. Telephone Nos. 1479 and 1480 London Wall. Telegrams: "Kurkee London."

On and after June 18 the registered offices of the Metropolitan Electric Supply Co. (Ltd.) will be removed from 29, Baker-street to 16, Stratford-place, London, W.

Messrs. Veritys (Ltd.) are removing their Glasgow offices to 40, Bath-street from June 18.

The offices of Mr. G. R. Peers, consulting electrical engineer, 96, Deansgate, Manchester, are now connected to the National Telephone Co's. system number 08507.

BANKRUPTCIES, LIQUIDATIONS, &c.

A meeting of the principal creditors of Laing, Wharton and Down (Ltd.) (in liquidation) was held under the presidency of Mr. L. B. Warmington, liquidator, at 80, Coleman-street, London, E.C., yesterday. Creditors representing £7,800 were present. Mr. Warmington said a receiver was appointed on Oct. 4, 1899, and the company entered into voluntary liquidation on Oct. 10. The receiver was still in possession, and was carrying on the business as manager under the supervision of the Court pending the completion of certain contracts. From several of these contracts it was anticipated a small profit would be derived, but in the case of other contracts a loss would probably ensue. The contracts would be completed by the end of July, and though the Court had not definitely settled the time for the closing of the liquidation it was unlikely it would sanction any further delay. At May 13, 1900, the state of affairs was as follows:—

Assets.			
Book debts	£7,150	0	0
Contracts in hand (at cost)	3,365	0	0
Cash	1,255	0	0
Stock (estimated)	7,383	9	1
Office furniture, &c. (estimated)	1,490	0	0
Patents (estimated)	48	0	0
Total assets (estimated)	£20,691	9	1
Receivers' Liabilities.			
Running expenses (say)	£1,000	0	0
Debentures and accrued interest	10,801	0	0
	11,801	0	0
Net assets (estimated)	8,890	9	1
Total	£20,691	9	1

Sundry creditors stand for £1,250. Mr. Warmington stated that a cheque had recently been received from the London County Council with £2,700 deducted for defective work, and in connection with this contract an action was pending against the firm who supplied the cables. There was also another action pending against Clench and Co. Mr. Warmington further stated that there was a good general business still going on, and over £6,000 worth of work had been done in six months. There were no secured creditors beyond the debenture holders. About £30 per week was being spent in office and other salaries, and the question that remained was, what was to be done with the business, seeing that the Court would not allow them to continue much longer. A lengthy discussion ensued, especially on the point of the value of the stock, and it was ultimately agreed that a committee of inspection should be appointed, consisting of Mr. Geo. Sutton (Henley's Telegraph Works Co.), Mr. H. Oppenheimer (International Electric Co.), Mr. Teale (Keeling, Teale and Co.), and Mr. Barnard (Pfeil and Co.), who are to make an independent valuation of the stock and report.

The official receiver and liquidator of the Cox Thermo-Electric Co. (Ltd.) (Mr. H. Brougham) notifies that he is about to apply to the Board of Trade for his release. In the summary of receipts and payments now issued it is shown that the assets of the company (£257. 9s.) were covered by the debenture bonds, and also that the debenture-holders, whose claims amounted to £10,000, received nothing in respect of their security. It will be remembered that the directors of this company voluntarily offered to pay the trade creditors 13s. 4d. in the £ on the amount of their claims, and, while this offer was renewed to the official receiver, the directors, after protracted negotiations, declined to carry it out, which seems to require some explanation on the part of the directors, many of whom are well known in the electrical industry. In connection with the formation and promotion of the company, the official receiver states that there was nothing to justify an application for a public inquiry. The directors of the company were Mr. Roger Wallace, Q.C., Mr. Julius Möeller, Mr. J. Brown Martin, and Mr. H. B. Cox.

A. W. Hirst, electrical engineer (trading as Hirst and Co.), St. Michael's-road, Croydon, has been adjudicated bankrupt. The first meeting of creditors will take place on 21st inst., at 24, Railway-approach, London Bridge, and the public examination on July 16, at the County Court, Park-street, Croydon.

At the London Bankruptcy Court on Wednesday John Henry Crawford, financial agent, late of Cannon-street House, London, E.C., applied to pass upon accounts showing total liabilities £25,615, and assets valued to show a surplus. Debtor had previously failed in 1894 in the name of Grant Crawford, and recommenced business in 1895 with £600 borrowed capital. In 1897 he formed the London Provincial Electrical Co. (Ltd.), with a capital of £60,000. Early in 1896 he had purchased for £3,000 in cash and shares the business of a Birmingham firm of electrical engineers and patents relating to an arc lamp, the London Provincial Electrical Co. taking over the business and patents for £30,000. A winding-up order was made against the company in 1898, and it remained in liquidation until January last, when the creditors other than debtor received payment of their debts, and the company was released. Debtor stated that he had expended between £6,000 and £7,000 upon the company, which still has offices at Palmerston-buildings, E.C. Examination concluded.

A meeting has been called to consider the recommendation of the directors to wind up voluntarily, for re-construction purposes, Earle's Shipbuilding and Engineering Co. (Ltd.).

Digitized by Google

For Sale.—In our advertisement columns Messrs. Wheatley Kirk, Price and Co. announce the sale by auction, at the Grays Engineering Works, Grays, Essex, on Tuesday, Wednesday and Thursday, July 3, 4, and 5, at 10 for 11a.m. prompt, the contents of the works, including a variety of tools, machinery, utensils, stores, &c. The whole may be viewed on Monday, July 2 and on the mornings of sale. Catalogues (6d. each) may be obtained on application at the works, of Messrs. Hatten and Asplin, solicitors, Bank Buildings, Grays, Essex, or of the auctioneers, 49, Queen Victoria-street, London, E.C., and Albert-square, Manchester.

Business for Sale.—Large and well-equipped electrical engineering works, including 20 years' lease, are for sale. Applications should be addressed "Bargain," care of J. W. Vickers, 5, Nicholas-lane, London, E.C. See also advertisement.

Westinghouse Plant.—A booklet on the Westinghouse electro-pneumatic system for controlling railway and other motors has just been issued by the British Westinghouse Co. Illustrations which accompany the text include a two-car shuttle train equipped with this system, and the drawing of a two-car shuttle train showing motors and controllers with electro-pneumatic operating devices in position. The Westinghouse system is applicable to the simultaneous operation of any number of motor cars in a train, and it is claimed that the advantages of this system become more apparent as the number of motor cars in a train is increased.

General Electric Plant.—A new list of desk and ceiling fans for use on continuous and on alternating current circuits is issued by the General Electric Co., and also a new list of Crocker-Wheeler multipolar motors and generators for belt driving and direct coupling from 10 H.P. to 750 H.P. These sectional lists will be incorporated in the new edition of the company's full catalogue now preparing. The company will supply copies of the new lists on request.

Imports of Electrical Goods into the United Kingdom.—The accounts relating to the trade and navigation of the United Kingdom show that the value of electrical goods and apparatus imported during May was £78,350. The total for the five months ended May 31 was £334,082.

Fire.—A fire broke out on Thursday last on the premises of Mr. F. C. Allsop, 126, Queen Victoria-street, London, E.C. The contents of a large showroom on the first floor were destroyed. The damage is estimated at about £1,000.

"Burnand" Transformers.—A new price list of Burnand transformers is just published by Messrs. W. E. Burnand & Co., Ocean Works, St. Mary's-road, Sheffield. In addition to the usual particulars as to dimensions, efficiencies, &c., the list contains information regarding these machines and sectional drawings and photographs of interest.

Emery Grinding Machines.—Messrs. Poth, Hille & Co., 27, Leadenhall-street, London, E.C., are introducing the "Excelsior" improved stop foot-power emery grinding machine, which the makers claim will do all kinds of grinding in less than one-fourth the time required on an ordinary grinding stone, and can be attached to any work bench. The apparatus is simple and compact, and there are but few wearing parts.

Exports of Electrical Apparatus and Material.—The following list gives official particulars of the exports of British manufactured electrical apparatus and material (including telegraph and telephone wire and material, but not including electrical instruments or machines, which are not separately specified) from June 7 to June 12, with the ports of destination:—

Africa—Alexandria, £16; Beira, £597; Cape Town, £295; Durban, £80; Port Said, £15. *Argentina*—Buenos Ayres, £150. *Australasia*—Adelaide, £234; Auckland, £289; Brisbane, £81; Fremantle, £27; Melbourne, £393; Port Chalmers, £49; Sydney, £487; Wellington, £238. *Belgium*—Brussels, £55. *Brazil*—Rio Janeiro, £1,406 (including £1,369 telegraph material). *British Guiana*—Demerara, £57. *Burma*—Rangoon, £198. *Canada*—Halifax, £70. *Ceylon*—Colombo, £731. *China*—Shanghai, £442. *France*—Boulogne, £16. *Germany*—Hamburg, £400 (telegraph material). *Gibraltar*, £25. *Holland*—Amsterdam, £53. *Hong Kong*, £14. *India*—Bombay, £530; Calcutta, £842. *Java*—Sourabaya, £60. *Malta*, £789. *Russia*—Archangel, £361; St. Petersburg, £153 (including £52 telegraph cable). Total (for six days) £9,153, against £12,355 for one week last year (June 7 to 13).

ELECTRIC AND GENERAL INVESTMENT CO. (LTD.)—Subject to audit, the directors have decided to recommend the payment of the following dividends, &c., for the year ended May 31:—Ordinary shares: A dividend of 5s. per share, of which 2s. per share was paid on account in December last, and a bonus of 4s. per share, making a present distribution of 7s. per share, or a total distribution of 9s. per share for the year. Founders' shares: A dividend of £30 per share and a bonus of £40 per share, making £70 per share for the year. The dividends will be paid on 27th inst.

COMPANIES' MEETINGS AND REPORTS.

British Electric Traction Co. (Ltd.).

The report of the directors of this company, for the fifteen months ended 31st March last, states that the profits, including £35,451. 13s. 8d. brought forward (but without taking into account the premiums, £160,529. 15s. 3d., received in respect of new share and debenture capital), amount to £159,122. 15s., and after deducting the proportion of general expenses chargeable to revenue, and also the expenses incurred in connection with schemes not proceeded with and written off, and interest on debenture stock, there remains a net profit of £130,174. 16s. 2d. The directors propose to reduce goodwill account by £5,000, add to reserve £20,000, reduce furniture account by £469. 1s. 9d., and to pay the dividend at the rate of 6 per cent. per annum on the preference shares (on account of which interim dividends have been paid to Feb. 15, 1900), absorbing £23,051. 18s. 9d., and a dividend at the rate of 8 per cent. per annum on the ordinary shares (on account of which an interim dividend at the rate of 6 per cent. per annum has been paid for the nine months ended Sept. 30, 1899, leaving a balance dividend payable of 11s. per share on Nos. 1—30,000, and 8s. 7½d. per share on Nos. 60,001—75,000), absorbing £37,869. 16s. 10d., carrying forward £43,783. 18s. 10d.

Since Dec. 31, 1898, the directors have issued 40,000 6 per cent. cumulative preference shares of £10 each at £12 per share, and 15,000 ordinary shares of £10 each have been allotted to the shareholders at £15 per share. There has also been issued £250,000 5 per cent. perpetual debenture stock at an average price of £120⅛ per cent. The total premiums received in respect of these issues, after deducting expenses, amount to £160,529. 15s. 3d., and the whole of this amount has been added to reserve. The subscribed share and debenture capital is now £1,300,000. Of the authorised share capital there is at present unissued 15,000 ordinary and 10,000 preference shares of £10 each, which the directors propose at an early date to allot to the shareholders. The whole of the present authorised share capital will then be issued, and the directors recommend that powers be taken to increase the nominal capital of the company by the creation of 80,000 shares of £10 each.

Contracts and Undertakings.—The total amount expended under this head, after deducting costs of undertakings transferred, and after writing off expenses incurred in respect of schemes not proceeded with, but including a proportion of general expenses, is £543,246. 12s. 4d.

Investments.—The total expenditure under this head, after deducting cost of securities sold or written off, is £950,280. 0s. 1d. There are certain contingent liabilities in respect of some of these investments.

Superannuation Fund.—The directors have had under consideration the desire expressed by officers of the company and of the associated companies that a superannuation fund should be established, and a proposal will be made at the forthcoming meeting of shareholders that £25 be subscribed by the company in respect of each official now in the employ of the company who elects to become a subscriber to the fund, and that the company should make certain annual contributions to the fund.

An appendix accompanying the directors' report and accounts gives particulars of the contracts and undertakings in which the British Electric Traction Co is interested, and of the nature and extent of the company's investments in these undertakings.

Chilian Electric Tramway and Light Co. (Ltd.).

The report of directors, covering the period since the incorporation of the company (May, 1898) to Dec. 31, states that on May 9, 1898, the company acquired the whole of the horse tramways in Santiago. The company at the same time obtained from the municipality a concession for 30 years for electric traction over the entire system, and also a concession giving the monopoly of supplying the city of Santiago with electric current for lighting for the same period. The company also purchased the suburban line from Santiago to Nunoa for ultimate conversion to electric traction. The profit and loss account shows a balance credit of £18,051. 16s. 11d., and from this the directors propose to pay the dividend of 6 per cent. per annum on the amount of preference shares called up to Dec. 31, 1899 (absorbing £10,871. 18s. 6d.), leaving £7,179. 18s. 5d., out of which various claims have to be provided for. The balance will be carried forward.

The tramways covered by the concession extend to a total length of about 117 kilometres of single track. Horse and mule traction have, up to the present, been used over the entire system, with the exception of a small distance between Calle Mapocho and Brazil; which being the first section converted to electric traction, was opened to public traffic on April 1, 1900. Reconstruction is proceeding rapidly over the entire system, and as the various sections are successively completed and in working order electricity will at once be installed. The concession allows, however, of ample time for the entire conversion of the whole system. During the twelve months from Jan. 1 to Dec. 31, 1899, the company carried 41,743,687 passengers, earning $1,819,143.16. For 1898 the number was 38,896,180, earnings $1,670,583.97. As the tramways were taken over in a very low state of efficiency, the expenditure for maintenance and working has been exceptionally heavy. It is confidently expected that, when the reconstruction is completed and the electric service is installed, there will not only be an increase of traffic, but also a diminution in working expenses. This is the experience in all cities where animal traction has been superseded by electricity.

As regards the concession for electric lighting, the directors believe that it has a very important and promising future before it. There is no reason for doubting that the success of the electric light in South America will be as assured as it is in Europe. The work of installation is being vigo-

Digitized by Google

rously prosecuted, and a large number of cables have already been laid. The works, both for the conversion of the tramway system to electric traction and for installation of the electric light, have been entrusted entirely to the Allgemeine Elektricitäts Gesellschaft of Berlin, under special agreement concluded with the London board, which is a guarantee that the work in every respect will be carried out in the most efficient manner. Accompanying the report is a report of the Allgemeine Elektricitäts Gesellschaft, which gives an interesting resumé of the work that has been accomplished in connection with the conversion of the tramways and the electric lighting installation.

Mexico Electric Tramways (Ltd.).

The directors, in their report for the year ended 31st December, state that after placing £5,000 to a betterment fund, there is a balance profit of £29,852. A dividend of 12½ per cent. has already been declared by the Mexican Board on the ordinary shares of the Mexican Co., and the balance of £4,852. 3s. 6d. has been carried forward. This dividend covers the three years, 1897, 1898, 1899. The London board recommends a dividend of 6 per cent. on the preference shares and a further dividend of 5 per cent. on the ordinary shares, which will absorb £25,603. 13s. 4d., leaving £1,069. 5s. 4d. to be carried forward. During the year the company issued £130,000 6 per cent. debentures (balance of £400,000), to pay for the first section of reconstruction of the lines. This company is also now the owner of the total share capital of the Ferrocarriles Co. The results of the working of the tramways for the year show a considerable increase of traffic, which will increase as the proposed conversion of the system is completed. Of about 150 miles of single line of tramway track about 17 miles is operated by electricity, 19 miles by steam and 125 miles by animal traction. During the past twelve months the earnings were £190,347. 14s. 7d., against £179,523. 18s. 1d. for the previous twelve months. The expenditure, during the same period, shows a decrease of £1,880. 17s. 6d. Since that portion of the system which has been converted to electricity was opened to traffic, the monthly returns of passengers carried have shown a gratifying increase.

CHADBURN'S (SHIP) TELEGRAPH CO. (LTD.)—A meeting was held at Liverpool on Friday. The Chairman (Mr. W. Chadburn) remarked that considering the increase in the turnover during the year the result was perhaps not quite so good as they might have anticipated, but adverse circumstances had prevailed in the continued abnormally high price of material, against which they could obtain no corresponding increase of price for their goods. They had a great number of orders on hand—in fact, the prospective work was quite as good as could possibly be expected, and the future was very promising.

CITY AND SOUTH LONDON RAILWAY CO.—A special meeting of this company was held on Tuesday to approve the bill now before Parliament to confer further powers on the Baker-street and Waterloo Railway Co. The chairman (Mr. C. G. Mott) said the bill provided for extending the Baker-street and Waterloo line to Paddington station, and, by a subway, to the City and South London Co.'s Elephant and Castle station. It would be very much to the interests of both companies, and also for the public convenience, thus to connect the traffic of north and south London. The bill contained powers for the two companies to make arrangements in the future for the joint supply of power or the working by the City and South London Co. of the Baker-street line. The resolution was carried. The chairman said that the Clapham and Moorgate-street extensions had been opened and both were going on satisfactorily.

SUSSMANN ELECTRIC MINERS' LAMP CO. (LTD.)—The report of the directors to Dec. 31 states that the Sussmann miners' lamp has become an accomplished working success. The first colliery to test the lamps on a large scale was the South Hetton (Co. Durham) Coal Co., who took 600 lamps on hire for upwards of 12 months. The result of the trial was that they purchased the lamps outright, and eventually ordered a further 400, making 1,000 in all. The adjacent collieries of South Moor and Craghead also placed an order to light one of their pits with 300 lamps on hire in Aug., 1898, which gave such satisfaction that they afterwards also purchased the lamps outright, and in March, 1899, ordered a further 400, making 700. A first order has been executed for an important colliery in New South Wales, while a trial order has been also given by a New Zealand colliery. The lamps have also been tested, with excellent results, in one of the large South Wales collieries. With all these satisfactory results there is a difficulty in inducing colliery proprietors to adopt electric lamps in lieu of existing oil lamps, partly from the greater initial cost and partly the inability of electric lamps to indicate the presence of gas. The directors have endeavoured to meet the first point by reducing the selling price. Sample orders have been executed for various Government departments, including the Royal Arsenal, the Royal Gunpowder Factory, H.M. Dockyards at Portsmouth and Devonport, all of which the directors believe have given complete satisfaction. It is evident, however, says the report, that either further capital must be found, or that the company must suspend operations and go into liquidation. The directors having in view the work that has been accomplished and the success that has been achieved in the lamp itself, believe that an issue of debentures is warranted, and propose an issue of £5,000. The sale of the French and Russian patent rights of the company have been for a long time under negotiation, and a sum of £500 has been paid for the right to acquire them. The prospects of the company that acquired the Belgian rights are reported to be satisfactory. The use of the Sussmann lamp is now expressly authorised by the Belgian Government in some of the principal mines of that country.

NEW COMPANIES, STATUTORY RETURNS, &c.

BRIANNE ELECTRIC LAMP CO. (LTD.)—This company was registered on June 6, with a capital of £30,000, in £1 shares, to enter into an agreement with Mr. M. Hill for the acquisition of certain patents relating to electric lamps, and to carry on the business of electric and other lamp manufacturers, makers of electrical fittings, accessories, appliances, and apparatus, &c. The subscribers are W. Townsend, H. M. Delacour (engineer), Ella Dawson, W. W. Ellwood, H. Clegg, C. C. Willson, and S. Napier. The first directors are J. B. Whyte, M. Kilner, and W. Townsend.

GATESHEAD ELECTRIC AND MECHANICAL SUPPLY CO. (LTD.)—This company was registered on June 6, with a capital of £1,000 in £1 shares, to acquire the business carried on by J. A. M. Collier, and to carry on the business of electricians, suppliers of electricity, mechanical and electrical engineers, makers of electrical appliances, &c. The subscribers are W. E. Brown, S. A. Brown, J. A. M. Collier (electrical engineer), T. Romanis, J. B. Mennie, R. C. Twibell, and W. Brown. The first directors are J. B. Mennie, T. Romanis, and J. A. M. Collier (manager).

JOHN MARSTON'S CARRIAGE WORKS (LTD.)—This company was registered on May 25 with a capital of £75,000, in £1 shares, to carry on business as manufacturers of and dealers in electric, steam, oil, gas, and other motor cars and vehicles at Birmingham.

MOTOR WHEELS (LTD.)—This company has been registered with a capital of £100, in £1 shares, to manufacture and deal in electric and other motors, motor carriages, &c.

BROMPTON AND KENSINGTON ELECTRICITY SUPPLY CO. (LTD.)—According to the annual return to March 29 the capital is £199,500 in 27,900 ordinary and 12,000 preference shares of £5 each, of which 19,661 ordinary and 12,000 preference have been taken up. £5 has been called up on each of 18,661 ordinary and 12,000 preference, and £153,305 has been received.

FOLKESTONE ELECTRICITY SUPPLY CO. (LTD.)—The annual return to April 14, gives the capital as £50,000 in 10,000 shares of £5 each, all of which have been taken up and paid for in full.

GUILDFORD ELECTRICITY SUPPLY CO. (LTD.)—The annual return to April 13 gives the capital as £20,000 in 3,900 ordinary shares of £5 each and 500 founders' shares of £1 each, of which 2,488 ordinary and 500 founders' have been taken up. The full amount has been called up on each share and £12,942 has been received, including £2 paid on two forfeited shares.

W. T. HENLEY'S TELEGRAPH WORKS CO. (LTD.)—The annual return to March 14 has been filed. The capital is £300,000 in 30,000 ordinary and 30,000 preference shares of £5 each, all of which have been taken up and paid for in full.

INDO-EUROPEAN TELEGRAPH CO. (LTD.)—The annual return to May 14 gives the capital as £450,000 in 18,000 shares of £25 each, 17,000 of which have been taken up and paid for in full.

NORWICH ELECTRICITY CO. (LTD.)—The annual return to April 4, gives the capital as £100,000 in £10 shares, 7,000 of which have been taken up and paid for in full.

CITY NOTES.

MEMORANDA.—Bank rate 3 per cent. (June 14, 1900). Price of silver 27 1/16d. per oz. (June 14). Consols (2¾ per cent.) 101⅛—101⅝ for money, 101⅝—101¾ for account; 2½ per cent. 99—100 (June 14). Stock Exchange Settling Day: Consols, July 4; Stocks and Shares Continuation Days, June 26 and July 10; Ticket Days, June 27 and July 11; Pay Days, June 28 and July 12; Mining Share Carry-over Days, June 25 and July 9.

AKTIEN-GESELLSCHAFT ELEKTRICITATSWERKE VORM. O. L. KUMMER AND CO.—A dividend of 10 per cent. has been declared for the past year, against 11 per cent. in 1899.

BOURNEMOUTH AND POOLE ELECTRICITY SUPPLY CO. (LTD.)—The transfer books and register holders of debenture stock of this company will be closed from 18th to 30th inst. inclusive.

CHELSEA ELECTRICITY SUPPLY CO. (LTD.)—The transfer books of the preference and ordinary shares and debenture stock of this company are closed from the 13th to the 30th inst. inclusive, for the preparation of interest and dividend warrants.

CITY OF LONDON ELECTRIC LIGHTING CO. (LTD.).—Notice is given that the transfer books and register of holders of the £400,000 5 per cent. redeemable debenture stock of this company will be closed from 18th to 30th inst. inclusive.

CONSOLIDATED TELEPHONE CONSTRUCTION AND MANUFACTURING CO. (LTD.)—Mr. C. H. Reynolds, C.I.E., late Director-General of Telegraphs to the Indian Government, has been elected a director of the Consolidated Telephone Construction and Maintenance Co. (Ltd.), the Anglo-Portuguese Telephone Co. (Ltd.), and the Edison-Gower Bell Telephone Co. of Europe (Ltd.).

COUNTY OF LONDON AND BRUSH PROVINCIAL ELECTRIC LIGHT CO. (LTD.)—The transfer books and register of holders of debenture stock of this company will be closed from 18th to 30th inst. inclusive.

ISLE OF MAN TRAMWAYS AND ELECTRIC POWER CO. (LTD.)—It is reported that the directors, with the exception of Mr. John A. Mylrea, have disposed of their shares and are no longer qualified. A petition is to be presented to the Deemster in Chambers for winding up the company, and asking for the appointment of Mr. W. H. Walker, one of the liquida-

Digitized by Google

tors of Dumbell's bank, as liquidator. The meeting of shareholders stand adjourned till to-day (Friday).

MUNICIPAL ISSUES.—Bristol Corporation are making an issue of £500,000 £3 per cent. stock, a portion of which is to be utilised for electric lighting extensions.

London County Council has this week issued a 3 per cent. loan at £97 10s. for £5,000,000.

NATIONAL TELEPHONE CO. (LTD.)—The tranafer books of the 3½ per cent. and 4 per cent debenture stocks of this company will be closed from 18th to 30th inst. inclusive.

ST. JAMES' AND PALL MALL ELECTRIC LIGHT CO. (LTD.)—Subscriptions are invited up to this day (Friday) to an issue of £150,000 3½ per cent. debenture stock in this company, offered at £96 per cent., redeemable at par on or after Jan. 9, 1931, at six months' notice, or at 102½ per cent. in the event of the voluntary liquidation of the company, or after Jan., 1911, at six months' notice. The company has a capital reserve fund of £74,493 employed in the business. The net profit earnings for the past five years has increased from £14,580 in 1895 to £31,834 in 1899. The sum required to pay interest on the £150,000 debenture stock now issued, when fully paid up, is £5,250 per annum. The whole of the share capital of the company (£300,000) has been issued and is fully paid, and the debenture stock now open to subscription is secured by a trust deed, which conditions that the company shall not create any mortgage or charge upon any of its freehold property in such a way that it shall rank *pari passu* or in priority to this debenture stock, for which the directors have power to issue from time to time a total amount equal to one-half the subscribed share capital of the company for the time being.

STOCK EXCHANGE NOTICES.—Wednesday, 27th inst., has been appointed a special settling day in 180,000 £1 fully-paid vendors' ordinary shares (Nos. 1 to 180,000) and 25,000 £1 fully-paid vendors' 7 per cent. non-cumulative preference shares (Nos. 115,001 to 140,000) of *Nernst Electric Light (Ltd.)*, and the further issue of 12,500 £5 fully-paid 6 per cent. cumulative preference shares (Nos. 27,501 to 40,000) of the *British Insulated Wire Co. (Ltd)* has been ordered to be quoted in the Official List.

SUNDERLAND TRAMWAY CO. (LTD.)—At an extraordinary meeting of this company on Tuesday it was resolved, consequent upon the purchase of the undertaking by the Corporation, to wind up voluntarily, and to appoint Sir E. T. Gourley, M.P., and Mr. G. Haswell (directors), and Mr. J. W. Alison (secretary) as liquidators. The lines are now being equipped electrically by the Corporation on the overhead trolley system.

WESTERN UNION TELEGRAPH CO.—The usual quarterly dividend of 1¼ per cent. is recommended. The statement of earnings, partly estimated, for the quarter ended June 30 shows net receipts $1,700,000, increase $47,000; balance after charges $1,475,000, increase $47,000; surplus after dividend $258,000, increase $47,000. The total book surplus is $8,556,000, increase $489,000.

NOTES.

As announced in our report on another page, the fifth annual convention of the Municipal Electrical Association opened last Wednesday at Huddersfield, under the able presidency of Mr. A. B. MOUNTAIN. Owing to the comparative smallness of the town selected, and the large body of members and guests who assembled, considerable difficulty was experienced in finding adequate accommodation, many having to seek quarters in the neighbouring larger town of Leeds, where the meetings of to-day and to-morrow are to be held. With a full programme this year, and a more evident intention on the part of the members to make the occasion less of a picnic than in former years, it is probable that the Huddersfield convention will yield results of solid and lasting value.

MR. MOUNTAIN, in his presidential address, contented himself with the useful service of placing on record the principal directions in which the Association has done good to the public and the profession in the past, and the ways in which it may increase its field of usefulness in the future. There is no doubt that the Municipal Electrical Association supplies a real want, and has abundantly justified its existence. We would, indeed, go further than Mr. MOUNTAIN and express the view that the time has now arrived when the Association should launch out into still deeper waters. A more ambitious career should be mapped out for it by those who have its destinies under their immediate control. To this end a greater degree of permanent organisation may be recommended. With a permanent local habitation, and under the direction of a permanent paid secretary possessing the requisite business and technical ability, the Association would speedily develop into a powerful organisation capable of safeguarding thoroughly the interests of the municipal electrical industries.

OUR readers will not have forgotten the extreme difficulty experienced a few years ago, even by the most skilled manipulators, in reproducing experiments with Hertzian rays with sufficient certainty to serve as lecture demonstrations. Familiarity with the means of producing and detecting electrical waves has now so much increased that, with comparatively simple apparatus, Dr. FLEMING was able to show with ease at the Royal Society's *conversazione* last night a number of the properties of ether waves of about 4in. wave-length. The radiator was simply a pair of brass balls at the end of brass rods, placed in a zinc box open at one end, and connected to the secondary of an induction coil through short choking coils of gutta-percha covered wire. These coils are an important detail, as, if they are absent, electrical radiations are emitted from the connecting wires and terminals of the coil and lead to disturbing effects. The receiver consisted merely of two wires dipping into a small ebonite box of nickel filings, placed in a similar box to the transmitter. The wires from the coherer to the metal box containing the relay and bell must be protected from the waves, although Prof. FLEMING found that the cover of this box could be left open without any disturbing effect. If, however, the connecting wires between the receiver and box are not covered throughout with a conducting sheath sealed into the metal box, they can collect waves and produce disturbance. Prof. FLEMING even experienced trouble when he employed flexible "steam-tight" tubing in place of ordinary lead tubing—probably owing to its electrical resistance being too high.

THE experiments themselves were those mentioned by Prof. FLEMING in our correspondence columns on June 1st. It was interesting to see that waves, which would pass through several dry bricks placed together, were absorbed by a single wet brick, a wet duster, a piece of metal foil, the hand, or even a fairly coarse metal grating. The opacity of insulating liquids with high dielectric constants, such as pure water and alcohol, was clearly shown, as well as a pretty experiment with a block of ice which was transparent only so long as its surface was dry. Tobacco in a

Digitized by Google

dry condition being transparent to the waves, Prof. FLEMING suggested this test as a means of determining whether its contents of moisture exceeded the legal limit. Refraction and total reflection were clearly shown with 60deg. and right-angled prisms of paraffin wax of a size easy to handle, and the concentration of a beam by a wax plano-cylindrical lens was also quite successful. Reflection by sheets of metal, the hand, or a grating parallel to the lines of electric force was clearly demonstrated, and last, but not least, Prof. FLEMING exhibited to a select few the interference experiment (referred to in the letter already mentioned), of splitting a wave into two parts by metal mirrors at 45deg., and passing each through the two sides of a double U-tube of metal, one path being made half a wave-length longer than the other.

OTHER electrical exhibits at the *conversazione* can be mentioned only briefly. Prof. HELE-SHAW and Mr. HAY again exhibited their experiments in stream-line motion analogous to lines of magnetic induction; among which was a beautiful representation of the lines flowing through a toothed armature. They have made calculations and accurate measurements to determine the degree of correspondence between the two phenomena, and promise a Royal Society Paper on their results. Prof. S. P. THOMPSON repeated the curious demonstrations of the "aberration called coma," which he exhibited at the Physical Society last month, and Prof. DALBY's adjustable model to show the difference between a balanced and unbalanced 4-crank engine attracted much attention, the ease with which the piston masses and crank angles can be adjusted being particularly noteworthy. These exhibits vied for the ladies' approbation with a bullet in a leg of mutton, exhibited by Mr. J. MACKENZIE DAVIDSON with the aid of his "stereoscopic fluoroscope," which has undergone some improvements in detail.

ONE of the unsolved problems of the undulatory theory of light is the condition of the ether inside material bodies. This is a problem somewhat apart from that which Lord KELVIN discussed at the Royal Institution recently, when he sought a *constitution* for the ether capable of permitting the passage of light-waves through it, and yet apparently possessing no "drag" when matter moved through it. The experiments of MICHELSON and MORLEY, of LODGE and others, indicate, as clearly as modern experimental science is capable of doing, the absence of such "drag," and hence the difficulty of formulating a satisfactory constitution for the ether, a difficulty which, to Lord KELVIN's mind, appears to be insuperable.

M. G. SAGNAC, however, in the April number of the *Journal de Physique*, has put forward an hypothesis which appears to us so simple and easy of understanding, that we cannot but believe it must have already presented itself to other physicists. The characteristic feature of this method of viewing the question consists in regarding the ether inside material bodies as identical in wave-propagating capacity to the ether in free space. The retardation experienced by a ray of light in passing through a transparent body is then explained by assuming discontinuities of the waves at the surfaces of the molecules themselves, in consequence of which the rays are reflected to-and-fro and from molecule to molecule—the passage being a fortuitous one, the ray struggling, as it were, to find a path through the ether, which it only succeeds in discovering after numerous trials and exceeding great difficulty. The optical length of the path is increased during these wanderings, and accounts for the observed retardation. As in the ordinary wave-theory, the rectilinear propagation of a plane wave follows from the smallness of the molecule, compared to the wave-length. The size of the molecules is approximately of the order $10^{-3}\lambda$, or, if it be J. J. THOMSON's "corpuscles" which are concerned in obstructing the passage of the ray, the size is of the order $10^{-7}\lambda$—dimensions altogether too small to produce any appreciable diffraction effects. Reflection and transmission of light in bodies, as well as transparency and opacity, evolve themselves readily and simply from this fundamental hypothesis, and an expression for the retardation of a plane wave in passing through a thick plate is deduced which corresponds exactly with experimental results. The apparent absence of "drag" in the ether is also fully accounted for.

BUT it is all too simple. It seems unreasonable to expect that a complete and satisfactory wave-theory should be constructed on such modest and simple foundations. Scientific thought has made a very great advance in the present century, in that it has fully recognised that simplicity is not the necessary accompaniment of truth. The Ptolemaic system preceded the Copernican, and the emission theory of light gave place to the undulatory theory—the accumulation of scientific facts has introduced greater complexity into every science, as such, and we must anticipate complex theories in the case of a science whose range is at all extensive. This is brought home very forcibly in the case of M. SAGNAC's new theory briefly sketched above. No sooner is one difficulty brushed aside than another leaps up in its place; in attending to some only of the diseased organs, the others have made themselves more painfully evident. Although the absence of "drag" between ether and matter is accounted for by this hypothesis, we must remember that in other respects the hypothesis is unacceptable. An ether which is unaffected by the presence of gross matter is an anomaly, and is almost inconceivable. There must be some effect due to the loading of the ether by the molecules of matter immersed in it, which would have the effect of increasing the inertia—not the weight, for the ether has no weight—of the ether in the intermolecular, or, as J. J. THOMSON might say, inter-corpuscular space. There is no room for such an effect in M. SAGNAC's theory, and there will have to be considerable trimming of his sails before the barque which he has launched on the troubled waters of ether theories can safely steer clear of the rocks and shoals lying in its way, and at the same time carry on board all the known facts of optics.

THE report of the directors of the British Electric Traction Co. (Ltd.) (an abstract of which was published in our last issue) and the accounts of the company for the 15 months ended March 31st last, indicate a highly prosperous financial condition. The British Electric Traction

Digitized by Google

Co. controls, or is negotiating for the control and working of, no less than 57 tramway undertakings in the United Kingdom, many of which are actually in operation or under construction. Besides this, the company is making arrangements for further development of this important industry by the issue of new capital. Having in view the extremely precarious nature of tramway enterprise in former years, when horse traction was in vogue, it is satisfactory to notice that dividends of 8 per cent. per annum on the ordinary shares, in addition to the 6 per cent. on the preference shares, have accrued from this extensive business, a fact which, should encourage capitalists and electrical engineers to push forward with the development of electric traction in this country.

While referring to the British Electric Traction Co. we may mention that the committee of the Associated Undertakings has recently drawn up a superannuation scheme which bears every indication of financial soundness and equity. It would be out of place here to describe the details of this scheme; they are, however, clearly set forth in a pamphlet drafted by Mr. W. G. Bond, who has had the matter in hand on behalf of the committee. Schemes of this character, by the consolidation of the interests of employers and employed, and by introducing a solidarity into the staff of a business extending throughout the entire United Kingdom, are well worth imitation by other engineering and industrial undertakings.

Society of Engineers.—About 90 members of this Society visited the Thames Ironworks yesterday afternoon in response to the invitation of The Thames Ironworks Co.

Central London Railway.—It is announced that the official opening of this line by the Prince of Wales will take place on June 27, after which date the line will be shut down and re-opened to the public on or about July 2.

Society of Arts Conversazione.—The annual conversazione of the Society of Arts was held at the Natural History Museum on Wednesday evening. The function was very well attended, but, probably owing to the Royal Society's soirée being on the same evening, several of the most eminent members failed to put in an appearance.

Cable Interruptions:—	Date of Interruption.
Latakia—Cyprus	June 21, 1899
Cayenne—Pinhieros	Oct. 11, 1899
Tangier—Tarifa	Jan. 3, 1900
Paramaribo—Cayenne	Feb. 16, 1900
Ceara—Maranham	Feb. 20, 1900
Pará—Maranham	Mar. 2, 1900
Môle-St. Nicolas—Cap Haitien	Mar. 7, 1900

Electrical Engineers (R.E.) Volunteers.—Among the casualties reported with the construction train at Leeuwspruit on the 14th inst. are the following: Severely wounded: 2nd Lieut. H. F. Bigge. Missing: Corporals G. Charlton, Sellon, A. Charlton, Colson, Landon, Pearl, and civilian servant Worcer.——The Corps of Electrical Engineers (R.E.) Volunteers will undergo its training in the Isle of Wight this year.

The National Physical Laboratory.—The Richmond Town Council have resolved "that in the opinion of this Council the proposal to erect a large physical laboratory and engineering shop in the Old Deer Park is highly objectionable." A deputation consisting of Aldermen Burt, Skewes-Cox, Roberts, and Councillors Duncan and Lucas, has been appointed to wait upon the authorities and support the objection.

The Sprague Motor Suspension Patent.—In connection with the case of the Electric Construction Co. *v.* Imperial Tramways Co., judgment on which was given in the Court of Appeal on Monday, and which is reported elsewhere in this issue, it is interesting to note that a decision in the reverse direction as to the validity of the Sprague Motor Suspension Patent was upheld in the United States Circuit Court of Appeals on May 28 in the case of the Sprague Electric Railway and Motor Co. *v.* the Nassau Electric Railroad Co.

The Electrostatic Capacity of a Tore.—In a Paper read before the Société Physico-Chimique Russe, and abstracted in a recent number of the *Journal de Physique*, a method is developed by M. Boulgakoff for calculating the value of a tore of certain dimensions. For a surface generated by the revolution of a disc 3cm. diameter, whose centre describes a circle of 30cm. radius, the capacity was calculated to be 10·8253 electrostatic units. Careful measurement gave, experimentally, the value 10·82, thus conclusively justifying the accuracy of the method of calculation. It is shown as a deduction from the experiments, that a value for v can be obtained which does not exceed 3×10^{10} cm. per second by as much as $\frac{1}{1000}$th.

The Society of Arts Medals.—The Society of Arts Albert Medal for the present year has, with the approval of His Royal Highness the Prince of Wales, President of the Society, been awarded to Mr. Henry Wilde, F.R.S., "For the Discovery and Practical Demonstration of the Indefinite Increase of the Magnetic and Electric Forces from Quantities Indefinitely Small"—the principle on which the invention of the modern dynamo is based. The Society's Silver Medals have been awarded to, among others, the following readers of papers during the session 1899-1900: Sir W. Martin Conway, for his paper on "Some of the Undeveloped Resources of Bolivia," and to Prof. R. W. Wood, for his paper on "The Diffraction Process of Colour Photography."

Cape Town Local Section of the Institution of Electrical Engineers.—The first annual meeting of the Cape Town Section of the Institution of Electrical Engineers was held on May 7. According to the report of the committee of the section, the membership stood at 25, and during the year nine meetings had been held, at which various Papers had been read and discussed. The committee had intended to give an official welcome to the Electrical Engineers (R.E.) Volunteers contingent on their way to the seat of war, but unfortunately it arrived unexpectedly. Other efforts to entertain the volunteers had also to be abandoned owing to the sudden departure of the force for the front. Mr. C. Proctor Banham was re-elected chairman of the section, and Mr. J. Denham honorary secretary. The meeting then discussed "The Cost of Steam Raising."

Liverpool Overhead Railway Co.'s Tramway Extension.—This line was inspected by Col. Yorke and Mr. A. P. Trotter, on behalf of the Board of Trade, on Tuesday, and was opened to the public on Wednesday. The line at present runs from Seaforth to Waterloo—about one mile—the remaining portion to Great Crosby not being complete yet. Ordinary girder rails are used, bedded in concrete, and the streets are paved with granite setts and cubes. The line is worked on the overhead trolley system, the trolley being suspended from bracket poles. Power is generated at the company's main generating station at the Bramley-Moore Dock at a pressure of 1,200 volts, and transformed at Seaforth to the line pressure of 500 volts. The new generating plant consists of a 1,500 H.P. Browett and Lindley engine, driving a British Schuckert 800 kw. generator.

The Ultimate Cost of Bad Wiring.—A correspondent signing himself "Dead Earth," writes in the *Belfast Evening Telegraph* as follows: "We continually hear complaints of the high price the Corporation charge for current. Now this, to a large extent, is a great fallacy, for if the consumer paid only for the current he used he would find his electric bill to be extremely moderate, but, alas! (I am sorry to be compelled to state it) in a large number of cases the poor consumer is paying for current he never uses, it going to earth or leakage." Then follows a just condemnation of cheap and nasty wiring. The "fallacy," however, is the writer's. Cheap wiring is dear in the long run owing to the perpetual cost of repairs and maintenance and the difficulty of making subsequent alterations and extensions. Before the leakage current seriously affected the meter reading, the consumer's house would probably either

Digitized by Google

be burnt down or else have been cut off, as a nuisance, by the supply station engineer.

The Cost of Private Lighting Plants.—The following figures, given in a letter by Mr. G. R. Peers to the *Drapers' Record*, are of some interest. They are for the cost of the electric lighting of a large Manchester drapery establishment for 12 months:—

Comparison of Cost of Electricity from Corporation Supply and Generating Plant in Manchester.

Units consumed in 1893 from Corporation supply, 12,500 = total cost, £260.

1899—Capital outlay on generating machinery, £560.

Lamps installed, 42 10-ampere arcs, and 40 16 c.p. incandescents.

507,000 cubic ft. gas at 2s. 3d.	£57	
Water, oil, waste, and stores	10	
Renewal of brushes and repairs	—	
Depreciation on plant (£560) at 5 per cent.	28	
Interest on capital cost of plant at 5 per cent. on £560	28	
Extra wages for attendance at 10s. per week	26	
	—	£149

Total units generated by own plant during year, 16,700; total cost of generating expenses, £149; equal 2·15d. per unit.

The Royal Society.—The following is a list of the Papers down for reading yesterday: "On the Effects of Changes of Temperature on the Elasticities and Internal Viscosity of Metal Wires," by Prof. A. Gray, V. J. Blyth, and J. S. Dunlop; "On the Connection between the Electrical Properties and the Chemical Composition of Different Kinds of Glass. Part II.," by Prof. A. Gray and Prof. J. J. Dobbie; "On the Change of Resistance in Iron produced by Magnetization," by Prof. A. Gray and Prof. E. T. Jones; "Underground Temperature at Oxford in the year 1899, as determined by Five Platinum Resistance Thermometers," by Dr. A. A. Ramabut; "On the Kinetic Accumulation of Stress, illustrated by the Theory of Impulsive Torsion," by Prof. Karl Pearson; "Lines of Induction in a Magnetic Field," by Prof. Hele-Shaw and A. Hay; "On the Spectroscopic Examination of Colour Produced by Simultaneous Contrast," by G. J. Burch; "An Experimental Investigation into the Flow of Marble," by F. D. Adams and Dr. J. T. Nicolson; and "A Criticism of the Young-Helmholtz Theory of Colour Perception," by Dr. F. W. Edridge-Green.

Owens College Physical Laboratory.—The new physical laboratory at Owens College, Manchester, will be opened on the 29th inst. by Lord Rayleigh. The new laboratory will have a larger floor area than that of any other similar institution in the world, with the exception of the Johns Hopkins and the Strasburg Laboratories. Great efforts have been made to provide an equipment of the most modern apparatus for use in every branch of physical science, and to maintain conditions which would ensure their being used to the best advantage. The research laboratories are to be an important feature of the new buildings, and are certain to attract a large number of students. Another feature is the electro-technical wing, which is to constitute a John Hopkinson memorial, and will be formally handed over by the relatives of the late Dr. John Hopkinson, on the occasion of the opening ceremony. We understand that Dr. C. H. Lees, formerly chief assistant lecturer in the physics department of Owens College, will occupy the post of assistant director of the new laboratories, of which Prof. A. Schuster is the director, and that Mr. R. Beattie has been appointed lecturer in electrotechnics.

Optical Telegraphy.—At a recent meeting of the Elektrotechnischer Verein, after a demonstration of the Zickler ultra-violet wave telegraphy (see *The Electrician*, Vol. XLI., p. 720) had been given by Prof. Strecker, Herr J. H. West described another system of optical telegraphy which, he said, would fulfil almost the same purpose as Prof. Zickler's, except that it does not include a system of calling up. In Herr West's system the transmitting station consists of a strong source of light and a plate of quartz, and the receiving station is merely another quartz plate protecting the eye of the observer. In order to transmit Morse signals, the quartz plate at the sending end is turned through an angle of 90deg. Thus in one position the polarised light will be seen, while in the other position it will not. Messages are kept secret from the ordinary observer, as the beam of light will always appear the same to the naked eye. We do not envy the operators the intense eye-fatigue in trying to pick up signals by the variations of light due to a rocking analyser. All who have tried to quench intensely strong polarised light in this way will know how unsatisfactory a signalling device this would afford.

Incandescent Lamp Standards.—A report on the subject of standard incandescent lamps was presented at the meeting of the American National Electric Light Convention, held in Chicago last month, and contained the following recommendations:—"That the National Standardising Bureau, a bill for the establishment of which is now before Congress, be requested to issue authoritative standards of light to all who should desire them. Pending the establishment of such an institution, 16 c.p. incandescent lamps of 110 volts and 220 volts are to be prepared at the Columbia University, New York City, and will be available to all members of the association at the cost price of production." Attention is called, in the report, to the fact that photometers must be adjusted by rotating the standard lamp, at its rated voltage, in the same place as the lamps to be subsequently tested. The rotation of lamps about a vertical axis is at present considered sufficient, although when lamp filaments are made with more uniform characteristics than at present, arrangements for measuring the zonal distribution might be desirable. It is recommended, also, that greater variations from the nominal wattage of a 16 c.p. lamp than 2·5 watts on either side be not permitted. With respect to the sampling, the testing is recommended of 10 lamps, taken indiscriminately from any barrel, failure of any one lamp to comply with the limits heretofore adopted by the association rendering the whole lot liable to rejection.

The Schäfer System of Wireless Telegraphy.—At a recent meeting of the Physical Society of Frankfort-on-the-Main a description was given of a system of wireless telegraphy, said to be discovered by Herr Bála Schäfer. A sheet of tinfoil is pasted to a glass plate, and the foil is cut into several strips by a sharp knife. It appears that, in ordinary circumstances, there is no absolute electrical discontinuity between the first and last strips, and a resistance of 50 ohms existed in the example cited. As soon, however, as the plate was subjected to the influence of electric waves the resistance rose to 5,000 ohms, but as soon as the waves ceased the original value of 50 ohms was resumed. Herr Schäfer has, up to the present time, been unable to find the cause of this phenomenon. He first thought it might be due to moisture on the plate, but finds that the same effect is obtained in a vacuum. In later apparatus he has replaced the tinfoil by silvered glass, the metal being divided up by several cuts, the sum of whose widths are only a few hundredths of a millimetre. The sensitiveness of the apparatus increases with the width and number of cuts up to a certain point, and then again diminishes. Either a telephone or a Morse inker can be used in the local circuit of the receiving station. It is stated, in the report of the Paper published in the *Elektrotechnische Rundschau*, that experiments were made across the Bristol Channel in the presence of officers of the British Post Office, and that the British Government has decided to make use of the Schäfer system. We learn on enquiry, however, that the latter part of this statement is not correct. Successful transmission is also said to have taken place between the shore and a moving ship in the Adriatic sea up to a distance of nearly 60 miles, a 30 cm. induction coil and a vertical wire 20 metres high being employed.

MEETINGS OF SCIENTIFIC AND ENGINEERING SOCIETIES, &c.

(To-day) FRIDAY, June 22nd.

PHYSICAL SOCIETY.

5 p.m. Meeting in the Rooms of the Chemical Society, Burlington House. Agenda: (1) "Notes on Gas Thermometry," by Dr. P. Chappuis; (2) "A Comparison of Impure Platinum Thermometers," by H. M. Tory; (3) "On the Law of Cailletet and Mathias and the Critical Density," by Prof. J. Young, F.R.S.

TUESDAY, June 26th.

INSTITUTION OF ELECTRICAL ENGINEERS.

9 p.m. Annual Conversazione at the Natural History Museum, Cromwell-road, S.W.

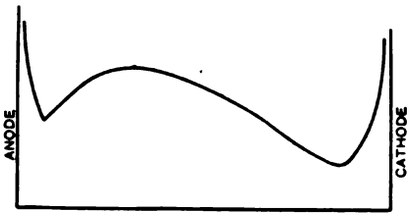
CONTEMPORARY ELECTRICAL SCIENCE.

[Compiled by E. E. Fournier d'Albe.]

Balloon Telegraphy.—An obstacle in the way of telegraphic communication with free balloons has been thought to lie in the impossibility of earthing the receiver. But some experiments made by J. Vallot and J. and L. Lecarme have proved that such connection is not necessary, even at great distances. No attempt was made to send signals from the balloon, on account of the danger of igniting the gas with the exciter sparks. The balloon carried a wire 50 metres long attached to the car, and the wire attached to the transmitter was held up by a small balloon. No attempt at alphabetical signalling was made, the only indicator used being an electric bell. At first the balloon ascended straight upwards, so that the two wires were in one line. This did not interfere in the least with the signalling, a fact which shows that the vertical wire is unable to produce a purely horizontal wave. Signals were received up to an altitude of 600 metres. When the balloon was at a horizontal distance of 5 kilometres, with an increase in the sensitiveness, they were perceived at a distance of 6 kilometres and a height of 800 metres. In conformity with the results obtained by the same authors in their experiments on Mont Blanc, the difference of potential between the sending and receiving stations had no influence upon the signals.

[Vallot and Lecarme, *Comptes Rendus*, May 14, 1900.]

Conductivity in a Vacuum Tube.—The apparent anomalies in the conductivity of rarefied gases are due to a variety of causes which do not come into play in the case of liquids or solids. Fundamentally, the processes of electric conduction are probably the same, and even in a wire inserted in a circuit of different material we have anything but a uniform conductivity along its whole length, owing to thermo-electric complications. Such complications, in the case of liquids, lead to an accumulation of the swifter ions in the



neighbourhood of the opposite electrode. In gases, the current also leads to the concentration of conducting particles at the anode. But this concentration is marked by the constant production of new ions at the cathode, by the activity of the cathode rays in lowering the resistance of the gas, and by heat effects. The production of undiffused ions leads to a large increase of resistance at both the electrodes. Neglecting the heat effects, which cannot be at present precisely determined, the author gives the annexed diagram as a typical representation of the specific conductivities at various points between the anode and cathode. He verifies it by sending a transverse current through auxiliary electrodes.

[J. Stark, *Ann. der Phys.*, No. 5, 1900.]

Irregularity of Liquid Interrupters.—On the strength of some mutographic records of the discharge of an induction coil worked with a Wehnelt interrupter, J. H. West (see *The Electrician*, Vol. XLIV., p. 71) maintained that the interruptions are by no means regular, and that the discharge often fails to take place for three or four successive interruptions. This defect, which is indicated by the unmelodious noise of the interrupter, might be attributed to the spark-gap of the coil rather than to the liquid of the interrupter, especially as the resistance of an air-gap is subject to rapid fluctations. To clinch the matter, E. Ruhmer has taken mutographic records of the sparks in the interrupter itself, both Wehnelt's original and Simon's improved pattern. The results show that both these interrupters are subject to considerable variations in the rate of interruption. The variations amount to 17 per cent. in the Wehnelt pattern and 24 per cent. in Simon's pattern, the excess in the latter being due to currents in the liquid not produced by electrolysis. Besides these variations, the interrupters also fail to interrupt occasionally, or at least to break the current completely. The author counted 16 failures in every hundred in the Wehnelt interrupter and nine in the Simon interrupter. So far, then, Boas's turbine interrupter has a great advantage where regularity is concerned.

[E. Ruhmer, *Elektrotechnische Zeitschrift*, April 26, 1900.]

Revolving Magnetic Flag.—Under this curious name G. Jaumann describes an ingenious apparatus for demonstrating the existence of a magnetic whirl in the interior of a conductor carrying a current. The conductor in question is a beaker filled with mercury, and the indicator is a small magnet attached with one end at right angles to a glass rod running along the axis of the beaker and mounted on pivots. Thus the "magnetic flag" is capable of rotation in a plane at right action to the direction of the current. The beaker is inserted in a tight-fitting copper vessel which furnishes the return circuit and abolishes the external field due to the current. The bottom of the beaker is perforated to admit an electrode which plunges into the mercury. To ensure that only the magnetic whirl inside the mercury influences the motion of the flag, the earth's magnetic field is compensated by suitable permanent magnets, and the glass rod or flagstaff is weighted so as to insure neutral equilibrium even out of the vertical. When the current is turned on, the flag rotates with uniform velocity, the north-seeking pole following the lines of force. The considerable work spent in overcoming the resistance and viscosity of the mercury is taken out of the current, and shows itself in a counter E.M.F. impressed upon the circuit. This counter E.M.F. disappears as soon as the mercury has acquired the angular velocity of the flag. It re-appears, but with the opposite sign, when the flag is artificially stopped, until the mercury itself has come to rest again. The flag rotates whether it is lacquered or left in the bare metallic state.

[G. Jaumann, *Ann. der Phys.*, No. 5, 1900.]

Tuning of Wireless Receivers.—The construction of receivers "tuned" so as to respond to one particular kind of wave only is subject to the difficulty that every receiver yet devised is found to respond more or less to every wave impinging upon it, owing to the excessive damping to which the wave-train emitted is unavoidably subjected. This damping does not, so to speak, allow the proper periodicity of the wave-train to assert itself. A. Blondel describes a system which he believes to possess notable advantages over those of Lodge, Marconi, and other less promising ones. The principle adopted is that of synchronising the frequency of interruption of the exciting coil and of a "monotelephone" attached to the receiver. The group of strongly damped high-frequency waves acts as a simple percussion upon the slowly vibrating telephone, and there would indeed be no difficulty in applying Mercadier's device for multiplex telegraphy to the receiving apparatus. An automatic coherer, such as that of Tommasina, is placed in series with a collecting wire, and in a branch circuit parallel with the coherer is inserted the telephone, a battery shunted by a condenser, and, if necessary, an inductance. The capacity of the condenser is so chosen that the usual relation

$$\left(\frac{2\pi}{T}\right)^2 LC = 1$$

is fulfilled where T is the frequency of charge of the mast-wire at the emitting station. There is then a kind of resonance between the branch circuit and the transmitter. If required, additional receivers with different frequencies can be branched off in the same manner, or they can be attached to special collecting wires. In this manner the same signal station may be made to receive messages from different quarters, and none of these messages can be read by an instrument not tuned to unison in the same manner.

[A. Blondel, *Comptes Rendus*, May 21, 1900.]

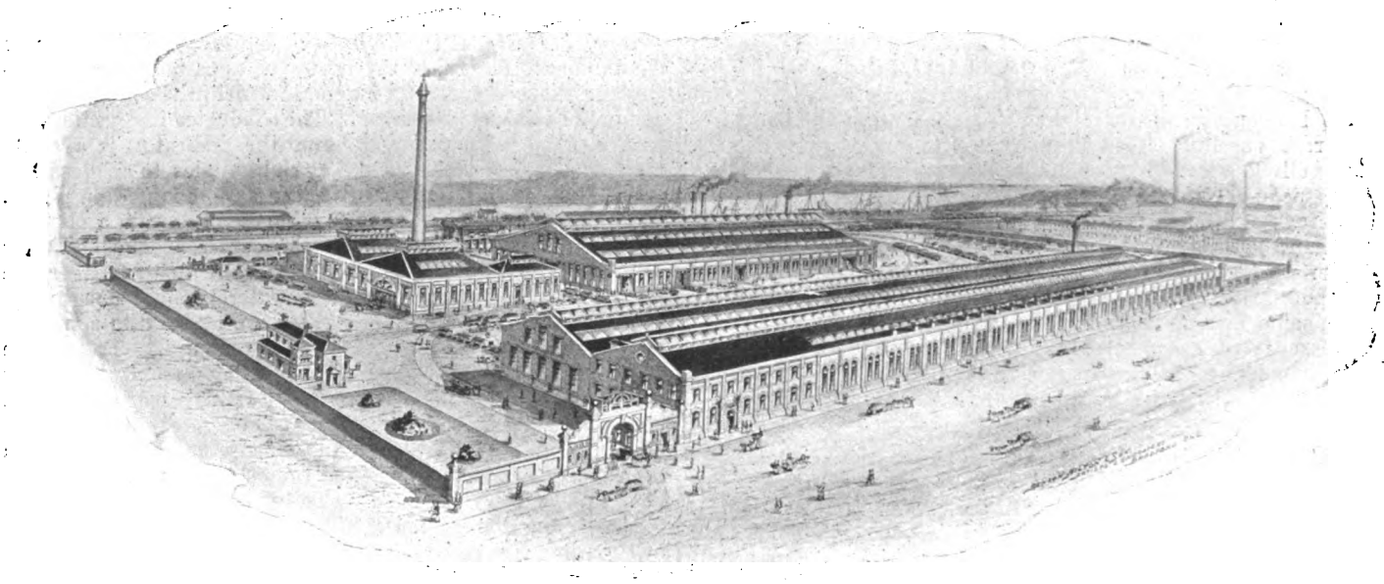
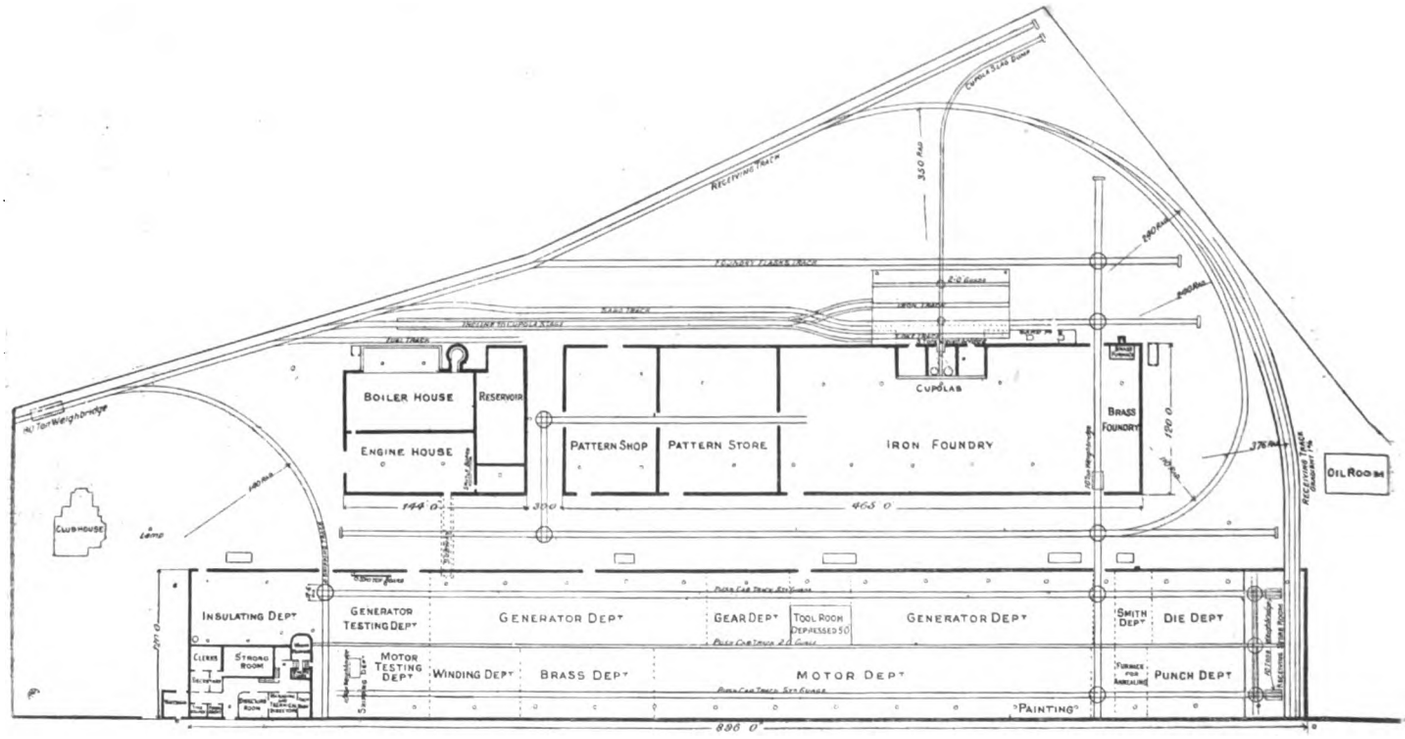
THE NEW WORKS OF THE ENGLISH ELECTRIC MANUFACTURING CO. AT PRESTON.

Organisation.—Our readers who are interested in electric traction are aware that less than two years ago certain gentlemen closely connected with traction undertakings, foreseeing the extent to which the demand for tramway rolling stock was likely to exceed the supply from existing number of the shareholders in this undertaking were equally desirous of embarking in the collateral but much more important work of manufacturing the electrical portion of the equipment required for traction work. At the same time it was perfectly realised that to meet the competition of the



Bird's-Eye View of the English Electric Manufacturing Co.'s Works at Preston.



Plan of the English Electric Manufacturing Co.'s Works at Preston.

shops in this country, even when augmented by American importations, organised the Electric Railway and Tramway Carriage Works (Ltd.), at Preston, and on an excellent site of 14 acres on Strand-road, near the docks, erected a large and thoroughly well equipped plant for the manufacture of car bodies and trucks. These shops, the equipment and management of which were placed in the hands of experienced and competent tramcar builders from America, have been entirely successful both in the quality of their output and in the volume and satisfactory nature of the business done. A enormous American electric shops, with their long experience and excellent equipment for the work, it would be necessary to proceed on precisely similar lines to those which had given our transatlantic competitors their predominant position in this branch of manufacturing. Manifestly to obtain this result the first step was to secure the co-operation of an American engineer and designer of the first rank who could supply manufacturing and engineering experience unobtainable in this country, yet essential to the success of the enterprise. It was at this juncture that, in the course of one of the

Digitized by Google

periodical manias for amalgamation which take possession of our American cousins, the Walker Co., the third of the three great electrical organisations in America, was "consolidated" with one of its rivals, thus practically completing the formation of the great electrical "pool" which controls the industry in that country. The hands of Mr. S. H. Short, the managing director and technical head of the Walker organisation, whose brilliant works dating from the beginnings of electric traction in America, in 1885, is known to electrical engineers throughout the world, were thus left free to carry out a long-considered project of contributing to the further development of the industry on this side of the Atlantic. At a meeting between Mr. Short and some of the future shareholders of the English Electric Manufacturing Co. (Ltd.), an arrangement was made by which the new company was to commence operations on a large plant for the manufacture of electric traction apparatus from his designs and under his patents, and at the same time that he was to join the board as technical director to design the manufacturing plant and take full charge of its engineering and manufacturing organisation. At the end of May, 1899, all the plans for the works had been completed, and orders placed for the most complete equipment of tools and machinery which money could buy or experience suggest for the purpose. On June 14 (just one year from the opening of the finished works) excavation for foundations was commenced, and since that time the work has proceeded without a moment's delay. In this connection we may say that the completion of so large an undertaking within one year from the date of its commencement is not only without precedent even amongst our "hustling" American friends, but even more significant as indicating the aggressive energy with which the future operations of the company will be carried on.

Site.—For the site of the new works the company secured over 12 acres of level ground situated between Strand-road and the Preston Corporation docks on the river Ribble, the factories of the Electric Railway and Tramway Carriage Works being located immediately across the street. The selection of Preston as the site for the works was finally arrived at after a careful consideration of the relative advantages offered by different localities. Situated in Lancashire and therefore in immediate contact with the great producing centres for coal, iron, and other raw materials required, it possesses exceptionally good shipping facilities for the finished product of the works. It is centrally situated with respect to the home market with two great railway systems radiating in every direction, and at the same time in a position where advantage can be taken of the proximity of the great port of Liverpool for export trade to the colonies and abroad. Another and most important reason for the establishment of the works at Preston was the fact that a suitable site could be obtained alongside the Electric Railway and Tramway Carriage Works. The tramcars and trucks manufactured at these works are therefore ready to receive the motors and electrical equipments from the shops of the Electric Manufacturing Co., with the unique advantage of enabling the joint product to be completely equipped and tested before leaving the works; the advantages of this arrangement are obvious.

Buildings.—Of the 12 acres of land embraced in the company's manufacturing site, about 5 acres are under roof. The buildings, which in accordance with the practice of to-day are one storey high throughout, except in the offices, are laid out on the lines of the most modern American engineering works, a steel frame being first erected to carry the cranes and roof structure, and the sides and ends independently walled in. The foundations for the steel stanchions for the buildings themselves and for the machinery in the works are much more solid and massive than is usual for work of this kind. The principal buildings are three in number—the machine shop, with the offices; the foundry, with pattern and pattern storage shops; and the power house. Before entering in detail into a description of the equipment of the works and the method in which the various operations in the manufacture of traction machinery are carried out it is essential that we should note the facilities which are provided for receiving, shipping, and handling material.

Receiving and Shipping Tracks.—By reference to the accompanying plan it will be noticed that all incoming and outgoing goods pass in at the railway entrance over an 80-ton weighbridge. The tracks diverging from the weighbridge are, taken in order—first, the machine shop track, over which all goods are shipped out; second, the fuel track; third, the inclined track to the elevated foundry cupola staging; fourth, the sand track; fifth, the foundry flask track which can be used for storage or relief; and finally, the receiving track, on which will be noticed a side track for the storage of waggons. Following round the large curve of the receiving track it will be noticed that it enters the receiving store room at the rear end of the machine shop, the track at this end being depressed so as to bring the truck platforms level with the machine shop floors. For the handling of waggons within the yards as well as for the railway connection, and in to the yards of the Electric Railway and Tramway Carriage Works, electric locomotives are provided. The works are connected by sidings with the Lancashire and Yorkshire Railway, the London and North Western Railway, and the Preston Corporation Docks.

Machine Shop.—The largest and most important of the buildings making up the works is the machine shop, which in itself is a structure of imposing dimensions, 900ft. in length by 120ft. wide, 85ft. high in the clear, and with 25ft. head room under the cranes. From end to end, throughout the centre of this building, passes a line of double lattice work stanchions which support the roof, the crane girders, and the line shafting. In the general arrangement of the works, and especially in the detailed plans of the machine shop, it has been Mr. Short's chief object to avoid, wherever possible, the handling and re-handling of the various parts of the apparatus during the processes of manufacture. Raw materials delivered at one end of the main building pass through the successive operations always moving in one direction, and emerge at the other end finished and tested apparatus ready for loading upon the railway trucks. Exceptional attention has been paid to the matter of facilitating the progress of the material through the shops by means of powerful high-speed electric cranes supplemented by pneumatic hoists and tracks in every building. Each of the four motor cranes used in the works is arranged to be provided with lifting magnets in order that all suitable material and parts of apparatus made of iron or steel may be picked up and carried to any part of the shop without other manipulation than that of the operator handling the crane. By means of jib cranes and pneumatic hoists the men operating machines will be able to lift into their tools pieces weighing from 1 ton to 2 ton each. Down each bay of the shop is laid a push car track with an additional track in the centre of the shop running between the stanchions which support the counter-shafts, cranes, and roofs. It will thus be seen that in addition to the four large cranes provided in the machine shop there are three tracks running its full length, thus giving seven methods of handling material up and down the shop. To facilitate communication between the various parts of the works a telephone system is provided extending from the offices to all departments. Compressed air at 100lb. pressure is distributed to every part of the works, and used in the operation of pneumatic drills, hammers, &c., as well as for operating the pneumatic hoists.

The machinery throughout the works is operated by electric power from the generating station. The limits to which the principle of sub-division of power into small units could be advantageously extended has been most carefully considered. The resulting arrangement in so far as the machine shop is concerned represents entirely new practice, and is worthy of being described in some detail. As has been stated, a sectional line shaft extending the full length of the machine shop is supported from the line of centre stanchions between the two bays of the shop. The sections of this shaft are driven by individual 50 H.P. motors, direct connected to them by means of a quill shaft and clutch. The 800ft. of shaft is divided into eight sections; any section of the shafting can be driven by its own motor, or the whole can be driven by any one or more motors. All of the machine tools used in both bays of the shop are thus driven from the one line shaft, except in the case of the larger tools, where individual motors

Digitized by Google

are provided. It will be seen that by this arrangement the greatest possible efficiency is secured in the drive of the machinery, since the grouping of the tools of both bays together allows the use of comparatively large and therefore efficient motors, and friction losses are cut down to a minimum.

As will be seen from our illustrations, the machine shop is divided into two enormous bays, one on either side of the centre stanchion. One of these bays will be devoted entirely to the manufacture of traction motors and details of equipment, while the other will be used for the production of heavier machines such as large dynamos, alternators, rotary transformers, &c. In order to obtain a clear idea of the machine tool equipment of the shops, and of the operations which are carried on, the simplest method will probably be to follow the incoming raw material through the various departments through which it passes up to the point of shipment as finished apparatus. The following is a list of these departments, proceeding from the south end of the building:—

Receiving and Store Room.

Die department.
Punch department.
Smith department.
Annealing department.
Painting department.
Motor machine department.
Brass department.
Field winding department.
Motor testing department.
Generator department.
Tool room.
Gear department.
Generator testing department.
Insulating and armature winding department.

Referring to the plan, at the north end of the shop will be noted the receiving and store rooms into which the receiving track passes. These rooms are fitted with divisions and bins for the various materials. The electric cranes in the two bays unload the materials from the railway trucks and distribute them to the various parts of the store room. From this store room the materials are distributed to the various departments of the works as required.

The first group of tools after leaving the store room constitute the punch and die departments, in which the steel discs required for building up armatures, field-magnet cores, &c., are punched with dies into the required shapes. The machinery used in this department is automatic throughout and of the latest pattern. Immediately near to the punch and die departments is a completely equipped smith shop with power-driven hammers, &c., for shaping the steel from which the dies are made. The delicate process of tempering the dies after completion is also carried on at these forges. This department is fitted with a full equipment of standard lathes, shapers, and drill pressers. Worthy of notice, too, are the grinding machines for grinding the dies with flat cutting surfaces, these moving the piece of work back and forth solely while the large grinding cylinders roll rapidly, and at the same time move along their axes at right angles to the movement of the work, thus ensuring perfectly flat surfaces. Next comes the annealing process, where the armature discs are packed into iron cases and covered with sand to exclude the air. The discs are then placed in ovens where they are raised to a dull red heat and slowly cooled, afterwards being passed through the painting machines, which cover them with the thinnest possible layer of varnish. Issuing from the varnish rolls they are dropped on a moving chain bolt which passes them through a drying oven and delivers them in the assembling department to be built up into cores ready for winding.

Moving down the shop we now come to a second railway track entering the machine shop from the foundry. By means of this track the castings of motor and generator frames are delivered directly to the respective departments equipped for their completion. The first process with the motor castings is to place them on the vertical milling machines which face the two halves to form a perfect magnetic joint. Next in line are the radial drilling machines which drill all the holes in are motor frames. After being bolted together the frames the placed on the horizontal boring mills, which finish the bearings for the armature and axle and bore out the frames to receive the pole-pieces. The frames are now completed and ready for delivery to the motor assembling section. Next beside this group of magnificent boring mills are the motor shaft lathes and special machines for grinding the armature shaft bearings. Then come the massive turret lathes for finishing the armature end plates, the commutator heads, and the bearing shells. The next group of tools, comprising lathes, planers, shapers, milling machines, and many special tools, constitutes the brass working department, where the controllers, rheostats, trolleys, commutators, and brush holders are made. Next is the field-magnet winding section, where the motor and generator field-magnets are wound, insulated, and baked, and the armature coils placed on the motor armature cores. The motors and controllers have now reached the assembling and painting department, from which they are delivered to the testing department, where they are subjected to tests for insulation, &c., and run under full and over load conditions for the specified time. After the tests are completed the temperature of each part is taken, and a thorough examination made as to the quality of workmanship, &c. If perfect in every respect the completed machine is taken charge of by the shipping department, where it is loaded into trucks on the shipping track, which enters the building at the opposite end from the receiving track.

The armature winding, insulating, and mica department for motors, dynamos, and alternators is separate from the main portion of the machine shop, occupying a position at the extreme south end of the generator bay. A brief description of the operations which take place in this department will be of interest. The armature coils which are wound or formed entirely by machinery must be thoroughly insulated with mica, paper, and cotton braiding. They must be properly dried, dipped into special varnish, and then baked in order to exclude all moisture. Afterwards they are pressed into exact shape and formed to size so that all coils and windings may be interchangeable. The mica rings and tubes for commutators are moulded under great pressure while being heated. The presses in which this work is being done have their various parts heated by steam pipes from the boiler house to this portion of the machine shop. Nearly all the winding, insulating and mica moulding in the department is done by girls. Its separation from the main portion of the shop obviates the possibility of metallic chips or filings getting into the insulation.

Returning now to the point where the foundry track enters the machine shop, and coming down the *generator* side of the shops, we find the largest and finest tools in the plant for machining and finishing. The generator frames, after coming from the foundry, are first placed on an enormous planing machine to be faced at the joints. The bed of this planing machine is 24ft. long, and will receive castings up to this length. This tool weighs over 75 tons, and is driven by its own separate motor. The next tool—the largest in the works—is a boring mill, swinging 24ft., used to bore out armature heads to receive the engine shafts, to finish the armature end rings for large generators, and to make the large commutators for these machines. This mill weighs over 100 tons. Next comes a universal boring and milling machine, which, while not so heavy as the boring mill last mentioned, occupies more room, its table flush with the floor being 24ft. square. Along one side of this table travels an upright pillar about 10ft. high. To this pillar is attached a spindle, which can be moved to any position, vertical or horizontal, within the limits of the tool. Generator frame castings are placed upon the table of this machine and all the holes being bored, surface milled—in fact all the remaining machine work—is finished without moving the casting. For the armature heads of large dynamos and alternators portable slotting machines are provided, each with its own motor, to cut the keyways for the engine shafts and the dovetailed slots for fastening the armature laminations. The machine work on the generator frames is now finished, and the material next proceeds to the assembling department opposite the shipping track, where they are erected for test, each generator being thoroughly tested for insulation, output, temperature and commutation. In the testing room there is arranged a complete switch board about 48ft. long, with an assortment of testing instruments of wide range. In the testing department live steam is provided from the boiler house, so that complete engine-dynamo sets can be fully tested. Midway down the generator bay are located two important departments, the tool room—sunk 4ft.

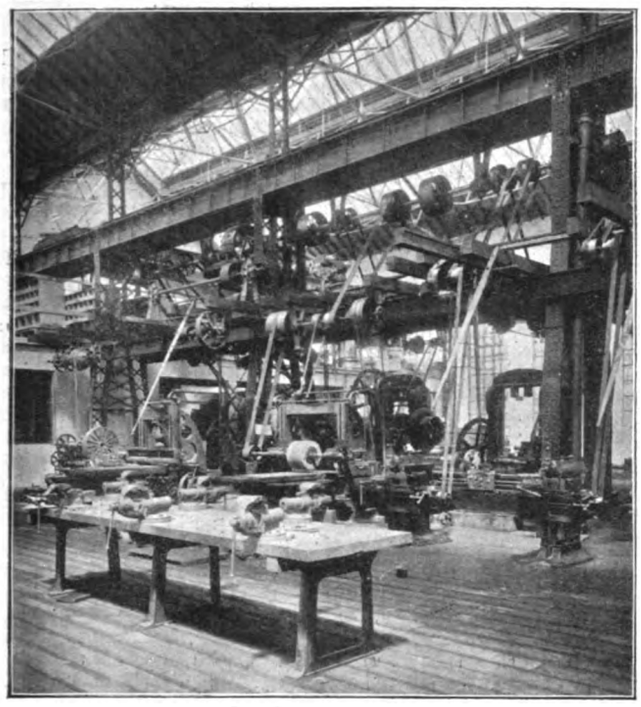
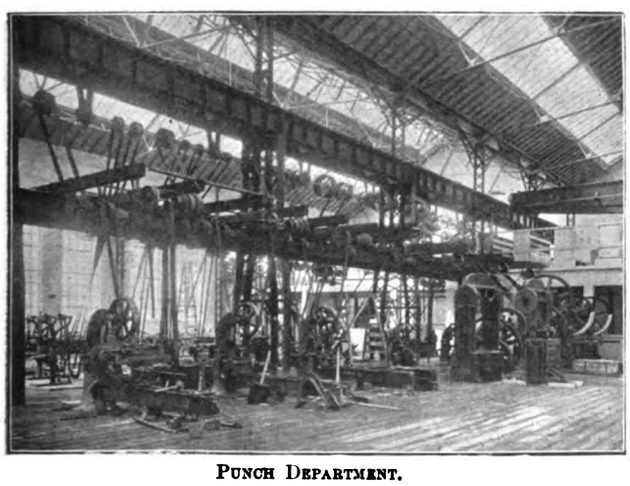
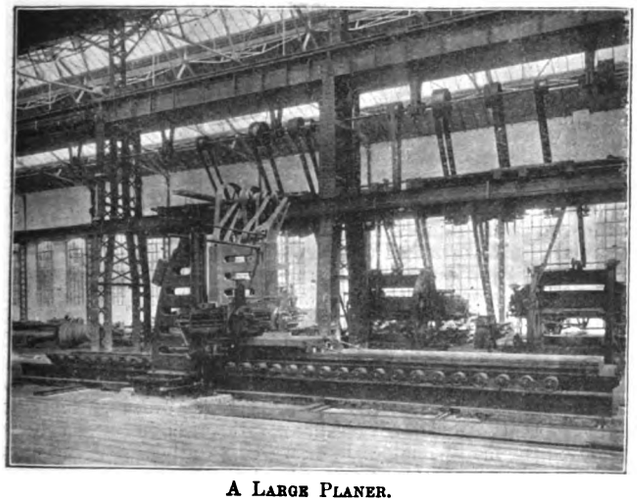
below the floor level so as not to interfere with a clear view of the shops—and the gear cutting department. In the latter is comprised a group of special tools by which all the operations involved in he complicated and tedious operation of cutting the gears are performed automatically and with absolute precision.



DIE DEPARTMENT.



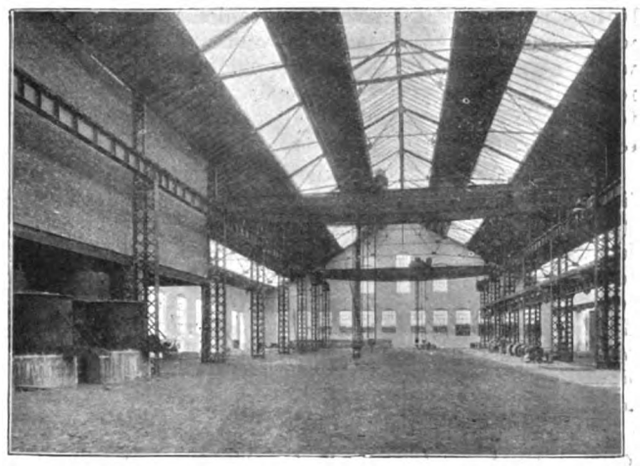
PUNCH DEPARTMENT.



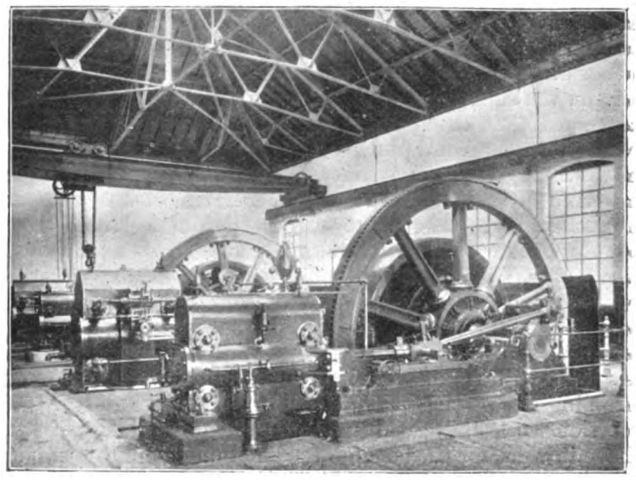
A LARGE PLANER.

Offices.—In the south-east corner of the machine shop building are located the offices on the ground floor, the engineering department occupying the first floor with a thoroughly equipped laboratory for testing all materials entering into the finished product. The drawing offices and a complete photographic department are also located on this

WINDING MACHINES.



IRON FOUNDRY.



POWER HOUSE.

floor. Both the offices on the ground floor and the engineering department are provided with large fireproof strong rooms for books and drawings. On the second floor the company has provided club rooms, consisting of reading rooms and library, dining room and kitchens, for the use of the works staff.

Foundry.—The foundry building is parallel with the machine shop building, with a space of 60ft. between the two. It is 465ft. in length and 120ft. wide, and is equipped with two 30-ton and one 15-ton electric cranes. In this building are contained the iron foundry department, the brass foundry department, the pattern shops, and the pattern storage shops. Two cupolas are provided for moulding iron, and there are five brass furnaces for making brass parts. In both the brass and iron foundries the machine tools provided are driven by independent motors. The pig iron and coke for charging the cupolas is delivered directly from the railway tracks upon the lift cupola staging, on the same level as the cupola charging doors.

Power House.—The power house is at the south end of the foundry with a clear space of 30ft. between the two. It is 144ft. long and 120ft. wide, and is divided into a coal storage room, boiler room, engine room, battery room, and reservoir. The boiler room contains at present three 500 H.P. Lancashire boilers, with ample space to receive an additional three boilers of the same capacity. A Green's economiser is provided together with the necessary boiler feed pumps. The engine room at present contains two cross-compound Corliss engines each direct connected to a generator of 400 H.P. capacity. There is, therefore, 800 H.P. available at the present time with a possible over-load capacity of 25 per cent. Space is left to receive a 1,000 H.P. unit, which will shortly be installed, and the generator for which will be made at these works. The battery room contains a 500-volt chloride accumulator set which is used for supplying light and power throughout the works at night when the power plant is shut down. The reservoir, with a capacity of 60,000 gallons, receives its supply from an elaborate system of roof drains. A cooling tower is erected over one portion of the reservoir.

Lighting and Heating.—All the buildings and grounds are lighted most thoroughly, arc lamps being used for the general lighting, with incandescent lighting suitably arranged for the individual tools. The heating and ventilation of the buildings is amply provided for, so that the temperature can be kept uniform at any point from 60°F. to 70°F. throughout the year. In the offices the direct radiating method is used, while for the shops the hot air system is employed, accomplishing the double purpose of providing not only for heating but for an adequate supply of pure air at all times.

Other Arrangements.—Within the grounds there has been erected what will be known as the directors' club house, provided with a dining room, kitchens, bed rooms, &c., for the accommodation of the directors and their friends while remaining over night at the works. Special attention has been paid not only in the laying out of the plant itself but in other directions for the comfort and means of entertainment of the workmen in the shops. Alongside the foundry it is arranged that extensive bathrooms will be erected, provided with hot and cold plunges, &c., and in which each of the men employed in the foundry will have his own special locker reserved for his private use. A portion of the company's funds is being devoted to the erection of a large group of comfortable workmen's dwelling-houses upon a site close to the works. It is also intended to erect a large club-house with gymnasium and reading rooms, &c., for the men. In this connection it may also be added that the directors of the company, recognising the important part in which the young engineer with a fair technical education and a sound practical training has played in the building up of the industry in connection with the great German and American companies, have in view, for the benefit of such young engineers employed at the works, the delivery of a regular course of lectures on electrical engineering subjects throughout the year, this being a matter to which Mr. Short himself attaches the greatest possible importance as a factor in the continued future success of the undertaking.

THE MUNICIPAL ELECTRICAL ASSOCIATION, PRESIDENTIAL ADDRESS BY MR. A. B. MOUNTAIN, AT HUDDERSFIELD.

In presenting to you my Presidential Address, I avail myself of the opportunity of very sincerely thanking you for the great honour you have done me in electing me your President. I would remind you that this is the fifth Convention the Association has held, and while reminding you that the Association is only five years old, I feel it will interest you if I briefly give you its history, and review some of the work it has already accomplished. Many present may remember that the Board of Trade proposed in 1895 to issue new regulations for controlling the supply of electricity; the engineers of the various municipalities affected met together, and by combined efforts were enabled to persuade the Board of Trade to modify considerably the regulations which were finally issued in 1896. The engineers who were in consultation while the Board of Trade regulations were under consideration, decided to form this Association, feeling that by combination they would be stronger and better able to bring those interested in municipal electricity supply undertakings together for the purpose of interchanging ideas and experiences, and if necessary take action to further or protect the interest of the undertakings in their charge. The Association at its first meeting had only 24 members who were electrical engineers, being permanent officials of municipalities. Mr. Arthur Wright was elected the first President, and the address he delivered to the Association at its first convention, held in London in 1896, clearly outlined a programme of most useful work which the Association had before it; many of the subjects mentioned in that address have had your consideration, and I believe that the discussion of these matters by the engineers, chairmen, and other members of electricity committees has very largely assisted to promote the process and achieve the results which have been obtained. But since the Association was first formed it has grown year by year in the most satisfactory manner: there are now 74 committee and 84 electrical engineer members, three associate members, and 57 associates. The work accomplished by the Association in the past has, I feel certain, been very much appreciated by the Local Authorities interested, and although we may with a certain amount of pride look back upon past achievements, yet the future work of the Association must be of still more importance to all those interested in electricity supply works owned by local authorities.

One of the first subjects discussed by the Association was the control of both the gas and electricity undertakings by one committee. In 1896 several corporations owning both undertakings, had placed them under the charge of one committee, although it was even then recognised that the work was quite of a different character and that the departments must be in a manner competitors; now with very few exceptions the electricity supply is controlled by a special committee, and judging by the progress of both departments during the last few years, it would seem conclusive that the healthy competition has been in the interest of both undertakings. At our first convention two or three corporations had attempted to increase the pressure of supply to consumers and the pressure usually delivered was 100 volts or 110 volts, now it is quite unusual to find any three-wire system delivering a supply with a less pressure than 200 volts or 220 volts; in some cases the declared pressure is 250 volts. It is interesting to think of the enormous saving in copper which this increase in pressure has effected; indeed it would have been impossible for many of the municipalities to have extended their undertakings to any great extent without the alteration of pressure, and the saving of capital has no doubt in a great measure assisted the achievement of the magnificent results which have been obtained. One of the subjects discussed by the Association in 1896 was the question of extension to outlying districts. It largely influenced those members who attended our first convention to appreciate the fact that the residential lighting was worth cultivating, and that the best way to obtain it was to extend mains as rapidly as possible to all the outlying residential sections of a town, and I consider the rapid increase in the demand for electricity is largely due to the spirit of enterprise exhibited by municipalities in encouraging a demand rather than waiting until the demand necessitated the extensions. The consideration of wiring regulations which would be applicable to the whole of Great Britain was discussed at our first meeting, and has since occupied the time of the Association considerably. The rules which have been prepared by the Institution of Electrical Engineers, embodying the views of this Association, are of very great value. Time has not, however, removed the man who does jerry work, indeed it seems as if those workmen who are fit for nothing else become infatuated with wiring, and are really the cause of the bad work which is being done in so many towns. One way out of the difficulty would be to organise a system of examination in connection with our Association, so that good men with a knowledge of their work could obtain a certificate, this would, I am inclined to think, check the engagement of

Digitized by Google

unqualified men, and if the certificate could be withdrawn upon conclusive evidence of bad workmanship it would add to its value. I believe this system would be much appreciated by the better class of workmen, and there would be no great difficulty in organising a system such as that suggested, which would weed out the incapable men. Perhaps, however, some may think it necessary to go further and weed out some of the incapable wiring contractors. Another subject which has been very freely discussed by the Association is the supply of electrical energy for tramways and the advantages of combination over separation, the conclusion of the Association was that municipalities could combine, such combination would tend to reduce the cost of production of energy for both the lighting and traction. Although it is perhaps early to draw conclusions it is interesting to notice that the cost of production in those works where a combined supply is generated is enormously reduced, and that the committees have in some cases been enabled to materially reduce the price of energy to the consumer of electricity, and although there are three municipalities who, having had the opportunity of combination, have preferred entirely separate works, on the other hand it is pleasing to find that 45 have accepted the views of the Association. As an instance of the value of combination, I would remind you of the special meeting of the Association, held in January, 1897, to consider the subject of fire risks. Owing to fires taking place at two of the London companies' works, the fire insurance companies increased the rate of insurance throughout the country from about 5s. per cent. to about 15s. It was pointed out at the meeting that our works consisted of brick and iron, and that fire insurance was unnecessary, therefore the result of our meeting was, that many corporations who had insured discontinued to do so, and the companies very soon afterwards reduced their premiums.

The formation of the defence fund, for resisting the patent action brought by Mr. Rucker against the London Electric Supply Corporation for the use of the alternating-current system of electricity supply, is another instance of the success of combination, individual action would almost certainly have resulted in failure.

To endeavour to touch upon even all the important work of the Association during the last five years, would be impossible in the time at my disposal, but when one contemplates the progress of the various undertakings, the questions and difficulties involved can more easily be appreciated. When we held our first convention there were very few engineers responsible for works having 50,000 lamps connected to the mains, and the output of very few generators exceeded 300 kw.; owing, however, to the constantly increasing number of lamps connected year after year, it has become necessary to adopt larger units of plant, and now generators having an output of 1,000 kw. are quite usual, in fact in many towns it has been found best to take out generators of small size and replace them with plants of very much greater capacity; this has entailed a large waste of capital, and I am inclined to think the Association might well devote its time to the consideration of the size of plant which should be adopted for new works and extension of existing ones. Unfortunately we are very much in the same position as gas works were 25 years ago, we are constantly extending without being able to form any very correct idea of the ultimate size of our works, but with the experience we have had, and with the history of gas before us, it cannot be very difficult to arrive at some useful figures. I would suggest as a moderate figure 15 8 c.p. lamps per head of the population of the area supplied; this would mean that a town having a population of 100,000 would ultimately have approximately 1,500,000 8 c.p. lamps connected to its electricity works. If we disregard for the moment the energy which will be required for driving motors, tram cars, and for many other purposes, which we should largely depend upon to find employment for our machinery during the day-time, and which would not materially increase our maximum load, we find that to supply energy to these lights, assuming one-third to be in use at the same time, we shall require, including spare plant, not less than 20 1,000 kw. generators. This would be an unnecessarily large number of generators, and undoubtedly much more economical results would be obtained by employing 10 generators having an output of 2,000 kw. each. One can only earnestly hope that when the demand for larger units arises our manufacturers of electrical plant will be in the position to supply thoroughly reliable machinery.

You will agree, I feel sure, that I have not in any way magnified the work before us, and I hope that we shall be able, by careful consideration and mutual exchange of facts and experience, to so arrange our works that extensions will not again necessitate the radical alterations which have had to be made in the past at such great expense. When we consider the probable growth of our works, one is forced to think seriously of the various systems in operation and endeavour to ascertain the probable alteration or extension which will be necessary to meet the demand for energy in the future. Simplicity is, I think, the important point we should keep in view: it means reduced capital expenditure, reduced works costs, and reliability of supply. I think the future demand in any town having a population exceeding 75,000 will necessitate the erection of generating works outside the central or densely-populated portion of the town, and that such works will, if the town has a continuous current supply, generate alternating current, either single, two or three phase, which will be converted to continuous current in suitably situated sub-stations, if, however, the town has a single-phase alternating-current system, I think it will have a distinct advantage over its neighbours having continuous current in the fact that it will have a less complicated system, the capital expenditure upon which should be less, the cost of distribution due to the saving of labour should be lower, and the reliability of the system greater unless accumulators are employed upon a large scale. The facts and figures at present obtainable relative to two and three-phase alternating-current systems are not, in my opinion, sufficiently proved to be of much value, and we should watch with the greatest interest the results of some of the systems now being installed. In my opinion, the complications completely outweigh any advantage which two or three-phase systems may have over single phase. We are, I think, too much inclined to follow fashions which can usually be traced to individuals who are in some way interested, and as engineers we should think for ourselves and apply the facts and figures we may obtain to the local conditions we have to deal with, and must not let our engineering enthusiasm make us forget that we have to put down works for distributing electrical energy suitable for all purposes, at the lowest possible cost to the consumer.

During the last and present year much has been heard upon the subject of municipal trading, and the welfare of our electricity supply undertakings are largely involved. It would seem, however, that the sins of local authorities are those of omission, when one considers that provisional orders for electric lighting have been granted to above 300 local authorities, and that only about half are beyond the period of consideration, it must be granted that enterprise is being seriously retarded, and that the idea of obtaining an order and then waiting Micawber-like for something to turn up is neither in the interest of the would-be consumers or the industry, and it can scarcely be surprising to find Parliament considering the granting of powers to companies to supply over large areas and also contemplating competition. There are, however, two strong factors impeding electrical enterprise in the areas of small local authorities, both of which are having the attention of the Council of this Association. The first is that no period being allowed for this construction of works necessitates an immediate payment if interest on capital and sinking fund contributions; the second point is that the period of 25 years allowed for the repayment of capital is unnecessarily short and increases the annual proportion of the sinking fund. The consequence is that some local authorities anticipating loss by the department during the first year or two are anxious to avoid the risk of adding a burden to the rates. I am, of course, aware that this is an excuse and not a solid reason for delaying the commencement of the work for years, and one can scarcely understand why the smaller local authorities who have obtained powers at considerable expense should not have proceeded with the work; their want of enterprise has, in my opinion, brought into existence the larger companies who propose supplying electricity over extended areas. A combined effort to alter the present regulations of the Local Government Board and obtain, if possible, a longer period for the repayment of loans and also a period for construction of works can only be productive of good results, and will certainly enable many councils who are now hesitating to at once put down works and develop the supply of electrical energy for all purposes. It would also have another beneficial result in the fact that it would remove the temptation to reduce the initial capital expenditure by putting in very small plant unsuitable for the works in a few years time, but by the employment of which it may be possible to avoid a loss at the commencement.

While one is forced to the conclusion that the want of energy of many of the smaller local authorities is likely to produce unfortunate results, it is a pleasure to review the general progress made by electricity supply undertakings, and the following figures representing the capital expended upon municipal and companies' works in the United Kingdom are most interesting:—

	1895.	1896.	1897.	1898.
Municipal	£1,772,323	3,392,229	4,662,909	6,979,150
Companies ...	£4,335,357	5,370,134	6,338,744	7,996,591

I am sure our consumers will be interested to hear that the average cost of producing the unit of electrical energy, exclusive of capital charges, is being reduced year by year, and in municipal works was, during 1898, 2·12d. per unit as against 2·7d. per unit in companies' works, and that the average price obtained by municipalities during the same year was 4·35J. per unit as against 5·51d. per unit obtained by companies. These results must be considered highly satisfactory and it is interesting to notice the causes of the reduction in the average works costs. The chief reason for the reduction of costs is due to the reduction in the selling price. This has induced consumers to use more energy per lamps fixed. The second important factor is the more general use of electric motors, which has helped very largely to increase the quantity of energy sold, and has found employment for a portion of our plant during the day-time. The supply of electricity for tramway purposes has also materially

Digitized by Google

assisted the load factor, and has consequently reduced the average cost of production, and as the demand for energy for motive power and tramway purposes is developed so will the cost of production be reduced.

Another opportunity of improving the load factor seems fairly near realisation—that is, the charging of accumulators for motor cars. When considering the various types of motor cars at present upon the market, one is inclined hastily to imagine that electricity is of little use, because with accumulators the length of run is limited to about 40 miles with one charge, and that the difficulties of charging will impede its application. These difficulties disappear if one thinks of the real commercial use which will certainly be made of motor cars. Tradesmen require something reliable for conveying their commodities to various points—usually within a few miles of their premises—and do not require to cover more than about 20 miles per day. For these purposes the electric motor car is most suitable, and the fact that its propelling machinery has no reciprocating parts should add to its reliability and reduce repairs, and if municipalities will arrange charging stations in convenient positions such cars should be speedily adopted, and if the charging is done during the night and early morning the energy used could be supplied at an exceedingly low price, and would still further reduce the average cost of production. The long distance motor cars using petroleum would still for the present appear to have an advantage over electricity owing to the difficulty of charging in out-of-the-way places. In Edinburgh and in other places, motor cars are running in competition with tramways, and one is bound to consider what competition will mean. Motor cars running upon the ordinary road escape the heavy expenditure required for the permanent way of an electric or steam system of tramways, and consequently, in a district having a scattered population unable to support a frequent service of cars, would have an immense advantage in the fact that the capital charges would be very much reduced. This is, in my opinion, an extremely important point, as the financial charges upon a tramway undertaking frequently represent from 25 to 40 per cent. of the total expenses, and it is not at all unusual to find this important item neglected when the cost per car mile is being discussed.

The last subject I will mention is the municipalisation of the telephone system. The Association and the Council have devoted considerable time to the consideration of this subject, and now that Parliament has granted powers to local authorities to municipalise the local system there should be an immediate effort made to make the telephone more popular. This can, I think, only be done successfully by the local authorities, who cannot help being keenly interested in anything which aids or adds to the convenience of its residents. They would undoubtedly be able to give a more efficient and cheaper service than that at present in existence. It is sincerely to be hoped that Corporations will assist the Post Office to develop the service, and will not be either dismayed or delayed by the difficulties which may appear, and which will vanish as soon as a few Corporations have their systems in operation. In conclusion, I regret that, owing to the amount of work before the Association, it is impossible for me to touch upon many very interesting subjects which I should otherwise, had time allowed, have thought it desirable to bring before your notice.

BOOKS RECEIVED.

ELECTRICITY WORKS ACCOUNTS.

Liverpool Municipal Electric Supply Works.

The two accounts which we analyse this week are both interesting examples of the effect of a combined traction and lighting load on the costs of electricity supply. The period of working covered by the Liverpool accounts for 1899 is the first to show the full influence of the tramway load on this undertaking.

In 1898, of the total output of 2,915,695 units sold, 210,492 units or 7·22 per cent. was supplied for public lighting, and 104,815 units or 3·6 per cent. for traction purposes. In 1899, however, out of the total output of 5,729,477 units sold, the tramways took 1,888,728 units, or no less than 32·9 per cent., while the proportion of 201,574 units or 3·5 per cent. was taken by the public lamps. It will thus be seen that to the tramway load was not only chiefly due the splendid advance of 96·5 per cent. in the output of 1899 as compared with 1898, but also the large load factor of 12·7 per cent., as compared with the 9 2 per cent. of the previous year, 1898.

The increase in the lamp connections of nearly 29 per cent. is a most healthy sign for the future.

The costs column shows that full advantage has been taken of the favourable alteration in the conditions of output and load factor. We are happy in being able to record a material diminution in all the items of expenditure, notwithstanding the fact that the 1898 costs were already most satisfactory. At present the results are so uniformly excellent that we are unable to single out one feature from the rest as calling for special commendation.

With a total revenue from all sources of no more than about 3d. per unit, the ratio of costs to revenue of only 42·9 per cent. and a working profit of £41,536, representing 6·11 per cent. on the mean capital, are most excellent results in every way.

Bradford Municipal Electric Supply Works.

Although the proportionate increase of the traction load at Bradford was nothing like so large as at Liverpool, yet both the output and the load factor of 1899 at the former place made an advance but little less striking than in the first undertaking noticed in our comments, while the financial results are even better.

Comparing the position of the Bradford undertaking in 1899 with that in 1898, it will be noticed from our figures that the total equivalent lamp connections had increased from 94,255 8 c.p. lamps to 132,631, or by no less than 40·7 per cent. The output also shows the splendid advance of 70·2 per cent. As a result of the large increase in the motor and traction load on the station, the load factor has been greatly benefited, having risen from 10·2 per cent. to 13·7 per cent. In 1898 the output sold for traction was 202,019 units or 14·2 per cent. of the total sold, while the output to the public lamps was 82,291 units, representing 2·27 per cent. of the total. In 1899 the tramways supply was 618,282 units, being 25·6 per cent. of the total output; the motor load called for a supply of 463,630 units, or 19·2 per cent., and the public lamps for 59,004 units, or 2·44 per cent. of the total.

As in the case of the Liverpool undertaking, the effect on the costs of the large increase in the output and load factor has not been missed. The excellent total costs figure of (1·61d. per unit) of 1898 has fallen to 1·18d., and not only has the total revenue also been reduced to 2·9d. per unit, but the working profit has increased.

The costs column shows that all the chief items of expenditure have diminished excepting the fuel charge. The slight increase in this department was to be expected, in view of the low figure of the previous year, and of the coal prices during the period. Nevertheless this item, and indeed all the other items of works costs, including the management of property charges, present figures well below the average of previous practice, even considering the order of the output and the favourable load factor.

LIVERPOOL—REMARKS.—*a* Of which 104,815 units were supplied to the tramways at 1d. per unit. *b* Includes £15,096 balance of renewals fund account. *c* Separate items not available as the concern was purchased in 1896 for £400,000 in addition to £36,474 being capital spent by the company but not included in the share capital. *d* Over-expended. *e* Includes £437 from tramways. *f* Being £21,818 from sales and repairs less £18,954 wages and material. *g* Includes £356 to insurance and £193 certification of meters. *h* After deducting £5,895, cost of changing pressure of supply. Out of this £2,555, £1,000 is contributed to the City fund. *i* After April 1, 1899, the charge was 4d. per unit. *j* After April 1, 1899, the charge for power was from 2d. to 1d., and for public lighting 2d. per unit. *k* Includes 1,883,728 units sold for tramways. *l* Being maximum supply given at Christmas. *m* On maximum demand system 2d. for first 3,000 units per quarter and 1d. per unit in excess thereof. For tramway supply the charge is 0·9d. per unit. *n* Includes £19,521 balance of renewals fund account. *o* Includes £7,362 from tramways for energy supplied. *p* Includes £355 to insurance and £522 certification of meters. *q* Contributed to the City fund.

BRADFORD—REMARKS.—*a* Includes 202,019 units for tramways. *b* After deducting depreciation on machinery and mains. *c* Includes £1,174 to public lamps. *d* Over-expended. *e* Includes £669 to incandescent lamps for free supplies, £89 to insurance, and £698 to bank interest and commission. *f* Subject to 2½ per cent. discount within two months. *g* Includes £2,032 on public lamps. *h* Includes £257 on lamps, £279 bank commission, and £124 insurance charges. *i* Includes 1,275,214 units for private lighting, 463,630 units for motive power, and 618,282 units for tramways. *j* Per cent. to mean capital less depreciation.

The Electrician.

The Oldest Electrical Journal (established as a weekly Journal 1861—1878

Published every Friday, Price Sixpence; Post Free, Sixpence-Halfpenny.
Editorial Publishing and Printing Offices,

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.

Telephone: 949 Holborn. *Telegrams:* "ELECTRICIAN NEWSPAPER LONDON."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed* "*Coutts and Co.*"

All Editorial letters to be addressed to THE EDITOR.

All letters for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer as evidence of good faith. No notice whatever is taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices, as above*

Subscription Rates.—The Rates for Subscriptions to "THE ELECTRICIAN" are as under:—

	Year	Half-Year	Quarter	
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.	Post free, payable in advance.
Postal Union	30s. 0d.	16s. 0d.	8s. 0d.	

New Volumes of "THE ELECTRICIAN" *commence in April and October.*

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.** *This statement is guaranteed.*

Advertisement Rates, &c., forwarded on application to the Publisher.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Office not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday. Wrapper Advertisements by Wednesday morning.*

OFFICIAL ANNOUNCEMENTS, AUCTIONS, *and* SMALL ADVERTISEMENTS *accepted up to 6 p.m. on Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of THE ELECTRICIAN" *Printing and Publishing Company, Limited. The well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works at present consists of—*

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. ELTON YOUNG, M.I.E.E. Price 10s. 6d., post free; abroad 11s.

THE STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By Messrs. H. K. C. FISHER and J. C. H. DARBY. Price 6s. net; abroad, 6s. 3d.

BIBLIOGRAPHY OF X-RAY LITERATURE AND RESEARCH. Edited by C. E. S. PHILLIPS. With an introduction on the history of Crookes Tube and Röntgen Ray work, and a chapter giving "Practical Hints" on the subject.

THE POTENTIOMETER AND ITS ADJUNCTS. By W. C. FISHER. Price 6s., post free.

LOCALISATION OF FAULTS IN ELECTRIC LIGHT MAINS. By F. C. RAPHAEL. Price 5s., post free.

MOTIVE POWER AND GEARING. By H. TRENCHARD CARTER. Price 12s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. WILKINSON. Price 12s. 6d., post free.

ELECTRICAL LABORATORY NOTES AND FORMS (Elementary and Advanced). Arranged by Dr. J. A. FLEMING, M.A., F.R.S. Printed particulars on application.

ELECTROMAGNETIC THEORY. By OLIVER HEAVISIDE. Vol. I. Price 12s. 6d., post free 13s. Vol. II. Price 12s. 6d.; post free, 13s.

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING. VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. NEW EDITION. Price 12s. 6d., post free. VOL. II:—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. FLEMING, M.A., D.Sc., F.R.S. New Edition. 93 original illustrations, price 6s

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. EWING, M.A. New edition. Price 10s. 6d., post free.

ELECTRIC MOTIVE POWER. By A. T. SNELL. 10s. 6d. post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. WEYMOUTH. Price 7s. 6d. post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By GILBERT S. RAM. Price 7s. 6d., post free.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. GEIPEL and H. M. KILGOUR. Price 7s. 6d. net, post free 7s. 9d., abroad 8s.; large-paper edition, 12s. 6d., post free. New edition in the press.

"THE ELECTRICIAN" PRIMERS. In Two Vols. Paper covers, 2s., post free 2s. 2d. each; strong cloth 2s. 6d., post free 2s. 9d. each. Single Primers 2d., post free 2½d.

WIRELESS TELEGRAPHY: SIGNALLING ACROSS SPACE WITHOUT WIRES BY ELECTRIC WAVES. By Dr. O. J. LODGE. New Edition. Price 5s. net.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING, ELECTRIC TRACTION, TELEGRAPHS, TELEPHONES, &c. A. C. CURTIS-HAYWARD, B.A. To January, 1900. Price 3s. 6d., post free.

CARBON MAKING FOR ALL ELECTRICAL PURPOSES. By FRANCIS JEHL. Price 10s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d., post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 3s. 6d., post free.

FULL CATALOGUE POST FREE ON APPLICATION.

"ELECTRICIAN" SERIES FORTHCOMING BOOKS.

THE ELECTRIC ARC.—By Mrs. AYRTON. This work is in the press, and will contain an historical sketch of the early experiments on the electric arc, as well as the important results of recent research.

PRIMARY BATTERIES.—A work on this subject will shortly be published bringing the theory and practice of the Primary Battery up to date. The book will be fully illustrated.

SECONDARY BATTERIES.—By E. J. WADE. Fully illustrated. The Author in this work will deal briefly with the theory and fully with the chemistry, design, construction and manufacture of secondary batteries or accumulators.

"THE ELECTRICIAN" WIREMAN'S POCKET-BOOK.—Edited by F. C. RAPHAEL. "The Electrician" Company will shortly publish a valuable pocket-book for the use of those engaged in wiring work, both external and internal.

THE TELEPHONE.—By DANE SINCLAIR and F. C. RAPHAEL.

SPECIAL NOTICE.

NOW READY.—Vol. XLIV. of "THE ELECTRICIAN" (950 pages), bound in strong cloth. Price 17s. 6d., post free 18s. 6d. Also ready, Cases for binding. Price 2s., by post 2s. 3d.

A complete set of "THE ELECTRICIAN" (1878-1900) can now be supplied. These sets are very scarce, and early application should be made.

AMERICAN ENGINEERING COMPETITION.

"An Englishman visiting the United States at the present time can hardly fail to be impressed by his own countrymen's want of knowledge of the growing manufacturing industries of America and the indifference displayed by British manufacturers towards the increased rivalry to which they may any day be subjected from across the Atlantic—a rivalry which will surely come as soon as the present excessive home demand in America slackens."

Thus recently commenced a series of articles in *The Times*, from the pen of a special correspondent who had spent much time in the United States in investigating the local conditions which have created a formidable and increasing competition with the home and foreign engineering industry of the United Kingdom. The attitude of British engineers and engineering manufacturers towards this competition is diversified. Some deny its existence to any large extent; others belittle its significance, while admitting that much American engineering plant is sold in this country; some regard it as the inevitable decline in the industry of Britain; others view it without alarm, and predict that the depression in British engineering enterprise will prove but transitory. It is important, when seriously approaching this question, to have regard to its three main aspects—viz., the fact of the competition, its significance, and its remedy as regards the retention and recovery of British industrial prestige. Intelligent electrical engineers—those who are watching, for example, the development of electric traction in this country—should need no more proof than their own observation affords, as to the fact of the alleged serious competition with British manufacturers. Should any reader require additional evidence we commend him to the series of articles in *The Times*. With regard to the significance of the competition, there probably is room for greater latitude of opinion with respect to its actual existence. Nevertheless, we think that there are strong indications that the American invasion of the British machinery market will make it more and more difficult for the home manufacturer to hold his ground. Attention, in this connection, should be paid to the pertinent remark which closes the above quotation from *The Times*. Should a time arrive when the American home demand in, say, electrical plant shall have perceptibly slackened, the huge momentum of their manufacturing business can hardly fail to be directed against British industry, even at lower

Digitized by Google

prices than at present. Doubtless a healthier reaction would follow, and British manufacturers, having lost heavily in the race, would put their shoulders to the wheel, and make up for lost time. But it would be far better to take time by the forelock, and see to it they never slackened nor lost an inch.

The remedy for the existing state of affairs, therefore, presses for consideration. We thoroughly endorse the remark of the writer in *The Times*, that "in spite of distance, and in spite of ancient prestige, we shall be beaten unless some of us wake up to the fact that obsolete appliances, old, slow methods, and the carelessness of customers needs must give place to something more businesslike and more intelligent." The remedy, in the first instance, is for the leaders of our engineering industry to travel and see what is being done abroad; next, for them to ascertain truly and without bias or prejudice the comparative merits of what they see; and lastly, for them to bring their methods and plant up to the standard of the best practice possible. It requires a belief in the possibility of foreign industrial superiority to induce them to travel; so, many of them stay at home. It requires courage and foresight to scrap costly existing plant and erect more costly and newer plant; so, many of them plod on in the old, old way of their forefathers. They bury their heads ostrich-like in the sand, and willingly are ignorant of the storm that must overwhelm them. Fortunately, not all of our British leaders of engineering industry are thus foolishly-minded. There are some who are willing to recognise what in American methods is superior to our own. These, too, instead of regarding this superiority as an evidence of British degeneration, are actively endeavouring to assimilate these improvements to British soil and circumstance. An excellent example of this is afforded in the organisation of the English Electric Manufacturing Co., whose works at Preston have been started during the past week. Here British capital and, largely, British labour have been combined with American technical skill and organising ability to produce a group of workshops which strike the keynote of the newer electrical manufacturing engineering in this country. Our readers will find an illustrated and detailed description of these works in our present issue; and we venture to think that the impression they will derive from its perusal will not greatly differ from that of the large gathering of visitors at the works last week, namely, that the harmonious blend of American skill and experience with British financial enterprise on British soil is a real and effective solution of the problem of American engineering competition.

MUNICIPAL ELECTRICAL ASSOCIATION.

Wednesday, June 20th.

The fifth annual Convention of the Municipal Electrical Association was inaugurated on Wednesday last at the Technical College, Huddersfield, under the presidency of Mr. A. B. Mountain, the Corporation electrical engineer at that town. There was a large and representative assembly of municipal electrical engineers and chairmen of electricity committees, besides a good sprinkling of visitors. The proceedings commenced at 10 a.m. with an address of welcome by the Mayor of Huddersfield, Mr. Alderman Helliwell, after which the Associates' prize was presented to Messrs. J. R. P. Lunn and P. S. Thompson. Mr. A. B. Mountain then read his presidential address, which we reprint on another page and comment on in our editorial columns.

The business for the morning included two Papers on "Means for Stimulating the Demand for Electrical Energy," by Ald. W. Potter, of Taunton, and Mr. H. C. Bishop, of Wigan. At the close of a long debate on these Papers a brief hour was devoted to the reading and discussion on two Papers on "Electricity Works for Small Towns," by Mr. C. S. Vesey Brown of Lincoln, and Mr. G. M. Harris of Bray. The debate on the first batch of Papers was opened by Mr Faraday Proctor, of Bristol, who criticised several of the popular means for stimulating demand. He considered that the usual system of so-called free-wiring is on a wrong basis, as it tends to discourage the long-hour consumer. Public lighting charges, he considered, ought to be divided into two distinct items—the charge for the energy consumed, and the charge for maintenance. Only in this way could a fair comparison be made with other charges. Messrs. Wilmshurst, Nisbett, Newington, Edgcome and Chamen, besides several chairmen of committees, joined in the discussion, and expressed a great diversity of opinions on the questions of free-wiring and kindred matters affecting stimulation of supply. Mr. Newington denied that in Edinburgh they were in need of stimulants; and several other speakers testified to the difficulty in coping with the rapidly-growing demand for current. We shall give a report on this discussion in our next issue. The remaining two Papers were taken less seriously, partly owing to lack of time. We hope to publish a full report of the joint discussion on these two Papers in an early issue.

In the afternoon, after luncheon in the Town Hall, the Association divided into a number of parties and paid visits to electrical and other works in the neighbourhood and at Bradford. In the evening the Association was entertained at dinner by Mr. Joseph Hopkinson in the Town Hall.

(*To be concluded.*)

FREE WIRING.

BY E. E. HOADLEY.
(City Electrical Engineer, Worcester.)

In a great many places in England there are stations that have been in operation for five or six years, and are now getting into that condition in which their maximum load or their lamp connection does not increase so quickly as it did in the first two or three years of their existence; in other words, the chief public buildings, business premises, hotels and those private houses whose occupiers can well afford to pay for their installations are already taking a supply, and some inducement is necessary in order to get the smaller shopkeeper and occupiers of the smaller houses to use electricity. The chief obstacle to its use by this class of people is undoubtedly the large amount of money which must be spent to cover the first cost of wiring and fitting up their premises, premises of which, in many cases, they are only quarterly tenants.

That it was desirable to assist this class of consumer was recognised some years ago, and for this purpose (among others) the National Free Wiring Co. was formed. This company has started operations in a great many towns in this country, and by its efforts a very large number of consumers have been connected to the mains by the various companies and municipalities; consumers who in all probability would not otherwise have become users of electricity. Here in Worcester the Free Wiring Company started in 1898, but owing to various causes has not met with as much success as elsewhere; in 1898 only 18 consumers were obtained by the company, in 1899, 17; and this year down to the present date, when the company's connection with Worcester ceased, nine.

These results can only be looked upon as disappointing; investigation and inquiry from consumers have elicited the following as the probable causes. The business was worked in conjunction with another town in which the supply was just being started, and where customers were plentiful; for this reason business in Worcester did not receive that amount of "push" which was necessary if many consumers were to be obtained. Consumers complain that the clauses in the agreement relating to purchase of the installation are unnecessarily harsh, and that the extra charge of 1d. per unit on all electricity consumed is practically an addition of 25 per cent. to their electricity bills, and in the case of publicans is even more, being very nearly 30 per cent.

Last autumn the Free Wiring Company gave the Corporation notice that, in order to make things pay in Worcester

Digitized by Google

they would be unable to wire bedrooms, &c., on the free wiring system, and could only wire them if they were paid cash for such lights, and asked to be allowed to amend their agreement to that effect. To this the Corporation would not agree, as the larger proportion of the free-wired consumers were drawn from the occupiers of private houses, and the system would not be of much benefit to these unless a man could have his bedrooms wired. To this action of the Corporation the Free Wiring Company replied by giving the necessary six months' notice to terminate their agreement.

At this stage, as I was convinced of the benefit of helping a consumer to wire his premises, I induced my committee to go in for a scheme of free wiring for themselves. A scheme was prepared by the town clerk and myself, approved by the Council, and, as considerable doubt was expressed as to whether the Local Government Board would grant a loan for such a purpose, a letter was written to the Local Government Board asking if they would entertain an application for a loan for free wiring. The Board replied that they were prepared to consider such an application, but if they did grant a loan it would have to be repaid in ten years. After this reply, application is now being made for a loan of £1,000 for free wiring purposes in the City of Worcester.

In the scheme set out below, the chief points that were kept in view were: (1) To make it as cheap and attractive as possible to the consumer; (2) To allow the consumer to pay for the installation in almost any way that suited him best; (3) Not to interfere in any way with the trade of the local contractors, but to further the putting in of good work and well-designed accessories; (4) In cases where the consumer only hires the installation, to charge him a rent calculated at a certain sum per lamp installed, and not to add a certain sum to his electricity bill for every unit of electricity consumed. That there is a good deal to be said for and against each method I am well aware, but an experience of both methods has led me to believe that the charge per lamp installed is the better way. The chief objection to this is that it is possible that a tradesman may only instal lamps in his window or shop where he uses them but a very little time per day, and may not instal them in dark passages, &c., where he will use them many hours per day. This objection, however, will in some measure be overcome, as each installation will be planned, &c., by an official of the Corporation electricity department, who will advise the consumer how to use his lamps to the best advantage. By the other method the best customers of the Electricity Works are penalised most, and many people who would be profitable consumers from the works' point of view, *i.e.*, would use a large number of units per lamp installed, are deterred from having their premises wired.

Below are copies of the circular that will be sent to probable customers and of the agreement they will be required to enter into:—

CITY OF WORCESTER.

WIRING PRIVATE HOUSES, &c.

The City Council being desirous of extending the use of electric light, and especially of enabling those citizens who do not live in their own houses to enjoy the advantages derivable from its use, has decided to undertake the wiring of private houses, &c., and the installation of the electric light therein. The Council does not propose to carry out the work by means of its own staff in the electricity department, but to entrust it to some of the local wiring contractors, who can be safely trusted to give satisfaction. The mode of proceeding, and the terms on which the Council will undertake the work, will be somewhat as follow:—

Any citizen desiring an installation of electric light in his house, shop, &c., can obtain from the electricity department a form of application. This must be filled up, signed, and forwarded to the electrical engineer. The premises will then be inspected, and the applicant's views ascertained; and the electrical engineer will prepare a specification of the work and an estimate of its cost. For this service the applicant will be charged a fee at the rate of 10s. for the first £5 or part thereof; 10s. for the second £5 or part thereof; and 10s. for every subsequent £10 or part of £10 of the engineer's estimate.

It may here be mentioned that the Council's installation will only include plain fittings, but the applicant can substitute any more expensive fittings he likes at his own expense; or, by special arrangement, the extra cost can be liquidated by a small increase in the instalments of purchase money or rent, as the case may be.

The specification having been prepared, the Council will proceed to obtain tenders from local wiring contractors to carry out the work. The tenders will be submitted for the applicant's consideration. He may, at this stage, abandon the proposal to instal the light if the lowest tender is much in excess of the electrical engineer's estimate. Assuming, however, that the applicant decides to proceed, the Council will accept one of the tenders, and the applicant must decide whether he will purchase or rent the installation. To enable the applicant to decide, the following terms for a purchase or a rental have been approved by the Council.

1. *Purchasing the Installation.*—The purchase may be on either of the following methods: (*a*) By one payment in cash, including the sum to be certified by the electrical engineer as payable to the wiring contractor, and the Council's fee for the specification. This method avoids all complications and needs no consent on the part of the owner of the property if the applicant is only a tenant. (*b*) By deferred payments. The applicant will be required to pay down one-tenth of the cost of the installation, *i.e.*, the amount certified to be due to the wiring contractor and the Council's fee for the specification, as soon as the electrical engineer gives his certificate of completion of the installation, and the balance can, at the applicant's option, be spread over three, five or seven years, and be paid by 12, 20 or 28 quarterly instalments, including interest at 4 per cent. on the amount for the time being remaining unpaid.

It need hardly be explained that until payment of all the instalments the installation will remain the Council's property, and that the consent of the owner of the premises is essential to this arrangement. A statement is appended (see Schedule A on page 327) showing what an applicant would pay on this method for an installation costing £20 where the payments are spread over five years.

2. *Renting the Installation.*—Under this method, the applicant must pay to the Council the annual sum of 1s. 3d. for every lamp installed in his premises, but where two or more lamps are fitted to one point the annual charge for one will be 1s. 3d. and for each of the others 6d. per year. The applicant must in addition, of course, pay the charge for the electricity he consumes; and the installation will remain the property of the Council. If the applicant prefers to instal expensive fittings at his own expense, the Council will allow the sums mentioned in the list set out in Schedule B. The consent of the owner is essential to this arrangement also. An applicant who commences to pay for an installation on the rental basis will be permitted to purchase the installation at the end of any year, on terms to be specially arranged.

Whether the applicant decides to pay for the installation by deferred payments, or to rent it, the following conditions will apply:—

(1) The Corporation will guarantee the efficient working of the installation (except in case of accident, wilful damage, or the occurrence of fire, storm, or tempest) for 12 months from the electrical engineer's certificate of its due completion; but the Council is not to be liable to replace any worn-out or defective lamps.

(2) The owner of the property must be a party to the arrangement, and sign the Council's form of agreement.

(3) The Council will render to the applicant quarterly a statement of the amount due from him up to the preceding quarter day.

(4) The applicant must sign the Council's form of agreement providing for the observance of the terms herein mentioned, and such other terms as the Council has found necessary.

N.B.—Forms of the agreements referred to can be obtained at the Electrical Engineer's Office, Guildhall, Worcester. The electrical engineer will superintend the execution of the work by the contractor whose tender is accepted, but the Council makes no charge for this supervision..

AGREEMENT.

AN AGREEMENT made the ..... day of ..... 19..... between .....of ..... Worcester (herinafter called "the Consumer"), of the first part ..... of ..... (hereinafter called "the Landlord") of the second part, and THE MAYOR, ALDERMEN, AND CITIZENS OF THE CITY OF WORCESTER (hereinafter called "the Corporation") by ..... their electrical engineer of the third part, WHEREAS the landlord is owner of the house known as ..... situate at ..... Worcester, and the consumer is the tenant thereof, AND WHEREAS the consumer and the landlord are desirous of having the said house installed with the electric light, and have applied to the Corporation to wire the said house, which they have agreed to do, subject to the following terms and conditions. NOW IT IS HEREBY MUTUALLY AGREED as follows:—

The Corporation will wire the said house for electric light, with fittings and the first set of lamps complete, for.....lights in accordance with the terms of the specification deposited at the electricity department of the Corporation. The consumer need not take the fittings allowed him by the specification, but he may, if he prefers it, provide his own, subject to their being passed by the electrical engineer for the time being of the Corporation (hereinafter called the electrical engineer), before they are used in the installation; and in that case the Corporation will make the consumer allowances according to the prices specified in the schedule to this agreement, to be deducted from the consumer's payments hereunder. The cost of the installation shall be such sum as the electrical engineer shall certify to have been the cost thereof, and shall include the electrical engineer's fee for preparing the specification, and supervising the execution of the work. Such cost is hereinafter referred to as "the cost of the installation." All the fittings except such, if any, as are provided as aforesaid by the consumer, shall remain the property of the Corporation.

The consumer will pay to the Corporation so long as he occupies the said house the sum of 1s. 3d. per annum for each of the said lights, and a similar sum for each further light which may hereafter be installed in the said house; but where two or more lights are fitted to one point the annual payment for each light after the first shall be 6d. Such payments shall be made quarterly—on January 1st, April 1st, July 1st, and October 1st in every year—the first payment or a proportion thereof to be made on the first of the said days which follows the completion of the original installation. The consumer will, in addition, pay the Corporation's charge for electric current, and will abide by the conditions upon which the Corporation now supply, or may hereafter supply current to ordinary consumers. The

Digitized by Google

consumer will also observe and abide by any rules and regulations made by the Board of Trade or other competent authority, and the passing by Parliament of any Act inconsistent with this agreement or any part thereof shall not, unless expressly so provided, invalidate this agreement, but the same shall continue in force so far as its provisions remain unaffected, unless the Corporation consent in writing to its termination.

The consumer will keep and maintain all the fittings in the said house, whether provided by the Corporation or the consumer, and the whole installation, in good order and condition. The consumer will, on ceasing his occupation of the said house, leave the installation in good order and condition, and hand over to the Corporation all their fittings in the said house, complete and in good repair and condition as aforesaid.

The Corporation shall have power, on giving 24 hours' notice, and at reasonable times, by the electrical engineer or other properly authorised official, and with or without workmen or others, to enter the said house to view the state of repair and condition of the fittings whether provided by the Corporation or the consumer, and of the installation; and of all defects and wants of reparation then and there found in such fittings or installation, to give or leave on the premises notice in writing to the consumer, and he will within the space of three weeks after such notice or sooner if required, repair and make good the same. If the consumer shall make default in repairing and making good any of the said defects of which notice in writing has been given as aforesaid, the Corporation may enter on the said house and repair the same at the consumer's expense, and the expenses of such repairs as certified by the electrical engineer, whose certificate shall be final, shall be paid by the consumer to the Corporation and shall be a debt due from him to them.

The landlord or the consumer may purchase the installation on either of the following terms:—

(*a*) By paying to the Corporation the cost of the installation in cash; or

(*b*) By paying to the Corporation in cash one equal tenth part of the cost of the installation, and the balance of such cost by equal quarterly instalments extending over ..... years from the date of the first payment, and with each instalment interest at 4 per cent. per annum on the amount for the time being remaining unpaid.

Whichever method of purchase is adopted the annual payment of 1s. 3d. per light or 6d. per light, as the case may be, must be paid up to the date on which the whole cost of the installation, or the first instalment thereof, as the case may be, is actually paid to the Corporation. Upon payment to the Corporation of the whole cost of the installation, with interest where payable, and all charges for electric current supplied to the house, the installation shall become the property of the landlord or consumer who pays for the same.

In case the consumer elects to purchase the installation and after payment of one or more instalments of the purchase money, ceases to occupy the house, he shall be liable to pay a proportion of the current quarterly instalment, with interest, up to the date of his so ceasing to occupy; but he may, with the landlord's consent, obtain and deliver to the Corporation a duly stamped agreement, signed by the person to whom the landlord may let the said house in immediate succession to the consumer, agreeing in such manner as the Corporation require, to carry out the consumer's obligations under this agreement; and in such event, the said incoming tenant shall be entitled to the advantages and be subject to the liabilities of the consumer under this agreement. While either landlord or consumer is purchasing the installation, all the clauses of this agreement shall continue in operation, but the due and punctual payment of the instalments of purchase money shall be deemed to be instead of the payment of the said yearly payment of 1s. 3d. per light, or 6d. per light, as the case may be.

Any notice, demand, or other writing to be served under this agreement shall be deemed to be duly served on the consumer when the same has been left at his usual or last known place of abode, and on the Corporation when the same has been left at the office of the electrical engineer. In case any of the conditions herein contained shall not be observed by the consumer, or a receiving order shall be made in respect of the estate of the consumer, or the consumer shall compound with his creditors or execute an assignment of his effects for the benefit of his creditors, or the consumer shall commit or suffer any act of, or take any proceeding having effects or results similar to bankruptcy; or the said wires or fittings of the Corporation, or any portion thereof, shall be seized or taken in execution (or shall be attempted so to be) under any process of any Court, then and in any of such cases the whole cost of the installation, where the consumer is paying an annual sum per light, and in every other case the whole of the balance of such cost, after deducting any instalments of the purchase money which have been paid, shall immediately become due and payable to the Corporation.

In case any payment to be made to the Corporation under this agreement is more than 14 days in arrear, the Corporation may, if they please, and without losing their right to sue for the said unpaid payment, enter the said house and remove the installation and all their fittings, and any damage unavoidably caused thereby to the said house, which the Corporation are hereby bound to pay to the landlord, may be also recovered by them from the consumer. In case the occupier of the house for the time being is not a consumer of electricity supplied by the Corporation, the Corporation may, if they please, enter the said house and remove the installation and all their fittings, making good any damage unavoidably caused thereby to the said house.

The landlord agrees to such of the above provisions as affect his rights, and he also agrees not to disturb the said installation without the leave of the Corporation in writing, which shall not be unreasonably withheld, or to distrain upon the said fittings, and further that he will permit their removal by the Corporation at any time subject to the terms of this agreement, the Corporation making good any damage caused thereby to the said house. Nothing in this agreement shall in any way affect the powers, rights, or remedies of the Corporation as the local authority under the Electric Lighting Acts, 1882 and 1888, or any order or regulations made thereunder, with respect to the said wires and fittings, but the said powers, rights, and remedies shall be and remain exercisable by the Corporation in every respect as if this agreement had not been entered into.

A FRICTIONLESS MOTOR METER.*

BY S. EVERSHED.

(*Continued from page 285.*)

Description of Frictionless Meter.—The essential working parts of the author's meter are shown in Fig. 7. The armature A, brake dish F, and train-driving coils D_1 D_2, are mounted on a mild steel axle *a*. The axle has a hard steel point at its lower end, resting in a jewel cup, J; its upper end has no mechanical support, but is main-

tained in position by the magnetic attraction of an iron rod, R, which is magnetised by the brake magnets M M through an iron yoke, Y, and forms the supporting pole. The distance between R and the end of the axle is adjusted by screwing R in the yoke Y until the vertical force nearly suffices to lift the whole weight of the arma-

ture, brake, and other parts attached to the axle. The arrangement is more clearly seen in Fig. 8, which is a section through the magnetic pivot. A magnetic pivot of this type may easily be made to support a weight of from 100 to 200 grammes.

* Paper read before the Institution of Electrical Engineers, May 10.

The commutator K is placed beneath the armature, and the wheel brushes *b b* are pivotted in frames attached to an ebonite plate E. The commutator and brushes are shown on an enlarged scale in Fig. 9. The segments are fine iridio-platinum wires supported at one end in an ivory collet and entirely free at the other end, where they impinge and roll on the brush wheels. The commutator is about 3mm. in diameter at the rolling circle; the wheels are about 36mm. diameter, so that they make one revolution to twelve revolutions of the commutator.

The pressure current is led to the brush wheels through their frames, and to ensure good contact between frame and wheel the step bearing of each wheel is an iridio-platinum pivot resting on a flat plate of the same metal.

A drum-winding is used for the armature, a break being made, in the ordinary course of winding, in each parallel, in order to insert the two little coils D_1 D_2. Thus D_1 is in series with one of the two parallels of the drum-winding, and D_2 in series with the other; they are consequently each traversed by one half of the whole armature

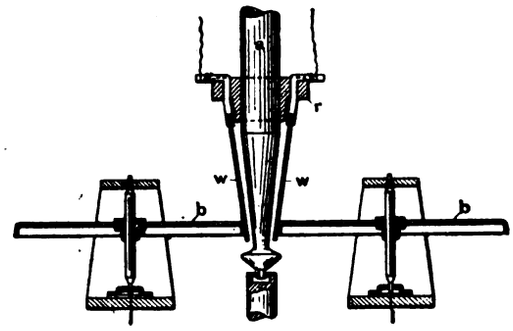

FIG. 9.—Elastic Commutator.

current, and since they are, electrically, a part of the armature-circuit, the current in them is reversed twice in each revolution of the axle. D_1 and D_2 are inserted at corresponding points of the drum-winding, so that their currents reverse at the same instant, and they are coupled up so that the two currents flow in the same direction and to all intents and purposes D_1 and D_2 behave like one coil.

Fig. 10 shows the connections of the train-driving coils in diagrammatic form, a Gramme winding being substituted for the drum for the sake of clearness. Surrounding the train coils D_1 and D_2, but not touching them, is a ring of soft iron P (Fig. 7), forming part of an iron lever L, mounted on an horizontal axle *p*. L is magnetised by induction from one of the brake magnets, an iron bar G serving to complete the magnetic circuit between S and *n*. The induction leaves the ring pole P, and passes radially through the train coils into the axle, and P consequently experiences a vertical

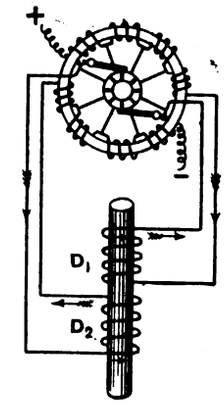

FIG. 10.—Diagram of Connections between Armature and Train Coils.

force alternately upwards and downwards as the currents in the train coils periodically reverse. The result is that L oscillates on its axis, making a double stroke or complete cycle once in every revolution of the armature. The motion of the lever is limited by stops, and is communicated by means of a pawl to a ratchet wheel, W, which is attached to the first axle of the counting-train T.

It will be seen at once that this device opposes no retarding moment on the armature axle. The only mechanical force called into play is in a vertical direction, and has no component tending to turn the axle. The train coils and magnetised lever form a reciprocating electric motor, and, during the time the ring pole is moving up (or down) there is a back E.M.F. in the train coils, and the product of this back E.M.F. into the armature current and the time gives the consumption of electrical energy per stroke. It is, of course, equal to the mechanical work done—product of force on P

Digitized by Google

into length of stroke. The force actually provided is far greater than that necessary to drive the train. The friction of an ordinary train is just overcome by a turning moment of about 4 dyne cm. applied to the worm or pinion commonly used on a meter axle to gear into the first wheel of the train; 6 dyne cm. will generally keep a train running at a speed a good deal higher than anything save a short circuit can produce. The author has tested many trains taken out of different electric meters, and curiously enough they differ very little as regards friction.

Now, if the train were geared to the axle in the usual manner, and required a moment of 6 dyne cm. to keep it going, the work done by the meter in driving the train, being, of course, 2π times this moment in each revolution, would be about 38 ergs. The stroke of the train-driving lever is about 1·0 cm., so that the force upon it must be at least $\frac{38}{1·0} = 38$ dynes. The force actually obtained is about 750 dynes, which leaves an ample margin for accidental friction. It is assumed that the lever does no useful work on its return stroke.

A number of different forms of this train driver have been designed, and several of them have been tested in actual work. Fig. 11 shows a modification characterised by the same fundamental principle, namely, a coil producing an alternarely upward and downward force upon the free end of a lever. In this modification the two train coils D_1 and D_2 are coupled back to back, so that they produce a consequent pole in the space between them, and the movable coil attached to the end of the lever is alternately forced up and down. This coil forms part of the series resistance in the armature circuit, and carries the whole of the pressure current. Fig. 11 is intended for alternate current meters, where a permanently magnetised lever would, of course, be useless.

There are other features in the design of the meter which will be of interest to station engineers, but which are hardly of sufficient general interest to warrant such a detailed description as has been given of the means adopted to reduce friction. The whole of the working parts of the meter, with the exception of the main current

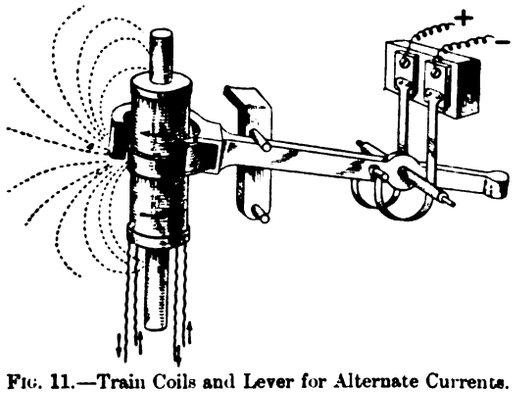

Fig. 11.—Train Coils and Lever for Alternate Currents.

coils, are attached to a light framework, which is bolted to the top of the casting which forms the back, top, and bottom of the meter case. The other three sides of the case are formed by a bent sheet of zinc, which is screwed and sealed to the casting. The terminals project below the bottom and are covered by an insulating box, which may be sealed after connecting up on the consumers' premises. The Foucault brake is in the form of a shallow dish, and the two brake magnets are fixed in positions which make it impossible for any excess of current in the main coils to demagnetise them. Their stray field is at right angles to that of the main coils.

Range of Frictionless Meter.—A meter in which frictional resistance is so small as 3 dyne cms. will obviously have an unusually long range, even if nothing be done to correct the small remaining friction error. If the same limits are imposed as were assumed in making up Table I.—namely, about 1 volt drop in the main coils and 3 watts wasted in the pressure circuit—the meter may be wound to give a maximum driving torque of 15,000 dyne cms. The friction is then only 0·02 per cent. of the full-load torque. The resulting range and uncorrected errors are set out in Table II.

It will be seen that the standard range of this uncorrected meter is 1 to 250. The range may be greatly extended by introducing a device to compensate for friction, and the very long range of such compensated meters may be useful in special cases. The author believes, however, that if advantage is taken of the enormous reduction in friction to improve the meter in other ways, even at a sacrifice of some part of the long range, a more generally serviceable instrument will be secured. An examination of the available statistics with regard to numbers of consumers and the lamps (or equivalent load) connected to the mains of the supply undertakings of this country shows that on an average about 50 8 c.p. lamps or their equivalent are wired per consumer. If we assume these to be 40-watt lamps, the maximum load of the average consumer will be

Table II.—*Errors of Uncorrected "Frictionless" Meter.*
Maximum Driving Torque = 100, Friction = 0·02. Full Speed = 100; Arbitrary Units.

Driving moment. M.	Friction *f*.	Speed (numerically equal to M − *f*).	Percentage error.
0·02	0·02	0	inf.
0·04	0·02	0·02	− 50

0·40	0·02	0·38	− 5
1·00	0·02	0·98	− 2
10·00	0·02	9·98	− 0·02
50·00	0·02	49·98	− 0·04
100·00	0·02	99·98	− 0·02

Standard range = 1 to 250.

about 2,000 watts and his minimum about 40 watts. Now, although the maximum demand of the consumer will not much exceed half this amount (the "maximum demand" for nine of the largest undertakings in London is 46 per cent. of the total load connected), the meter installed may be assumed to be wound for 2,000 watts, so that, if the meter is to register correctly at the smallest load, its range must at least be 1 to 50. It is, of course, quite probable that within a few years consumers will be using lamps taking far less power, but there is no reason to believe that the ratio of smallest load to maximum load will be much, if at all, affected by the introduction of more economical lamps. The standard range may then be reduced to 1 to 50, but any further decrease will be at the expense of revenue.

A reduction of range enables us largely to reduce the power wasted in the armature circuit, but a limit to this reduction is imposed by the fineness of the wire it is possible to employ upon the armature and in the series resistance. On this account it is at present not advisable to reduce the pressure current below 0·01 amperes, and this value has therefore been adopted for all voltages. The waste of power in the armature circuit is then one watt for 100 volts, two watts for 200 volts, and so on. The voltage drop in the main coils may be left at one volt, this being only one-half per cent. on the 200-volt supply which is now being rapidly adopted. An additional improvement in accuracy has been secured by making the meter astatic, so that it is not affected by external magnetic forces.

Astatic Meter.—The astatic meter has its armature divided into two equal portions, placed one above the other, on the axle, as shown in Fig. 7. These two parts, although physically separated, form one complete drum-winding connected to a single commutator. Following the process of winding a drum, the first coil will be wound on the lower spider; the second will be wound on the upper spider in exactly the same position as regards azimuth as it would ordinarily occupy if wound on the lower armature, but it is wound in the opposite sense. The third coil is on the lower spider; the fourth on the upper and reversed in sense. Thus numbering the coils in succession, all the odd numbers will be found on the lower half armature and all the even numbers will be found on the upper half. Each half armature is surrounded by its own pair of main-current coils, the two pairs being coupled so that the current flows in them in opposite senses, their magnetic fields being in opposite directions. This reversed coupling is, of course, necessary to drive both parts of the armature the same way, but it has the incidental advantage that it greatly reduces the stray field of the main coils, and so renders the brake magnets doubly secure against excessive currents.

The advantage of an astatic armature is, however, only gained at the cost of a reduction in driving torque, for a little consideration will show that when a non-astatic drum armature is converted to the astatic form shown in Fig. 7, and one-half of the copper on the main coils is taken off and made up into a second pair of coils, so that each of the two parts of the armatures may be driven, the field in which the armature rotates is halved although the number of turns on the armature itself remains the same as before. Probably very few consumers possess the requisite combination of knowledge and knavery to enable them to attempt a reduction of their electric light bill by the use of a strong magnet placed near the meter, but meters are always liable to be fixed in positions where stray fields exist, and the author is inclined to believe that the astatic armature will prove to be a clear gain.

To sum up—the astatic meter is wound to give a driving torque of about 2,000 dyne cm. at full load; the current in the armature circuit being 10 milliamperes and the drop in the main coils 1 volt. The frictional resistance is about 2 dyne cm. when the meter is new, and the tests to be presently referred to show that a frictionless meter will run for many million revolutions before any serious increase in friction takes place.

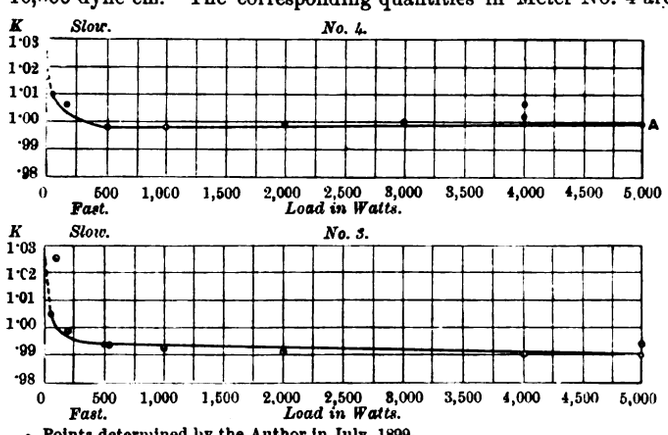
Compensation for Remaining Friction.—The initial value of friction is compensated for by means of a little strip of sheet iron placed within the field of the main coils. When once magnetised by the main current the coercive force of the iron is sufficient to provide the very small driving moment required to overcome friction. As has already been pointed out, compensation for friction will cause a meter

Digitized by Google

to run at no load if it is subjected to vibration ; but when friction is only a very minute fraction of the maximum driving torque, the over-registration of a corrected meter would be quite negligible even if it could occur, but, as a matter of fact, the elastic commutator has a directing moment upon the axle which prevents the meter from running until the driving torque is two or three times as great as the moment of friction. Hence it is impossible for the compensator to start the meter or to keep it running. The corrected meter starts with from $\frac{1}{500}$th to $\frac{1}{300}$th of full load, and has a standard range of about 1 to 200.

The range and accuracy of a corrected meter are well exemplified by the two curves given in Fig. 12, which show the variation in the constants of two meters having a ratio of about 1 to 1,250 between friction and full-load torque. This happens to be approximately the same ratio as that it is proposed to adopt as a reasonable compromise between the conflicting elements of accuracy and waste of power, so that although these meters have a much larger frictional resistance than is now obtained, yet as regards accuracy and range they are very nearly identical with the astatic meter. The latter has much less driving torque, but its frictional resistance is smaller by a corresponding amount.

The larger friction in meters Nos. 3 and 4 arises from the fact that they were made before the adoption of the elastic commutator and other improvements They are fitted with very small commutators with rigid sections made of iridio-platinum wires, which form a sort of squirrel-cage round the axle. The diameter of the commutator is about $\frac{1}{16}$in. Fine wire brushes are used, pressing very lightly upon the commutator. The frictional resistance in Meter No 3 is 7·9 dyne cm , and the driving torque at full load is 10,000 dyne cm. The corresponding quantities in Meter No. 4 are



• Points determined by the Author in July, 1899.
⊙ Points determined by Mr. Rennie at the Board of Trade Laboratory, September, 1899. At *A*, Mr. Rennie's observation falls exactly on a point determined by the Author.

FIG. 12.--Curves for Meters Nos. 3 and 4 showing Variations of Constant with Load.

approximately the same, but they were not accurately measured. These meters are corrected by a thin steel rod having the necessary coercive force, and, as will be seen on reference to the curves they are both slightly under-corrected. The Board of Trade limits are, however, nowhere exceeded throughout the whole range from 0 to 5,000 watts.*

(To be concluded).

MEANS OF STIMULATING THE DEMAND FOR AN ELECTRICITY SUPPLY.†

I.—BY ALDERMAN POTTER, J.P.
(Chairman of Electrical Committte, Taunton.)

What are the hindrances and difficulties in the way of an extension of electricity supply? And by what means may they be overcome so as to sweep away any lingering prejudices, and to create within the public mind a preference for electricity over every other kind of illuminant? These are questions not only of great interest to all who are in any manner concerned in its financial success, but which have been from time to time answered in various ways, with more or less beneficial results. In acceding to the request of the Council to write a Paper on this subject, I wish it to be clearly understood that I disclaim all idea of being able to bring forward any new or original suggestion, but having seen the results attending some of the suggestions which have from time to time been made, I am hopeful that my experience may be of some use, especially to those who are connected with small electrical undertakings in poor districts which have not attained a profit-making stage.

In the earlier stages of electric lighting one of the most serious hindrances to its extension was its extremely erratic character and unreliability, *e.g.*, it so frequently went out at most inconvenient times, causing such confusion and annoyance, that many persons otherwise favourably disposed would have nothing to do with it; but this uncertainty has become a thing of the past. The improvements that have taken place in electrical machinery, and the increased efficiency of electricians generally, are so great that where a generating station is equipped with modern plant, worked by a competent staff, anything beyond a very occasional, partial, or temporary failure is unknown, and its intermittent character no longer operates on the public mind as a hindrance to its growing demand. At the present time the initial difficulty that has to be overcome in order to stimulate the demand for an electricity supply by securing additional customers is that relating to the cost of electricity as compared with gas or oil. The advantages claimed for the electric light over every other kind of artificial illuminant, such as being more conducive to health, its cleanliness, convenience, and the saving effected through its use in painters and paperhangers' bills may not be denied, but they will fail in accomplishing the desired end unless it can also be shown that these advantages can be obtained with little or no additional increase in the light bill. Persons who have become accustomed to the use of electricity learn to appreciate its undoubted advantages so highly as to be willing to pay more for it than they formerly did for gas or oil, but in the case of a new consumer the advantages often appear somewhat mythical or remote, whilst the *cost* is present and real. The only way of meeting this difficulty appears to be that of charging as low a price per unit as possible, *after providing for all necessary expenses.*

In most instances it is found necessary to receive some assistance from the rates for the first year or so of an undertaking; but the aim of those having the management of municipal works should be to do without such assistance as speedily as possible. The wisdom of doing what some corporations do, charging one price for private lighting and a much lower price for public lighting, supplementing it year by year by a contribution from the rates, is very questionable; better charge both public and private lighting with its fair share of costs, and make the undertaking self-supporting. There is but little for a municipal undertaking to accomplish beyond this; there is nothing really gained to the ratepayers by making large profits if the price charged is high. Its aim should be, especially in the earlier years of the undertaking, not so much to realise a profit, to be applied to a reduction of the rates, as to supply the light, both public and private, at the lowest possible price, after meeting all expenses and providing for all contingencies. By so doing not only are the ratepayers directly benefited, but it is a means of stimulating the demand for an electricity supply, as also does the giving of rebate, after the current has been used a specified time, if care be taken to fix the time limit so as to include all who use the light for any reasonable time within its sweep The public do not understand the impracticability of taking a graduated discount off an electricity account, as is done off water or gas; therefore, when a consumer, who having a large number of lamps installed, but uses them only a short time, finds that he gets no rebate, though the amount of his bill be larger than that of his neighbour, who with fewer lamps installed, yet using them a greater number of hours, gets a rebate, he is dissatisfied and feels aggrieved.

At Taunton, the system first adopted was that of giving a discount according to the amount of the consumer's bill, but finding that that was a wrong principle to go upon, the demand indicator system was adopted, charging 6d. per unit for the first two hours' demand, and 3½d. after; the result being that few of the principal shopkeepers, living away from their business premises, exceeded the two hours' average, and therefore got no rebate; this gave rise to a great deal of dissatisfaction, and many threatened to give up the light. Some 18 months ago, the Electrical committee saw their way to reduce this time limit from two hours to one, with this result, that nearly all charged under this system get a rebate; all grievance is removed, and there has been a large increase in the number of lamps installed, not only through an increase in the number of consumers, but also by reason of the extension of the light in premises in which only a few lamps had been previously installed.

Another difficulty is connected with the cost of installation, especially in premises which are held for a short tenancy only, and in which gas is already laid on. Though the cost of installation has been very much reduced within the last few years, still many find themselves unable to bear the expense, and others are, not without reason reluctant to do so when they are only tenants of the premises they occupy. But this difficulty is effectually met by adopting the system of free wiring, which is also often the means of securing a most desirable class of consumers, small shop-keepers and householders, whose means are such that they could not afford the expense of having their premises wired. The National Electric Wiring Co.

* Meters Nos. 3 and 4 are in use in the meter-testing department of the Manchester Corporation as standards for checking the accuracy of other meters intended for commercial purposes, and the author is indebted to Mr. Wordingham for his permission to make use of the curves which accompanied the Board of Trade certificate. He desires also to thank Mr. Rennie, who very kindly supplied a copy of the tests made at the Board of Trade Laboratory.

† Papers read before the Municipal Electrical Association, at Huddersfield, June 20.

have gone in extensively for this. Although they do a large amount of contracting work, the backbone of their business is free wiring, and in this direction have been of immense service to many a struggling electrical undertaking, as under the terms of their agreement any person can have their premises wired and fitted up for the supply of electricity without any initial charge whatever, the Corporation or supply authority agreeing to pay to the Wiring Company so much (generally one penny per unit) on all electricity supplied through their wires and fittings. In some cases this penny is added to the price charged per unit, and is paid by the consumer, but this, which is perfectly fair and reasonable, is open to the objection that such consumers are apt to imagine that they have a grievance—that they are unfairly treated in having to pay more per unit than other persons. It is better to have one uniform price and charge all alike per unit; but to explain to those who apply to have their premises free wired that no rebate will be allowed them whatever their consumption, and that the rebate they would have received if the installation had been made at their cost goes to pay the company. This cannot be regarded other than fair by all concerned. Taking Taunton as an example, it is fair to the Corporation because the amount received from all our consumers is 5d. per unit. This is the average amount we receive under the rebate system, and also the nett amount we receive from those whose premises have been free wired. It is fair also to those who have installed the light at their own cost, as in the amount of the rebate they have some return for the capital expended. It does not press unfairly on those whose premises have been free wired, because if they find that their consumption is such that the rebate would be a good return on the cost of the installation, they can, if desirous of so doing, buy the company out by the payment of the cost price of the installation, plus 20 per cent., less 1½ per cent. per annum depreciation. If further proof be necessary to show the valuable help the Free Wiring Company is in stimulating the demand for an electricity supply, it will surely be seen in the following statement, showing the number of lamps installed by the company up to the end of 1899, under contract and free wiring:—

Lincoln	4,233	8 c.p. equiv.
Prescot	2,505	ditto
Worcester	1,745	ditto
Blackpool	6,410	ditto
Taunton	4,903	ditto
Shoreditch	3,236	ditto
South London Supply Corporation	3,319	ditto
Wallasey	11,910	ditto
Crystal Palace Electric Supply Co. (Ltd.) (since July, 1899) over	3,000	ditto

In Lincoln not a single application for current had been received by the Corporation before the company entered into a contract. They were, however, able by the time the plant was ready to provide such a number of lights as to render it necessary for the Council to take steps to increase the plant. At Taunton, during the first year of the contract, upwards of 3,000 lights had been installed. In Wallasey, at the end of 1898, over 70 per cent. of the consumers connected with the supply had been obtained by the company, and they were taking over 80 per cent. of the output. As, however, the company require to be paid the minimum sum of 1s. for every 8 c.p. lamp, care must be taken to see that their agents do not instal lamps of greater candle-power than is actually required.

Closely allied to the question of free wiring is that of prepayment, or slot meters, which finds favour with consumers in poor and weekly wage-earning districts, many of whom would find it a difficult matter to pay a quarterly account, but prefer to pay as they go. Further, by the use of slot meters there is no dispute about the amount of the bill, nor any bad debts. Often the supply creates the demand. This is so in connection with electric lighting; the demand is stimulated by the supply undertakers adopting a bold spirited policy in laying mains in likely districts, even though they do not succeed in getting such a number of promises to use the light as, in the opinion of the over-cautious, would justify the expenditure. It is frequently the case that persons who, when canvassed for this purpose, object to give a definite promise, are amongst the first to become consumers when the mains are laid, and it is only a question of joining them up. Some three years or so ago the Taunton Corporation were asked to lay mains in order to light up two private residences in opposite directions, one a mile and the other nearly two miles from the generating station, the owners agreeing to pay 5 per cent. on the outlay until such time as the revenue from these mains should reach a certain amount. Notwithstanding this agreement there was opposition to carry the mains so far, it was said, for one house, but the mains were laid, and the results have fully justified such a course, for with the exception of the principal business portions of the borough these two lengths of mains are the most remunerative. The application of electricity for power and heating purposes presents many opportunities for stimulating the demand, and in stations having a day load for lighting purposes such an addition is very profitable.

In conclusion, it may be stated that Taunton is not a large rich manufacturing town, but a small agricultural town, at a great distance from the coal fields. There are no large consumers connected with its mains, such as theatres, large hotels, and public rooms, but principally short-hour shopkeepers and middle-class residences; but working more or less on the lines indicated in this Paper. The loss of over £900 a year on the revenue account up to 1893 (when taken over by the Corporation) has been converted into a profit of over £2,000 a year, with every prospect of an increased and continued success.

II.—By H. Collings Bishop.

(Borough Electrical and Tramways Engineer, Wigan.)

The subject of this Paper is one which has, I think, received far too little attention from most central station engineers—the chief engineer of a central station cannot be fully conversant with the best means of inducing people to use electricity, unless he is also the leading spirit in the accountant's department. He should have at his finger ends the whole of the business side of the station as much as the engineering side, as without this he will have a difficulty in accomplishing his purpose, viz., to obtain a high load factor and an increased demand for current. To stimulate the demand for electricity means to increase the sales and to lower the costs, and there are many ways of doing this. Some of these methods of course are already in use, among which are some that are not as satisfactory as at first sight they appear. The following are some of the means which seem to promise well: (1) Low price, (2) sliding scale, giving long-hour consumers a lower rate, (3) free use of meters, (4) free connection of services, (5) a free wiring system, (6) a system of wiring on the instalment plan, (7) a specially low rate for current used for motive power, heating, or manufacturing purposes, (8) the hiring out of motors, arc lamps, heating, and cooking apparatus (including inspection and repairs), (9) to enable short-hour consumers, with a large number of lamps connected, to obtain the current they require at a lower rate than the maximum, and to reduce at the same time the load demanded from the station. Each of the above methods may be considered acceptable to the consumer, and I now propose to consider what would be the probable effect of them on the output of the station, and to show how the consumer would be benefited by their adoption. The first four speak for themselves and require no explanation, so we may proceed to the fifth, viz.:—

Free Wiring.—It is difficult to understand why this system should be thus named, as there is very little that is free about it. It may be of great benefit to one consumer and of no use to another, as the charges are made on the number of units used, with a minimum payment of 10 per cent. on the cost of the installation, with trade profit added. The consumer who is most benefited by the use of "free wiring" is the one who uses the smallest number of units, and therefore does not have to pay more than the 10 per cent. minimum charge for the use of the wiring and fittings.

Instalment Plan.—This should be very popular with all classes of consumers, and I would suggest the following prices as both profitable to the wiring syndicate and acceptable to the consumer. The consumer should be allowed to have any kind or class of fitting that he prefers, the price of the installation to be ascertained in the following way: The prime cost of the work plus 15 per cent for standing charges, plus 20 per cent. for trade profit, plus 2½ per cent. for inspection by the "undertakers." The total amount to be paid as follows: 10 per cent. on the completion of the work and the balance in 16 quarterly payments, plus 5 per cent. per annum on the portions remaining unpaid, the installation becoming the property of the consumer on payment of the last instalment.

It may be of interest to see how these two systems compare with each other, and with a cash payment. We will suppose these three instances apply to the same building. Current is assumed to be supplied at the following rates:—7d. per unit for the first hour's daily average use, and 2d. per unit for all used beyond that time.

Cash.—A. instals in his shop 15 lights, the cost works out as follows:

Prime cost	£11	5	0	
Standing charges	1	13	9	
Trade profit	2	5	0	
				£15 3 9

During a four years' use of the light the consumer will have paid the following amounts, including interest on his outlay: No. of units used 3,800, and the average demand 4 amperes at 230 volts.

Current at 7d. per unit	£39	3	5	
Current at 2d. per unit	20	9	6	
Interest on capital at 5 per cent.	3	0	8	
Renewal of lamps	2	0	0	
Depreciation 2½ per cent. per annum	1	10	4	
Capital cost of fitting up premises	15	3	9	
				£81 7 8

Free Wiring.—I have taken the charges to be as follows: ¾d. per unit extra for all current used at the 7d. rate, and ½d. per unit for all current used at the 2d. rate, with a minimum charge of 10 per cent. per annum on the capital cost, the consumer having the option of purchasing the installation at the end of four years on paying the

Digitized by Google

capital outlay *less* 10 per cent. for depreciation. Taking the same case as in the last instance the cost will be as follows :—

Current at 7d. per unit			£39	3	5
Current at 2d. per unit			20	9	6
¾d. per unit on the 7d. rate			4	3	11
½d. per unit on the 2d. rate			5	2	4
Renewals of lamps			2	0	0
				£70	19 0

Now, let us assume that at the end of the four years this consumer decided to purchase the installation, the cost would then be as follows :—

Brought forward from last account			£70	19	2
Cost of installation	£15	3 9			
Less 10 per cent. depreciation	1	10 4			
			13	13	5
Interest on the amount paid extra per unit, the whole being averaged			1	2	6
				£85	15 1

Instalment Plan.—Taking the same case again, the cost will be as follows :—

Current at 7d. per unit	£39	3	5
Current at 2d. per unit	20	9	6
Renewals of lamps	2	0	0
2½ per cent. for supervision of "undertakers"	0	7	7
10 per cent. of capital paid on completion	1	10	4
16 quarterly payments of the remainder	13	13	5
Interest on unpaid portions at 5 per cent.	1	8	4
Interest on paid portions as accumulated	1	11	0
Depreciation at 2½ per cent. per annum	1	10	0
		£81	13 11

A comparison of the three systems shows the following result :—

Free wiring	£85	15	1
Instalment	81	13	5
Cash payment	81	7	8

In each case the installation is the property of the consumer at the end of the four years. This, I think, shows that the consumer is a distinct gainer by adopting the instalment plan. Who would pay cash when such a means is open to him of having his premises fitted up and inspected for such a small extra payment?

The above instances show that in the majority of cases the instalment plan of payment is by far the most beneficial to the consumer, although it does happen that in some cases when a consumer is a short-hour user and does not desire to purchase that the free wiring plan is the best for him. Although the helping of a consumer to lighten the first cost of fitting up is a good means of stimulating a demand for electricity, at the same time it is necessary that a low tariff should be adopted, and that such a tariff can be made profitable is easily proved by a glance at the annual returns of lighting stations. Street lighting is also a department that requires special inducements to ensure its adoption, and this end is most easily obtained by a low tariff—of, say, 2½d. per unit inclusive of all charges of maintenance.

Tramways.—This department is an important one, and one that every municipal electrical engineer should try and combine with a lighting system if possible. The bogey one so often hears of now—the putting forward of the benefits of having a separate supply station—can generally be traced to self-seeking on the part of a tramway committee, and perhaps of an official as well, who, forgetting that both departments belong to the same body, wish to be able to say that their department is separate from all others. Would they talk in the same way if it were a question of supplying a company with current for the running of their cars? If a separate station can generate current cheaply the combined station can do so equally well, for, although on paper it may be supplying at a lower rate than it is costing to produce, the benefit of the extra long-hour load is cheapening the whole cost of production, and therefore enabling an extra profit to be made on the lighting supply. This can be done without any extra cost to the tramway department. The acquisition of a 16-hour load is a valuable adjunct, and even this can be increased by utilising the track at night-time for running cars for removing the town's refuse that has been collected during the day, and thus save the corporation a large amount of carting costs.

Stationary Motors.—By offering current on a low sliding scale of from, say, 2d. to ¾d. per unit, coupled with a system of hiring motors, a very profitable demand should be obtained.

There is a class of consumer very difficult to obtain, as it comes under the maximum lighting rate, and which I have often heard engineers say they are better without—I refer to the large consumer with a short-hour demand, whose lighting is required only at the peak of the load. Why should not this lighting be turned into a long-hour demand with a small demand in kilowatts? I venture to give an instance of how this might be brought about—at any rate, in continuous stations—with the aid of a storage battery and a motor generator. For example, a mill or factory using, say, 1,000 16 c.p. lamps at 100 volts. I would instal a battery of about 1,000 ampere hours and a motor generator of about 6 kw. The capital cost of this with switch gear would cost, say, £630. Assuming the daily average demand to be 1½ hours, the current required per annum would be 27,375 units, which, at a charge of 7d. and 2d., would amount to £608. 6s. 8d. In place of supplying current direct at the above prices, suppose we do so on the following plan, using the battery and motor generator mentioned above. The cost per annum should then work out as follows :—

Interest on capital outlay at 5 per cent.	£31	10	0
Maintenance of battery at 6 per cent. per annum (taking the cost of battery at £500)	30	0	0
Depreciation on remaining portion of capital at 2½ per cent.	3	15	0
Proportion of labour looking after plant	30	0	0
Oil, water, waste, &c.	5	0	0
Units used by motor generator in keeping battery charged, assuming a 50 per cent. efficiency, 54,750 units at, say, 1d. per unit	228	2	0
Total	£328	7	0

It will be seen that a saving of £279. 19s. 8d. is made, and the central station obtains a large demand in current at a very small demand in kilowatts. What follows may perhaps seem irrelevant to the subject of this Paper, but I venture to give an idea of the profits that might be derived if—a big If—consumers could be brought to the same way of thinking as the engineer. I am taking my own town as an example, and I instance only existing cases and those promised. The capital cost will be very close to the figures given, all contracts having been let and an ample amount allowed for contingences—

Kilowatt capacity of the station	1,800		
Deducted for reserve	300		
Net amount available for use	1,500		
Capital cost per kilowatt	£60		
400,000 30-watt lamps connected to the mains, each using 20 units per annum, at the average price of 4½d. per unit —800,000 units	£15,000	0	0
120 arc lamps 500 watts each, burning 3,700 hours per annum, and using 222,000 units, at 2½d. per unit, inclusive of maintenance	2,312	0	0
300 kw. in motors, including six mills and factories for lighting purposes, and 70 kw. in motors in a cold storage running 24 hours per day. The average demand is taken at 10 hours and the average price per unit at 1¼d.—1,095,000 units	5,703	0	0
26 miles of tramways running 1,226,000 car miles per annum and using 1 unit per car mile at 1½d. per unit	7,665	0	0
Total	£30,680	0	0

The load factor works out at 25·44, and with so high a one no difficulty should be found in obtaining a total cost per unit of not more than 1·25d. per unit. This would give a total cost on the above output of £17,420. A profit of about 12 per cent. is made before setting aside interest and depreciation and about 7 per cent. after paying all charges. I have endeavoured to place all the figures on a safe basis: at the same time I can see no reason why the total costs should not be brought down to 1d. per unit. I trust this short Paper may be the means of obtaining many suggestions for increasing the demand for electricity, especially that class which will increase the load factor.

CORRESPONDENCE.

LONG-DISTANCE POWER TRANSMISSION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have read Prof. Perry's letter in your issue of June 15. Instead of saying, as before, that it is impossible in a transmission line to get an efficiency of less than 50 per cent., he now says that this is impossible to a competent engineer. If he will further limit this statement to transmission lines *without boosters* he will have uttered a truism which everyone accepts. But the statement is untrue if boosters be used.

He very frankly admits that, in my letter which you published on June 8, I had succeeded in detecting certain erroneous data which he had made use of when criticising Table II. of my Paper given to the Institution of Electrical Engineers. But his last letter accentuates a serious mistake, which in his previous letter had escaped my notice.

In the second line of my Table II. the following question is answered: *What weight of copper* (per horse-power delivered) *is required for the efficiency 12 per cent.* under certain specified conditions? There is only one answer to this question, and it is *half a ton*, as stated in Table II.

Prof. Perry tries to prove this table wrong by answering incompletely a different question, viz.—*What efficiency can you get with half a ton of copper* under the specified conditions? There are two correct answers to this question, both of which

Digitized by Google

happen to be given in my Table II. One is 12 per cent. (given exactly in the second line of Table II.). The other answer is about 70 per cent. (given in Table II. by interpolation at the fourth line). Now, Prof. Perry publishes a table in which the former value is headed "According to Prof. Forbes," and an approximation to the latter value is headed "Correct figures," although both values are indicated in my table.—Yours, &c., GEORGE FORBES.

London, June 18.

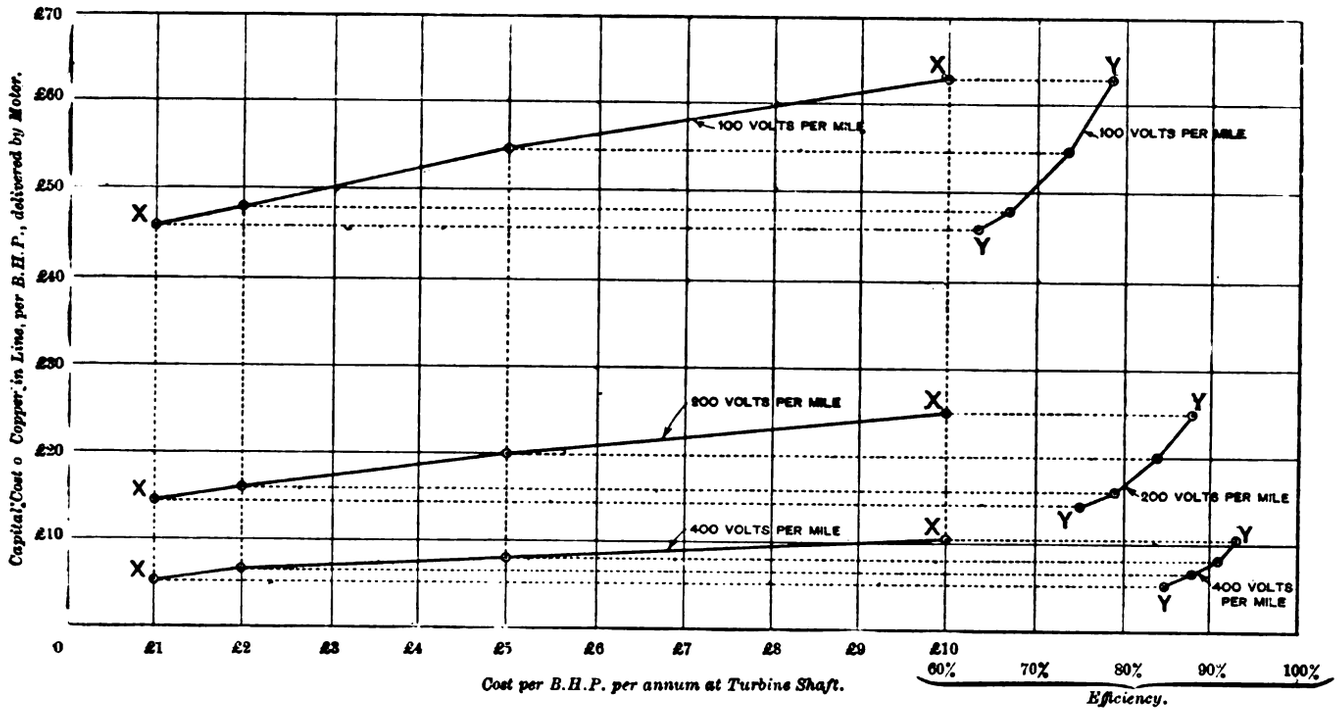
TO THE EDITOR OF THE ELECTRICIAN.

SIR: It would seem that Prof. Forbes' position in this matter is that, by the employment of boosters, we are able to waste as much power as we please in transmission, even to the extent of three or four times the power received at the motor end of the line. It is difficult to see that the booster serves any other function than to enable us to obtain nearly perfect regulation of the E.M.F. at the receiving end, no matter how great the loss in transmission be made. Why, then, should not the same principles which have hitherto guided us in deciding how much power to waste in the line, as against paying interest and depreciation on more copper, still guide us under the new conditions? No doubt Prof. Forbes only proposes to go below 50 per cent. efficiency when the cost of power is extremely small. The question is whether it is ever to be had, in any part of the world, so small as to warrant going down to an efficiency of less than 50 per cent.

Mr. Kapp has long since given us a means of working out in a convenient way—and one which takes account of all the factors concerned—a partial answer to this question. I refer to the investigation on page 377 of his book on the "Electric Transmission of Energy" (fourth edition). The convenient fact that the efficiency (η) and the total amount of copper in the line (t) are unaffected by the length of the line, provided the generating voltage be increased in proportion to the length, enable us to tabulate a few results, which will cover a large number of cases, by stating the generator voltage as so many volts per mile of transmission line. In the curves marked XX, attached herewith, the total capital cost of copper per B.H.P. delivered by the motor at the receiving end is plotted with the annual cost (p) of a B.H.P. as taken from the turbine, or steam engine, shaft. The curves are all on the same basis as regards interest and depreciation (q), which is taken at 10 per cent. on generator, motor, and line copper; also as regards the price of copper per ton (K), which is taken at £80 per ton (this value is now too low, the curves having been drawn some years ago, but the result is not seriously affected by the value taken for this item); also as regards the capital cost (g) of the generator, which is taken at £8 per E.H.P. The set of curves marked Y represents the result of plotting efficiency of transmission (η) with capital cost of line per H.P. delivered by motor.

It will be noticed that there are three curves in each case, viz., 100, 200 and 400 volts per mile. Also that 50 per cent. efficiency is not reached, even with water power costing only £1 per annum. The instance given by Prof. Forbes, where power is to be transmitted over 100 miles at 10,000 volts, comes, of course, on the first of these curves. The curves are obtained by ascertaining, in each case, the most economical current (see Kapp's formula) for a particular voltage. This current determines the back E.M.F. of motor; from this we get the efficiency of transmission, and from this, again, the section of copper in the line.—Yours, &c.,

Old Charlton, June 16. A. M. TAYLOR.



NOTE.—These curves show Capital Costs and Efficiencies for any possible length of line. To obtain Tons of Copper per B.H.P. of Motor divide ordinates by 80. q = 10 per cent. (interest and depreciation), g = £8 per E.H.P. (of generator).

CURRENT-RUSHES INTO TRANSFORMERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In Mr. Clinker's article on the above subject, appearing in this week's issue of your paper, there is absolutely no reference to, or acknowledgment of, the work of previous investigators in the same field. It is, no doubt, one of the easiest things in the world nowadays—when so much experimental work is being done everywhere—to overlook the work of others. It may, therefore, interest Mr. Clinker to know that the explanation of current-rushes advanced by him as "probable" appeared in the pages of *The Electrician* as far back as 1894 (Vol. XXXIII., pp. 229, *et seq.*). If Mr. Clinker cares to take the further trouble of referring to Vol. XLIII. of *The Electrical Review* (August 26th and September 2nd, 1898), he will find an account of some experiments closely resembling those described in his own article; he will also find references to the work of other investigators. It seems a pity that Mr. Clinker did not refer to his *Science Abstracts* before publishing his article; he might in that case have been spared the disappointment of finding that he has been forestalled by others.—Yours, &c.,

Liverpool, June 16. ALFRED HAY.

LEGAL INTELLIGENCE.

Electric Construction Co. (Ltd.) v. Imperial Tramways Co. (Ltd.) and British Thomson-Houston Co. (Ltd.) (the 3rd parties.)

The hearing of this application was resumed on Monday.

At the conclusion of Mr. Fletcher Moulton's address, reported in our last issue,

Mr. BOUSFIELD said that apart from the question of the springs, the sleeving mentioned in the specification was of great importance. The whole object of the invention was the mode of attachment of the motor so that the up-and-down movement of the car should not harm it. To get that it was necessary to have one end sleeved on to the axle. Nobody could fail to see that the purpose of sleeving at one end was to allow freedom of motion at the other. The sleeves described in claim 1 meant sleeves to permit of that kind of motion.

The MASTER OF THE ROLLS: In his judgment Mr. Justice Cozens-Hardy had used these words: "This being the construction which I place upon the specification. It was faintly, if at all, argued that the patent could be supported"; but what I want to know is this, if we should be of opinion that the first claim does not include springs or their equivalent, but was independent of the mode of attachment, do you argue that the action proceeded in the Court below on the basis that the patent could not be supported?

Mr. BOUSFIELD said he could not accept that view.

The MASTER OF THE ROLLS: You still say that the patent can be supported although the first claim has nothing to do with springs.

Mr. BOUSFIELD said it was true the whole fight was conducted on the assumption that the first claim implied springs, but where they were met by an alternative which did not include springs, there it was clearly put that even in that case it was not anticipated. The fact that the learned judge used the words "faintly argued" positively showed that the alternative was put before him, and one judgment having gone against them they were now more anxious to make good before their lordships their contention as to that alternative.

Lord Justice RIGBY: Your own witnesses say that springs are essential, and that if claim 1 did not include springs the other four things are not within the invention.

Mr. CRIPPS: That is how we put our case.

Mr. BOUSFIELD: Then I am entitled to complain that my learned friend did not bring it home rather more closely to the witnesses. I do not, however, intend to argue that springs, or what would amount to an equivalent, are not essential to our invention.

The MASTER OF THE ROLLS: The difficulty seems to be that apart from Sprague there is nothing to show that it may not have been thought perfectly good to support the motor so that the relative positions of the armature and the field-magnets would not be changed, and the mechanical connection between the motor and the driving-axle would not be disturbed.

Mr. BOUSFIELD said the inventor had got a problem before him. He stated in the specification the nature of the problem, and then he explained how he was going to solve it.

The MASTER OF THE ROLLS: You have got to state what your specification means.

Mr. BOUSFIELD remarked that the specification was a plain statement of the object of the invention, and they must take the claims in connection with what was the real purpose of the invention. They must be read in conjunction with what had gone before in the specification. He admitted frankly if he had to argue this first claim on the supposition that it was a claim for a particular combination used in a manner inconsistent with the use which the patentee professed to make of it he could not hope to succeed, because it was not only anticipated by Sprague but by half a dozen other people, but if he took the claim as a combination to be used so as to effect the purpose of the patentee, and which was consistent with the description which went before it, then he felt that his difficulties if they did not vanish were at any rate very much lessened.

The Master of the Rolls asked Mr. Cripps to direct the attention of the Court to that part of the evidence which bore upon how the case was conducted in the Court below.

Mr. CRIPPS said that in the Court below, quite outside Sprague or any anticipation of any kind, the witnesses called by the plaintiffs themselves assented to the proposition that, apart from the springs, there was no invention at all. The learned judge, upon that, held that the first claim excluded the springs, and therefore, as he said, it was faintly if at all argued that the specification could be supported. Mr. Moulton, in the Court below, took his stand on claim 3, which included springs, and endeavoured to show that in the light of that claim springs could be read into claim 1.

The MASTER OF THE ROLLS: That was their main argument here.

Mr. Cripps then read those parts of the evidence directed to his argument, that if springs could not be read into claim 1 there was no invention.

Mr. Moulton shortly replied.

The MASTER OF THE ROLLS, in giving judgment, said that this was an appeal from the judgment of Mr. Justice Cozens-Hardy, who had decided, upon the construction he had put on the first claim, to certain letters patent, that the patent could not be supported. Speaking of himself, he (the Master of the Rolls) felt very considerable sympathy with the patentee, because this was a case not without precedent, in which the real substantial anticipation was a disclosure of the patentee's own invention in a description previously sent from the United States of America by the inventor and communicated to Great Britain. But if they came to the conclusion, as in his judgment they were driven to do, that the claim in the specification, so long as it stood, was too wide and was old, they had no alternative but to accept the position described by Mr. Justice Cozens-Hardy that the whole patent was invalid. The patent related to the means of connecting electric motors with the wheels which they were to drive. It was to be observed, and he thought it was a very important matter in the present case, that the Court had no statement made to it as to what the existing state of the knowledge was, which they had to bear in mind in construing the claim in the specification. All the Court had to guide it was the nature of the specification itself. Now the object of the invention was stated in the opening passage of the complete specification: "This invention relates to electric motors mounted upon railway cars or carriages for the purpose of propelling the same, and its object is to so arrange and support the motor that the relative positions of its armature and field-magnet will not be changed and the mechanical connections between the armature and the driving axle will not be disturbed by any movement of the car body or carriage body on its springs, while at the same time the driving-axle is relieved of dead weight. In accomplishing those objects the yoke or back piece of the field-magnet of the motor is hung from a cross-piece of the truck of the car or carriage by heavy springs; or from the car body itself in case of a street car or other vehicle having no truck." The next few paragraphs of the specification described certain proportionate parts of the invention. He passed now to observe that it had been contended on behalf of the appellants that the Court was to assume for the purpose of considering the specification that the whole, and if not the whole the real substantial merit of the invention rested on the fact that the motor was suspended by springs from the car, and that the Court was to assume both from the directions given by the patentee in his specification and from such reasoning as their lordships could bring to bear upon it themselves, that it would be utterly inconsistent with any application of the invention that the motor should be suspended by anything other than springs or their equivalent. Speaking for himself he did not think there was anything on the face of the specification which enabled anyone to form that conclusion. His lordship then referred to claim 1 of the specification, "The motor of an electric railway car or carriage having its field-magnet centred or sleeved upon a driving-axle, its armature supported directly upon the said field-magnet, and having a shaft separate from the driving-axle and gearing communicating motion from the armature shaftt to the driving-axle, substantially as hereinbefore described." That first claim enumerated what appeared to be the essence of the invention, excluding the springs in terms. It had no reference to a spring suspension. Then, it was said that the Court by reason of the words "substantially as hereinbefore described," must read into claim 1 the supporting springs. He thought that would be a construction the Court had no right to adopt. His lordship had read the whole of the proceedings in the Court below and looked through the whole of Mr. Moulton's speech, and from the way the cross-examination was conducted he could not see any substantial indication that the plaintiffs in the Court below attempted to justify the first claim, if it were assumed that the springs were not included in it. He thought, in the present case, on the face of the specification, that the Court must come to the conclusion that the patentee, whatever he wanted to do, did claim as against the public to include as within the ambit of his invention a claim to a motor in which the field-magnet was centred or sleeved upon a driving-axle, its armature supported directly upon the said field-magnet, and having a shaft separate from the driving-axle and gearing communicating motion from the armature shaft to the driving-axle, and this whether it was supported by springs or not. That being so, on the evidence given in the Court below, he came to the conclusion it was impossible to say that that particular combination excluding those springs was new. He thought himself it was clearly shown in the drawings of Sprague's invention, and so shown that any competent electrician could have understood it at once. Here no witness had said that those drawings would not have disclosed to a competent electrician the four essential features of the first claim. That was published in England before the date of the application for a patent, and that being so, it was not possible to support the first claim. For those reasons he thought that Mr. Justice Cozens-Hardy was right, and that the appeal should be dismissed.

Lords Justices Rigby and Collins gave judgment to the same effect, and the appeal was dismissed with costs.

National Telephone Co. v. Tunbridge Wells Corporation.

This case was heard in the Queen's Bench before Justices Grantham and Channell on Monday, and raised a question as to whether a stipendiary magistrate or a county court judge has, since the passing of the Telegraph Act, 1892, any jurisdiction to hear and determine an appeal from a refusal of the highway authority to allow a telegraph company to open up streets for the purpose of laying wires or tubes. By two deeds of 1881 and 1896, made between the Postmaster-General and the National Telephone Co., the company were authorised to work and use certain forms of telegraph for the purpose of transmitting telegrams within the borough of Tunbridge Wells. By a deed dated 1896, and made between the Corporation of Tunbridge Wells and the Telephone Company, the Corporation consented to the company exercising within the borough such powers as might from time to time and at any time be delegated by the Postmaster-General to the company, in pursuance of the provisions of sec. 3 of the Telegraph Act, 1892. This deed went on to say: "It is expressly agreed that the consent contained in the preceding clause is given upon the following conditions: (1) Except as regards the work mentioned in the schedule, the company shall not exercise any of the powers conferred on the Postmaster-General by the Telegraph Acts 1863 and 1878, in respect of which the consent of the Corporation is required under the said Acts, without obtaining the further consent in writing of the Corporation, to be from time to time given to the specific works for the time being proposed to be carried out under such powers, it being intended that the general consent contained in the preceding clause is not to operate to relieve the company from the obligations of obtaining

Digitized by Google

the particular consent of the Corporation to such specific work as required by and provided for in the said Acts." Clause 10 of this agreement contained a reference of all disputes under its terms to two arbitrators and an umpire. The company wished to open a street and lay telephone wires and to execute works not mentioned in the schedule to the last-mentioned deed, and applied for the consent of the Corporation. The Corporation refused, and the company contended that under sec. 4 of the Telegraph Act, 1878, they had the right to refer the "difference" to the county court judge. The county court judge, while expressing the opinion that he had jurisdiction to hear and determine the difference, refrained from doing so until the hearing of this motion, which was for a prohibition, upon the ground that since the Telephone Act, 1892, sec. 5, the county court judge had no further jurisdiction in such cases.

Mr. JOSEPH WALTON, for the Corporation, having read the special case stated by the learned county court judge,

Mr. CRIPPS, Q.C., and Mr. J. CASSELL, for the National Company, submitted that the consent required by the deed of 1896 meant consent subject to appeal to the county court judge. They further contended that the county court judge was constituted an arbitrator, and that prohibition was not the appropriate remedy.

Mr. Justice GRANTHAM said there was no doubt what their judgment should be. The National Telephone Co. had not brought themselves within the Act of Parliament which gave general powers to carry on these works in the way in which it had been claimed by the National Telephone Co. There was not much doubt as to what really was the history of this legislation. In 1878 everything was in the hands of the Crown through the Postmaster-General. Then pressure was brought to bear upon them and they consented to delegate some of their powers, but the moment they did that and allowed these works to be carried out by a company, they very properly changed their *modus operandi*. During the time that it was a Crown monopoly and the Crown had a right to do this work it was considered just that the judicial authorities of the Crown should be invoked to determine any differences that arose between the Crown and the public authorities. The Postmaster-General consented to do this work in Tunbridge Wells. By the Act of Parliament it was provided that, supposing there was a difference between the 'Postmaster-General and the authorities at Tunbridge Wells, some tribunal must determine who was right. It being a question of the right of the Crown to do this, the Legislature decided to invoke the aid of the judicial authorities of the Crown—the county court judge or the stipendiary magistrate. Then came the Act of 1892, whereby these powers were delegated. The moment private individuals carried on this work the right which the Crown had to call in the aid of the judicial authorities ceased, and more power was given to the authorities in whose district the work was to be done. The urban authorities were given a power of veto. Their consent must be obtained to exercise, first, the powers to be delegated, and then there was a right to say in what way they would consent to these powers being exercised. The Tunbridge Wells authorities gave a general consent, but subject to the general terms of the agreement, that the consent was only to do the work thereby agreed upon and set out in the schedule, and before any other work was done they must obtain the further consent of the local authority. The parties to the agreement rightly understood what their rights and liabilities were. Under the Act of 1892 this agreement was expressly and properly drawn to give such rights as the Corporation intended to give in the first instance to the National Telephone Co. reserving to themselves the right which, by the Act of 1892, they had power to reserve. The National Company, were bound by the terms of the agreement, and had no right to say the county court judge was the proper tribunal to determine any difference which had arisen between the parties.

Mr. Justice CHANNEL concurred, and the application was allowed with costs.

Corporation of Huddersfield v. the National Telephone Co. (Ltd.).

This case came before Justices Grantham and Channell in the Queen's Bench on Wednesday on an application by plaintiffs for a writ of prohibition directed to the county court judge of Huddersfield prohibiting him from hearing an application made to him by the National Telephone Co. by way of appeal from the refusal of the plaintiffs to allow the company to open up streets for the purpose of laying wires or tubes.

After hearing Mr. Macmorran, Q.C., as to the nature of the appeal, Mr. Justice Grantham stated that having looked at the agreement on which the motion was based, it seemed on all fours with the case of the National Telephone Co. v. The Tunbridge Wells Corporation decided on Monday.

Their lordships, in the result, after hearing Mr. Cripps, Q.C., for the Corporation of Huddersfield, decided that as the case raised practically the same point as the other case, the prohibition would be granted with costs.

British Insulated Wire Co. v. Dublin United Tramways Co. and National Conduit and Cable Co. (of New York.)

In the Chancery Division, Dublin, on Tuesday, before the Vice-Chancellor, Mr. Blood, Q.C., applied on behalf of plaintiffs for liberty to deliver to defendants and each of them interrogatories, and that the defendants be ordered to make a full and satisfactory affidavit of documents, setting out amongst other documents, particularly invoices, bills of lading, consignment notes, receipts, &c., and documents relating to any portion of certain cables sold by the New York company to the tramway company in infringement of plaintiffs' patent. The action was heard in Nov., 1899, to restrain the infringement of certain patents which plaintiffs owned for the manufacture of cables for electric traction. On Sept. 2, 1896, plaintiffs' patent expired. The judgment of the Vice-Chancellor was that defendants admitted they had infringed plaintiffs' patent of 1884, and submitted to an inquiry for damages. The Court ordered an inquiry at Chambers as to what damages the plaintiffs had sustained, limiting it to any portion of the cable manufactured according to said patent received by the defendant tramway company prior to Sept. 2, 1898. Plaintiffs were unable to file their affidavit before the chief clerk without the information which they now sought to obtain.

Mr. S. RONAN, Q.C., for the tramway company, said the time had not yet arrived for defendants to file their affidavit, and it would be presumed that in their answer they would state how much they got. The New York company had an American patent which justified everything they did in America, and the plaintiffs had an English patent which only prevented acts in infringement in the United Kingdom. The tramway company had arranged with the American company to deliver a portion of the cable, but that it should not be delivered in this country until after Sept. 2, 1898, the date of the expiration of plaintiffs' patent. By mistake a small amount was delivered in this country prior to that date, and the tramway company immediately admitted liability for the amount. The real object of this motion was to extend the decree to everything put on board at New York prior to Sept. 2, which was contrary to his lordship's judgment.

The VICE-CHANCELLOR did not think he had gone the length of holding that the defendants were only liable for cables received in Dublin.

Mr. RONAN asked for an adjournment of the motion that he might serve notice to amend the decree.

The VICE-CHANCELLOR said it would be necessary to have this question decided. If the delivery on board ship at New York was a receipt by defendants, then they were liable for an infringement *quoad* those goods. It was not so much to amend the decree as to construe it.

The application was granted.

Stephens v. Mather & Platt (Ltd.).

An action was heard this week before Mr. Justice Lawrence in the Queen's Bench Division, being a claim by Mr. Hilliard Stephens for an account of all orders executed by Mather & Platt (Ltd.), in respect of the business of Dowson, Taylor & Co., engineers, of Manchester, in their district for 1899. The plaintiff claimed 2½ per cent. commission on the whole of the London turnover. The jury returned a verdict in his favour, and an account was therefore directed to be taken.

PARLIAMENTARY INTELLIGENCE.

MUNICIPAL TRADING.

The Lords and Commons Joint Committee on Municipal Trading held another sitting on Friday last, the Earl of Crewe presiding.

Mr. CHANDOS LEIGH, Q.C., counsel to the Speaker of the House of Commons, explained the nature of his duties in relation to private bills. In examining them he had to be careful that no bill involving general taxation, or which, in his judgment, should be introduced as a public bill, should be introduced into the House of Lords. As a rule, electric schemes were dealt with by the Board of Trade, but there had been some notable exceptions this year. An instance of opposition on second reading occurred in the case of the General Power Distributing Co.'s bill. That bill originated in the House of Lords, and was passed by the House, but so late in the session that it could not get through the Commons. It was thought very hard it should have to be begun *de novo* in the next session; the bill was suspended and taken up at the same point in the next session. In the result the House of Commons threw the bill out after it has passed the House of Lords. This session there was a group of seven electric distribution bills, which, after a long discussion, were referred to a special—not a hybrid—committee, with Sir James Kitson as chairman. Five of the bills had been heard, but the Committee did not intend to give a decision until they had heard the whole. The general principle in these bills was that where sufficient public advantage was shown power might be given for the supply of electric energy over an area embracing the districts of numerous local authorities. In some of these bills restrictive clauses would be inserted. Thus one provided that where local authorities already had power the company should not within the district of that authority supply electricity except to wholesale consumers; and another clause gave the local authority power to exclude the company from supplying if the authority were ready to take the supply in bulk and distribute it themselves. All unopposed bills were examined very closely, and a very careful report drawn up in regard to them. In the House of Lords the powers of the Chairman of Committees with regard to these bills were autocratic; if he liked he could cut a clause out, and the House of Commons Committee could not re-insert it. Witness read unopposed bills to discover novel clauses which might be objectionable in going further than the general law. If he saw any strong clauses in a bill he would direct attention to them. Thus in the Rochdale bill the Corporation took power not only to create ice stores but to make and sell ice. That was, to his mind, a clear case of municipal trading. That clause was unopposed; so witness went to the Chairman of the Committee dealing with the bill, and directed his attention to it in order that it might be dealt with by the Committee.

The CHAIRMAN: So far as you know has the power ever been given?—No; it is a totally novel power to me. Continuing, he said a most important matter was the power which corporations sought to raise money by bills and promissory notes. The ordinary way of raising money by a corporation was to issue stock.

Digitized by Google

Lord ROTHSCHILD: Suppose they were unable to raise a loan, what would they do?—They would have to come to Parliament to be authorised to raise the loan unless they had got unexhausted borrowing powers. No doubt corporations, in some cases, had very large overdraughts from their bankers. The first case of allowing money to be raised by promissory note and bills, which was a more straightforward method, was that of the London County Council some years ago. The difference lay in the fact that the London County Council were subject to Government audit, while the old municipalities elected their own auditors. Consequently great care had to be exercised in this matter. He could not say whether the banks would be able or not to recover overdrafts allowed to municipalities.

Mr. HOBHOUSE: Are not these overdraughts shown on the municipal accounts?—They ought to be. That rather supports me as regards watching things very carefully.

A NOBLE LORD: You do not assert of your own knowledge that any corporations have borrowed in excess of their statutory powers by overdraft or otherwise?—I cannot say that. I know that there have been overdrafts to a considerable extent; there may have been unissued borrowing powers. He thought it would be better to allow these clauses relating to bills and promissory notes, provided the city or town had sufficient status both in population and finance to warrant it being done. On the question of allowing an individual trader *locus standi* to oppose a trading scheme of a corporation, he said, as a general rule, the *locus* was not allowed. This was a point on which some guidance was wanted for the Committee. The general principle acted on in one case at least was that where there was anything which affected the interest of the general travelling public, the 'bus companies concerned were allowed a *locus* to oppose.

The CHAIRMAN: It is quite clear you would not give a *locus* to any individual trader to say he was injured by municipal trading?—I do not think so. While recognising that no private company could have carried out water schemes such as those of Manchester, Birmingham, Liverpool, and the Derwent Valley he rather deprecated the practice of municipalities acquiring water and gas companies against their will and consent. This practice had enormously increased in the last few years. Municipalities which had never initiated or invented anything in reference to gas, tramways, or electric lighting, had yet, in a manner, forced the companies which undertook those matters to sell when their concerns became flourishing. He knew of no case in which a municipal authority had sought to acquire a gas undertaking except it had been in a sound position. He stated, from information obtained from private sources, that between 1878 and 1897, while the increase of population had been 21 per cent., the increase of rates had been 175 per cent., and of local indebtedness 220 per cent.

Mr. SYDNEY MORSE, chairman of the Municipal Trading Committee of the London Chamber of Commerce, said the subject of inquiry had been very fully discussed by the Committee of the Chamber, and upon their report a resolution was passed by the Chamber declaring that the scope and sphere of municipal enterprise in opposition to private enterprise ought to be defined. The Municipal Corporation Act of 1835 was intended to place corporations in the position of trustees, and to restrict their use of corporation funds to certain definite purposes. Local authorities endeavoured to keep down the rates, and it appeared to his Committee that they desired to carry on undertakings outside their areas in order to make a profit and so reduce the rates. In regard to the Tramway Act, he complained that the consent of the local authority being a condition precedent to any scheme, private enterprise in this direction was often hampered by the local authorities seeking to impose hard conditions on the promoters. The intention in giving power to the local authority to purchase at the end of 21 years, was that when the purchase had been effected the authority should lease the line and not work it. Applications in regard to electric light were generally made by provisional order. It was necessary to prove to the Board of Trade the consent of the local authority, and although the Board of Trade had power to dispense with that consent, until last year they had never used that power where the question was one simply of granting or not granting; they had used that power in regard to matters of detail. In the early days, say in 1889, when electric lighting was not so far advanced, it was not difficult to get consent; but as it became more of an assured success so it became more difficult to get consent, and now if one went to even a very small district very onerous terms were put upon the promoters. Where the corporation owned the gas works it was often argued before the Board of Trade that they had invested a large sum in gas which might be endangered if electric lighting was allowed. Thus the progress of electric lighting had been very seriously retarded. Further, the electrical industry had been placed in a very unkind condition as regarded other industries. Gas and water obtained a freehold, as it were; but electric lighting companies' undertakings had been limited as to consent, price, and terms of purchase, though it had been, he supposed, quite as important an industry and as difficult to introduce as any of the others. As showing how municipal trading was increasing, he said municipalities in the last two years had introduced bills in relation to railways, canals, tramways, harbours and tidal waters, for which they had asked for a total of 70 millions of money, whereas in the previous nine years the total figure was only 37 millions. With regard to tramways he said in many cases mechanical powers had been given to a company, but practical operations prevented by the refusal of the consent of the local authority; and nowadays consent was always refused on the ground that the local authorities were anxious to work the lines themselves. The tramways had certainly not had fair play. In introducing a new tramway capital had to be embarked, but it had to be kept intact and a living wage made because at the end of 21 years the promoters were certain not to get back their original capital. No money could be spent on improvements or extensions, and the promoters had to get on as best they could, as compared with the authority, which had a freehold and could look to the future to repay losses of the present moment. If powers were given, as had been proposed, to municipalities to work tramways outside their districts, they would be actual competitors with the companies.

On Tuesday Mr. S. MORSE, continuing his evidence, said the opinion of Municipal Trading Committee of the London Chamber of Commerce was that the action of municipalities in trading should be restricted to matters undertaken in the public interest, and not with a view to profit, and therefore matters in respect of which it was reasonable that a rate should be made. Water was a thing which it was to the interest of everyone to deal with in a proper, wholesome, and pure manner, and the Committee of the Chamber of Commerce thought it reasonable that a rate should be made for giving a pure supply of water. They were of opinion that if municipal trading were allowed it must have the effect of abolishing the private trader. Where trading concerns were in the hands of local authorities there was no incentive to progress, and no inducement to take advantage of new inventions. If the principle of trading by municipalities were once allowed it would be extremely difficult to limit the class of trading permitted. The distinction he drew between water and lighting was that it was essential from a sanitary point of view that every house should have a good supply of water, but it made no difference to one householder whether his neighbour had any light at all or used candles or lamps. He did not see why a man should be compelled to contribute towards the provision of light for his neighbour, though he did see why he should be compelled to contribute towards the provision of water, the general use of which was necessary in the public interest. The mere fact that local authorities had power to veto companies' tramway and electric lighting schemes had, he thought, injured trade in this country. To such an extent was this the case that we had to get a large quantity of our tramway and electrical plant from abroad.

Mr. S. B. PROVIS, permanent secretary to the Local Government Board, stated that during the past five years the Board had sanctioned loans for electric lighting purposes amounting to £5,726,000, of which £5,138,000 were to town councils and £588,000 to urban district councils. The whole of these loans were sanctioned under the general law, but during the same period £1,051,000 was borrowed under local acts.

The Committee then adjourned till to-day (Friday).

THE ELECTRIC POWER BILLS.

THE LANCASHIRE COMPANY'S BILL.

The Select Committee of the House of Commons on Electric Power Bills resumed its investigation on Monday, Sir J. Kitson presiding.

Mr. WILLIAMS addressed the Committee in support of the petition of Southport Corporation against the bill. He said the proposed area of supply included hundreds of square miles of agricultural land which would be absolutely useless for the company's purposes. The estimate put forward by the promoters respecting the load factor appeared to be extremely sanguine, and yet, if it proved to be wrong, the whole scheme would fall to pieces. Southport, as a pleasure resort, was not a suitable place in which to carry on industrial pursuits. The local authorities wanted none of the scheme, and had asked to be excluded from it. There was no probability that they would ever send a requisition to the company for the supply of electricity, and he thought it was clear that unnecessary powers of supply should not be given.

Mr. GRIFFITHS, Mayor of Southport, said the town was a purely residential one, its staple trade being building. The generating stations at Wigan and St. Helens would both be about 20 miles from Southport, and he could not conceive why the powers asked by the promoters in respect of Southport should be given, the district to the north, south and east of Southport for many miles being entirely agricultural. The Corporation of Southport generated electricity very cheaply, and even if the hopes of the company were realised as to the price of supply the Corporation would be able to beat them easily. Why the wishes of an important place like Southport should be set aside on the speculation of a combination of traders passed his understanding. The maximum prices of the Council for electricity supply were 7d., 5d., and 4d., but those were not the prices actually charged.

The CHAIRMAN: You are aware that under the bill you cannot have a supply without your own consent and except on your own invitation. If that be so, where are you injured?—We are injured as the whole wealthy district of Lancashire will be injured in having established in the wealthiest portion of it a protected company of combined traders who will have protected rights and with whom no one will be able to compete except under an Act of Parliament. Of course, if the company expend the large sum of money they propose to expend competition cannot take place. I have not a shadow of a doubt that in the course of two or three years there will be a great improvement in the manufacture and distribution of electricity, and if counties combined to work their electricity, as they sometimes combine for water supply, they could give greater public advantages than it is possible for this company to give. The improvement will, in my opinion, be so great that in two or three years the provisions of this bill will become obsolete.

Mr. C. D. TAITE, electrical engineer to the Southport Corporation, stated that the present load factor of that town was 11·3, but the Corporation were laying down an extensive system of tramways which were to be worked by electric traction, in addition to the existing tramways. This would increase the load factor and reduce the cost to the Corporation of generating electricity for themselves down to about 1·45d. per unit, or 20 per cent. less than the company proposed to charge. It would cost the company 0·4d. per unit for cables to transmit power to Southport. He was not aware that in Germany agriculturists were banding together in order to supply themselves with cheap electricity. He did not know that it would do any particular harm to Southport

Digitized by Google

to grant the company the powers asked for, but the people of Southport objected to the company having powers which they would not exercise.

Mr. BALFOUR BROWNE, Q.C., in opposition to the bill, said he appeared for 13 boroughs in South Lancashire, including Manchester, Liverpool, Oldham, Bolton, Warrington, Wigan, Accrington, Burnley, Salford, and Rochdale. The local authorities in all these important places did not consider the bill would put within the reach of anybody in the district electricity at a cheap rate. The measure sinned in every way. It was a grab at a huge area of country, not for the purpose of supply, but merely to get a foothold there for some ulterior object. The great towns of South Lancashire supplied themselves with electricity, and could do so much more cheaply than the company could. It would do the district serious injury to give a company Parliamentary powers to lay its hand on it, and to object to any local authority, at present without electrical powers, from acquiring them. Too large an area did not tend to the reduction of price. This was shown by the company's own scheme, because they proposed to set up not one undertaking but four. As to the recommendations of the Joint Committee respecting wayleaves, it was not a recommendation that wayleaves should be created promiscuously over a wide area of 1,100 square miles. What the Joint Committee recommended was that power should be given in connection with a generating station outside an area of supply, which of course, presupposed an area of supply in the first instance. The local authority of every great town in this district protested against the company coming in, simply because they knew that there was no public advantage in the scheme. There was no excuse for allowing a company to come in and supply where the municipalities were doing their duty and supplying at very cheap rates. The Corporation protested against wayleaves being granted through the streets of all the towns, the thoroughfares being in many cases absolutely unsuited for laying another pipe or main. The 13 boroughs had already spent about £2,136,000 on electrical undertakings, and they were about to spend £2,100,000 more, so that they had spent or were spending more than the proposed total capital of the company. Liverpool already supplied electricity for traction purposes outside its own area, Manchester supplied Salford and Swinton, and Bolton also supplied for traction purposes outside its own boundaries. The Manchester district of supply had an area of 36 square miles, which was about the limit at which electricity could be advantageously and cheaply supplied. The Corporation was supplying both the outside and inside area at the same price, which, on an average, amounted to 3·33d. per unit, while for power it was 1½d. Liverpool was supplying for lighting at 3·93d., for street lighting at 2·29d., and for tramways at 0·91d. Manchester was doing as well and better than the company could, and, on the face of it, the scheme was wild, ridiculous and absurd.

Ald. LLOYD HIGGINBOTTOM, Chairman of the Electricity committee of the Corporation of Manchester, said he was a mechanical engineer by profession. He acted as chairman of a conference of representatives of boroughs held in reference to this bill, and had been deputed to give evidence on behalf of those boroughs. In the judgment of the boroughs the company ought not to be entrusted with the sweeping powers asked for in this bill. The boroughs felt that the company should not have wholesale powers to break up the streets of any borough in the district. He saw no such public advantage to be gained under the bill as would counterbalance its disadvantages. The cost of laying mains from the generating stations to the towns which the company wished to supply would be so enormous as to absorb the saving that would be effected by placing the generating stations near the collieries. It would be a great inconvenience to have fresh mains laid in the streets of a city like Manchester, where the Corporation already had great difficulty in laying any additional pipes.

Mr. WORSLEY-TAYLOR, Q.C., for the promoters, said that if the Corporation were not properly protected he would see that proper protection was afforded. He asked the witness what objection there was to the bill if the Corporation were properly protected?—The bill was so framed that it could not be altered to properly protect the Corporation, and he declined to reply to a hypothetical question.

On Tuesday, Mr. LLOYD HIGGINBOTTOM, in reply to further questions put by Mr. Worsley Taylor, said Manchester sold electricity at the lowest prices, and if it were possible to introduce Manchester prices all over the County of Lancashire it would be a good thing for the public. The proposed area of supply ought undoubtedly to have the right to get cheap electricity.

Mr. WORSLEY-TAYLOR: Should we have been right if we had come with a bill to take out the rich parts of the area without taking the obligation to supply the poor parts?—I say that you have chosen the rich parts, and have practically left out the poor parts. I say that you cannot supply the poor parts of the district in the north. Witness went on to say that he did not deny that the company would be able to generate power in their proposed generating stations as cheaply as Manchester could generate it, but he did deny that they would be able to distribute as cheaply. Transmission and demand would be the difficulties in the way of the company. In Manchester and district at the present time electric power was not supplied to any of the numerous cotton mills. The Manchester Corporation could supply it, but the millowners did not ask for it, as they could produce it more cheaply themselves.

Mr. A. BROMLEY HOLMES, electrical engineer to the Corporation of Liverpool, said the Corporation purchased their electrical undertaking in 1896 from a company for £400,000. Since the purchase the price charged to consumers had been greatly reduced. To ordinary consumers the present price was 4d. per unit for light; for public buildings it was 3d.; for street lighting, 2d.; for power, 2d. up to 3,000 units per quarter and 1d. beyond. The total capital expenditure of the Corporation on the electrical undertaking had been £769,000, while a further estimated capital expenditure of £380,000 was to be made in the present year. The profits were £9,000 in 1896, £16,000 in 1897, £8,000 in 1898, and £11,000 in 1899. He did not think that the calculations on which the promoters of the Lancashire Electric Power Bill based their scheme were sound. He saw no provision in the estimates for the cost of the construction of transforming stations in the area of supply or for the apparatus that would require to be fixed in these stations, and no provision for duplicating the mains. In his view the proposed load factor of 35 per cent. was imaginary, and could not be attained in practice. His experience was that the company would have to depend for customers on the small consumers of power. The promoters could not possibly give the Corporation proper protection because the Corporation wanted all the room in the streets for themselves. He did not know of any street in which the room would not be required by Liverpool for its own purposes. The largest consumers of power in Liverpool were the printing establishments. The largest motor was 50 H.P. At present they supplied 800 H.P. of electricity for power. If they were called upon to supply the docks with mechanical power it would amount to several thousand H.P. At present they had 50 or 60 customers for power. He was strongly of opinion that if powers were given to the company to lay mains the local authorities should have power of supervision over the laying of them and should have a voice in the construction of the mains, the material used, the covering, and so on. The Corporation of Liverpool was greatly opposed to the principle of the bill, and considered that there would be no advantage to compensate for the inconvenience which it would occasion to the public.

In cross-examination by Mr. Worsley-Taylor, Q.C., WITNESS said that the great harm of the bill lay in the fact that it would empower the company to tear up streets for its mains. Generally speaking, he thought it undesirable that power should be given to a company to supply areas close up to populous centres, which areas could be supplied by the local authorities themselves.

Dr. PANTON, a member of the Bolton Town Council, said the tramway lines of the town had, since the Council acquired them in 1897, been adapted to electric traction. In 1898 the Corporation obtained power to supply electricity in a large district outside the borough from the generating station, which was situated inside the borough. Those powers were at once put into operation. Last year 824,792 units were sold at an average rate of 1·83d. The objections of Bolton Corporation to the bill were based on the serious interference it would cause with the streets of the borough. It was difficult and dangerous even now for the Corporation to find places for their own mains.

Mr. C. H. WORDINGHAM, electrical engineer to the Manchester Corporation, expressed the opinion that no economy would be obtained by increasing the scale on which electrical energy was produced beyond, say, 20,000 H.P. or 30,000 H.P. The only saving would be in the carriage of coal, and that would be swamped by the cost of the mains to the area of supply. It was not practicable to carry electricity for a long distance in this country.

At the conclusion of Mr. Wordingham's evidence, Mr. PEMBER, Q.C., representing the Newcastle Electric Supply Co., stated that an arrangement had been made with the promoters of the Tyneside bill with regard to the Wallsend generating station site, which was scheduled in both bills. The two companies agreed to abide by the decision of the Committee as to who was to have that site. The Newcastle Supply Co.'s bill was to be treated as unopposed in the House of Commons, but in the event of this Committee deciding that the Wallsend site should go to the Tyneside Company that site would be struck out of the Newcastle Company's bill before it passed through the House of Lords.

On Wednesday Sir WILLIAM PREECE said that the electric lighting legislation of this country had met with universal approval. Electric lighting was here developing at a rate of progress greater than in any country in the world, and we were also paying less for it. Electricity was well developed in Lancashire. As to wayleaves, he was of opinion that the local authorities should have a voice in the matter.

Major P. CARDEW said he had considered with regard to the amount of power to be transmitted through mains the question of danger to the public, and of the interruption of supply caused by a breakdown of a main. He considered that a limit of 300 kw. as desirable, though in special cases of trunk mains the limit might be as much as 1,000. He then gave particulars as to the possibility of increasing the danger by multiplying the number of mains through the streets of large towns. He did not think they should refuse to allow the local authorities of a big town to say what route their mains should take on passing through that town. There would not, however, be any harm in leaving the matter to the Board of Trade, who would give ear to the case of both parties. He did not think it necessary to pass through Bolton or Liverpool, and it was not necessary to touch more than two small districts to the east of Manchester to be supplied from the generating station at Old Trafford.

By the CHAIRMAN: The local authority should have the power to lay the mains if they so wished, though the company could not afterwards be responsible for their condition. It might, however, be supposed that the local authority, being solicitous for the safety of their own streets, would take all the greater care. If a jealous local authority laid the mains badly there could easily be an appeal to the Board of Trade. Local authorities had a special knowledge of their own streets, especially with regard to subsoils, and the suitability of mains for such sub-soils. Local authorities should have the power of supervision, with an appeal to the Board of Trade.

Mr. A. H. AITKEN, town clerk of Accrington, said his borough with four other districts to the north and west between Accrington and Clitheroe—which the company proposed to supply—had obtained power to supply the area. The company would have to go through the whole of the Accrington main roads in order to get away up in a corner of Clitheroe. He admitted that the people of Accrington wanted cheap electricity, but stated that they had obtained a provisional order in 1891 and now, practically, had their works finished.

Mr. EVANS, town clerk of Salford, gave evidence against sanctioning the proposal of the company to go into their district.

In connection with the Newcastle Electric Supply Bill, Mr. RICKARDS, Q.C., on Wednesday, informed the Electric Power Bills Committee that arrangements had been come to which made it unnecessary to trouble the Committee to go into the merits of the scheme covered by the bill.

Yesterday (Thursday) Mr. CHARLES HOPKINSON, C.E., was called in support of the petition of the large boroughs, and said that the electric supply which the company proposed to give would be useless for the textile trade, as the cost would be prohibitive. If there was a demand for the kind of power the company could supply it must come from the small industries, in regard to which the cost of a steam installation was very high, and for which the most economical power at present was gas. In his opinion the prospects of the bill were extremely vague. The only elements of economy the promoters could claim were aggregation of works, staff, &c., and the nearness of the coal field; the second consideration did not apply to the generating station at Old Trafford. It would be possible to supply the textile trade with electric power economically if the generating station were next door; it would be more difficult if the station were a mile off, and impossible if it were 10 miles off.

This concluded the case for the opposition.

Mr. WORSLEY TAYLOR addressed the Committee on behalf of the promoters. He had never before come in contact with a more remarkable collection of electrical Baalams than had been put forward as witnesses by the petitioners. The nett result of their evidence was that as soon as any one of them made a point another infallibly came and destroyed it. All the promoters of the bill asked was that they should be placed in a position to offer to supply electric power either to local authorities or to those who had been allowed to set up electrical undertakings with the consent of the local authorities—that they should have the option of giving a supply of cheap electricity with the consent of the local authorities. With regard to the price, he would point out that the schedule included in the bill would only last for seven years, and if at the end of that period it proved to be too high it would be cut down by the Board of Trade. The promoters had voluntarily put into the bill a clause providing that there should be no monopoly, and another giving the local authorities a voice on the question of cable route, with an appeal to the Board of Trade. The promoters had tried honestly and liberally to meet the views of those who they hoped would be their customers, and he appealed with confidence to the Committee to pass the preamble of the bill.

The Committee adjourned the further consideration of this bill.

THE SOUTH WALES BILL.

Mr. PEMBER, Q.C. (yesterday) followed on with the bill of the South Wales Electrical Power Distribution Co. He said it was promoted by a number of gentlemen who were very largely interested indeed in the industries of South Wales, and no financier or contractor had any part or hand in the matter whatever. The total number of factories or undertakings in which the promoters were interested had among them a capital of over £22,000,000. The Company proposed to supply with electricity an area of 1,034 square miles. There were only two local authorities in the whole of the district that were at present supplying electric power. There were only generating stations for some 32 square miles in the district, and only mains laid for 10 square miles. Only 900 odd persons were taking electricity out of a population of 1,000,000, and the average price at present charged was 4½d. per unit. It was obvious that the promoters, being connected with large industrial concerns, would be to a large extent their own customers, and, therefore, the bill stood in a very different position from any other which had been brought before the Committee. The bill proposed to incorporate a company with power to erect three electric generating stations, one at Neath, a second between Pontypridd and Caerphylly, and the third near Pontypool. The measure also provided for a system of mains to be laid partly underground, but partly across country, over which easements were to be obtained. The company was to have a capital of £1,000,000, divided into £750,000 ordinary shares and £250,000 debentures. The area of supply was probably as concentrated in its industrial activity as any in the kingdom its industries including iron works, foundries, tin-plate works, chemical works, and collieries. It was covered with a network of railways, and its shores were covered with ports, while there were some large docks. The manufactures of the district were not, however, in due proportion to the output of coal, though the coal was of the finest quality. The tin-plate industry had largely drifted away to America and other countries, one great factor in the superior position of the foreigner being his superior utilisation of electrical facilities. It was possible by using electric power to employ the essence of the coal instead of the coal itself. This meant a revolution in transport and a great saving. Under these circumstances the production of power became a new industry.

Mr. Pember had not concluded when the Committee adjourned till to-day (Friday).

NORTH METROPOLITAN ELECTRIC SUPPLY BILL.

On Tuesday the consideration of the proposals contained in this bill was resumed by the Committee of the House of Commons presided over by Mr. A. H. Brown.

Mr. WM. L. MADGEN, one of the promoters, said the extent of the district proposed to be served was approximately 18 square miles. On the east was the river Lea, navigable for barge traffic from London to Hertford; almost parallel with the Lea was the Great Eastern Railway, running to Hertford; the Great Northern Railway, running to Hertford via Hatfield, and other railways running through the district. He believed these facilities would attract a number of small manufacturing trades now carried on under unfavourable conditions in the east-end of London. In Germany electrical installations are being put down in some of the agricultural districts for the purpose of supplying farmers with current for agricultural purposes, and electrical ploughs are now being made in Germany for that purpose. I think the charge for electrical ploughing is from 8 marks to 10 marks per acre. Very little has been done in this country in the direction of the application of electricity to agricultural uses.

Mr. MOON: What do you say as to the distances from the proposed power station to the distributing centres?—The distances are quite practicable, and the serving of two or more distributing centres from the same trunk main is not only possible, but is very commonly done. At the present moment nearly the whole of the area, with the exception of Harrow, is absolutely barren of electrical supply; at Walthamstow, what might be termed a preliminary plant has been put in, and Hornsey, which obtained its electric lighting order two years ago, has actually invited tenders from companies willing to take over and work the order.

Do you think that the result of your obtaining the powers you seek would be that places like Harrow and Walthamstow would find it more economical to purchase electrical power from you than to go on utilising the plant they have put down?—It is, of course, quite optional for them either to continue manufacturing their own or to take a bulk supply from us or a partial supply from us.

Mr. CLAUDE BAGGALLAY Q.C. (for Edmonton District Council and other authorities): You think you would take people from existing districts where their work is to be found to new works?—No, manufacturers would come very readily, I believe.

I gather from yourself, Mr. Raworth and others, that the works are likely to be situated principally near the river Lea, so that if you have to supply remote districts in Hertfordshire or in West Middlesex the works near the Lea would have to bear the added cost of long length of main?—We propose to supply at a uniform price throughout the whole district.

But people near the Lea who want a cheap supply will have to pay something towards the cost of supplying at a uniform price the western and northern parts of the district?—No; you are quite wrong.

Lord ROBERT CECIL, Q.C.: Supposing the existing small Distribution Company establishes its generating station at Hertford, do you think they will abandon the site in the event of the bill passing?—No, they regard that as the pioneer station. They will immediately make arrangements for supplying electricity in bulk from the main generating station, and will take the smaller plant away. There is a ready market for such plant.

Mr. MOON: Supposing this bill passes, what will take place at Hertford?—The Distribution Company has certain statutory obligations, and they must commence to supply. In the event of the bill passing, the main will be immediately run along the Lea valley, through Hoddesdon and Ware, probably right into Hertford, and as soon as a bulk supply is available the generating plant at Hertford and Barnet will be shut down and taken elsewhere.

This concluded the case for the promoters.

Counsel for the opponents of the bill having addressed the Committee,

Mr. BARTLEY DENNIS asked that in the event of its being passed the Harrow Electric Light and Power Co. should be exempt from its operation.

On Wednesday the CHAIRMAN said: We find the preamble of the bill proved, but in view of the importance of the principles involved the Committee will postpone the consideration of the clauses until Thursday, June 28, in order that we may secure as much uniformity as possible with the other bills now before the Electric Power Bills Committee.

WAR OFFICE CONTRACTS.

In the proceedings, on Friday last, before the Select Committee of the House of Commons which is enquiring into certain allegations of fraud and irregularity in connection with War Office contracts during the 12 months to April last, the charges brought against the Walsall Electrical Co. were investigated. It is clear from the evidence already given before the Committee that these charges are of a nature which could be easily much exaggerated, as we know from Messrs. Stiff and Sons' letter to us (p. 233 of our issue for June 1). Mr. Jackson presided.

Mr. W. PEARSE, R.E. Inspecting Department, Woolwich, said that in January last a representative (Mr. F. Brown) of the Wallsall Co. called upon him at Woolwich Dockyard, respecting a number (8) of electrical testing instruments supplied by the company and rejected on inspection. Witness explained the defects, and showed Mr. Brown the record of tests of the instruments complained of, and also explained the department's requirements. Mr. Brown appeared to be pleased with what witness stated, and admitted the goods were rejected for sufficient reason. He then placed his hand in his pocket and asked if witness would accept a trifle for the trouble he had been put to. Witness declined. Mr. Brown then asked him for his private address, and this he also declined. Mr. Brown then went away, and witness reported the circumstances to the chief examiner, who advised him to report to the inspector, and he did so.

By Mr. SHEARMAN, counsel for the Walsall Co.: The eight small instruments were worth about 50s. a-piece.

Mr. FREDERICK BROWN, managing director of the Walsall Electrical Co, being a member of the Society of Friends, was allowed to affirm. He said he agreed with Mr. Pearse's account of what happened at the interview. When he offered Mr. Pearse a trifle for his trouble he did not know that he was the person responsible for testing the instruments. His object in asking for his private address was to send him two tickets for the theatre, as he was at the time contracting for a theatre and had some spare tickets. Mr. Pearse had been very civil and had given him all the information he required. He now realised that his action was open to misconception, but he had certainly no fraudulent intention. In reply to a statement by Mr. Major, director of Army contracts, that the work of the Walsall Co. had been generally unsatisfactory, he stated that the total value of the War Office acceptances between 1897 and 1899 was over £1,000, while the rejections represented

Digitized by Google

a value of about £100. The date when his firm's name was struck off the War Office list was stated as Jan. 17, yet they actually sent in a tender on March 23 at War Office request. Until he saw the name of his firm in the newspapers as having been taken off the list he had no idea whatever that they had been so struck off. No notification of the fact had been made to them, since they had the right of appeal in such a case, and he thought this was a great hardship.

The CHAIRMAN: As a man of business, if anyone had subjected a confidential servant of yours to this process of "treating," would you not have deemed it extremely improper?—Looking at the matter as I do now I think probably I should. In this case, however, Mr. Pearse had returned the instruments to us, whereas we are supposed to fetch them. This was extra trouble, which I thought worth acknowledging. I think Mr. Pearse acted quite rightly in refusing, and I have no complaint to make of him.

LONDON COUNTY COUNCIL TRAMWAYS.

The Select Committee of the House of Commons, presided over by Mr. W. H. Holland, on Tuesday considered the London County Tramways (No. 1) Bill promoted by the London County Council authorising the construction of 11 extensions to the Council's existing tramways north of the Thames; and on the south side the doubling of the existing line of tramway along Nine Elms-lane and the erection of a generating station at Camberwell for working by electric traction the tramways from Westminster and Blackfriars Bridge to Kennington and from Westminster to Tooting. The bill was opposed by several local authorities, the omnibus owners in London, the North Metropolitan Tramways Co., the North London Railway Co., and owners and frontagers along the routes.

Mr. DU CANE, for the promoters, said the proposed new tramways or junction lines were confined to the northern side of the Thames, the widenings were both on the south and north, and the electrical equipment was on the south. In the county of London there were 115 miles of tramways, of which the Council owned 48 miles on the north and 24½ miles on the south of the river, or 72½ miles in all. The Council's northern tramways were worked under lease by the North Metropolitan Tramways Co., which paid a dead rent to the Council, with an additional payment should the profits increase beyond a certain amount. In the south 24½ miles were worked by the Council themselves. The Council sought by this bill and another that had already passed the House to equip generally their system of tramways for electric traction. Most of the extensions had been suggested to the Council by the authorities of the districts through which the lines would run, and, with two exceptions, were unopposed. Opposition came from the Holborn District Board of Works, who objected to the proposed line along Rosebery-avenue, against the Drayton Park extension, and the line at Evering-road, Stoke Newington, on the extreme east. The bill was also opposed by the London General Omnibus Co., who claimed to represent the omnibus interest of the county of London. The other bill promoted by the Council (No. 2) was one authorising the Council to adopt electric traction subject to the approval of the Board of Trade. In the present bill, however, there were no works included which did not involve new construction. The lines of tramways proposed would run through the districts of some 15 local bodies of whom only three were opposing.

Mr. J. W. BENN, L.C.C., said the Council had found the tramways of London in a state of confusion, and were endeavouring to bring the whole system into order. In three years they would own the whole of the tramways of the metropolis. The object of the bill was to couple up the lines by filling up breaks so that passengers might travel through from point to point. By the other bill before the House it was proposed to apply electric traction to all the lines in London. If the overhead trolley system were adopted the local authorities were to be first consulted and their consent obtained. It was proposed to apply electric traction to the extensions now asked for. Any system could be employed by the Council with the approval of the Board of Trade. With regard to the North Metropolitan Tramways Co., the Council contended that the clause in their lease covering reconstruction and extension was sufficient protection for that company. If there was any doubt, provision was made in the lease for arbitration. The omnibus opposition might be summed up in the fact that they feared competition with electric traction. If the Council's No. 2 bill passed, the provisions of this bill in regard to the electrical equipment of the Tooting line would be unnecessary. This bill had provided a generating station and mains to give effect to bill No. 2. Whatever happened to No. 2 bill the Council were very desirous to electrically equip the Tooting line. Under the powers taken over by the Council from the tramway companies, they could equip certain lines experimentally; but, as the cost was £15,000 per mile, including the generating station, it was impossible to do so, subject to pulling up the system should it not be approved by the local authority. The electric car, occupying the same area as the horse car, would carry 70 passengers against 46 by the horse-driven car. The substitution of electric for horse traction would, it was calculated, save in London some 9 miles of road space, the same number of passengers being carried.

Sir ALEX. BINNIE, chief engineer to the London County Council, said the cost of the extensions included in the bill with points and crossings would be £109,400. The electric equipment of the Westminster and Tooting line would cost £186,500, and that of the Blackfriars and Kennington tramway £57,600. The total cost of the proposals of the bill would be roughly £466,000, inclusive of site for the generating station (£90,000).

Yesterday (Thursday) Prof. A. B. W. KENNEDY said that last year the London County Council had asked him to report as to the use of electric traction in London. He had examined the tramways of Europe and the United States, and made himself thoroughly acquainted with all modes of electric traction. The general conclusion of his report was that an electrical system with underground conductors was perfectly feasible in London, and would not be extravagantly expensive. Any such system could be worked with economy and success, and he was in favour of an underground system as most suitable for the centre of the metropolis. In the outlying parts it might be preferable to adopt the cheaper overhead system. A veto was given by the bill to local authorities in regard to the use of the overhead system, and with respect to any other system they would have a right to particulars and to appear before the Board of Trade. After considering this report, the Council had instructed him to prepare plans, which he was now doing. The tramways would be so laid that neither the tram rails, nor the slot rails, nor any other part of the apparatus would interfere with the ordinary traffic, and to all outward appearance the conduit system would look exactly like the Brixton cable line, which had been working for years. There were practically two systems proposed to be used—the conduit system and the surface-contact system. The conduit system was at work on a large scale in America and in Europe. Under that system the two running rails were seen, with the slot rails in the centre with an open groove, underneath which there would be a continuous conduit carrying the two steel conductors, one being the negative and the other the positive. These would be carried on insulators entirely separate from each other. From the cars would drop down a very thin plough—a framework about 15in. long and ¼in. thick connecting with the conductors and picking up the current. There was complete insulation as in the case of electric light conductors. The surface contact had not been so extensively used as the conduit system. The principle of that system was that the electricity was collected by the car from metallic discs or contact studs placed between the rails. These discs were circular, about 8in. in diameter, with a contact surface about 3in. in diameter. The intention was to set each disc in bitumen blocks about 8in. by 15in., which would be sloped to meet the pavement of which they formed a part, and would be so constructed that in the highest part the discs would be only ⅛in. above the surrounding pavement. That ⅛in. would not present a sharp edge. There would be no danger whatever to the street traffic. The system had certain advantages in regard to cost and simplicity, and the Council thought they ought to have the right to adopt it if, on use, it was found advantageous without the local authorities having an absolute veto such as had been given in respect of the overhead system. With the surface contact system the current returned through the rails, so that there were no insulated returns, and the system was similar in that respect to the overhead system. There was a conductor running underneath the studs and connected to a moveable pipe of iron There was nothing else below ground. The tramcar carried certain electromagnetic appliances, which when they came over one of the studs lifted the piece of iron and brought it in contact with th stud through which the current was carried to the motors on the car. Directly the car passed the iron pipe dropped down and was no longer in contact. The actual contact was made by means of a skate which rubbed along the top of the studs. These studs were only alive when the skate was passing over them, which was when the car was passing. Some of the existing depots would be used as transforming stations, and he thought the site at Camberwell was a good one for the generating station, being close to the London Chatham and Dover Railway, upon which coal sidings would be constructed under the powers of the bill. The station would be large enough to meet the needs of South London for many years to come, even though the whole of the tramways were operated by electricity. The electric cars proposed to be used would carry 64 people, and the speed would be regulated by the Board of Trade. The initial difference of cost between the conduit and the surface-contact systems was about £2,000 per mile. The surface-contact system in use at Paris was a defective system, being worked in a complicated and inefficient manner, and was not suitable for use in London. So far as principle was concerned it was the same as that now proposed. He did not propose the Potter system, except that that system was a surface-contact system. From Westminster Bridge to Clapham Common, and from Blackfriars Bridge to Kennington the conduit system would be used, and from Clapham Common to Tooting the surface-contact system. From the conduit system there was no danger of electrolysis being caused, because the returns were insulated. With the surface-contact system there was the same risk as with the overhead system, the returns not being insulated. The Board of Trade regulations protected anyone from injury in that respect.

The Committee then adjourned till to-day (Friday).

CROYDON TRAMWAYS AND IMPROVEMENTS BILL.

On Tuesday the omnibus bill promoted by the Croydon Corporation, dealing, among other things, with tramways, came before the section of the Police and Sanitary Committee of the House of Commons of which Lord E. Fitzmaurice is chairman. In 1894 the Corporation obtained power to construct tramways within the borough, which they leased to the Croydon Tramways Co. The Corporation are about to take over these tramways, and seek power to wind up the company and to construct further tramways, to be worked electrically on the overhead trolley system. It is also proposed to take power to supply electric energy to adjacent local authorities. For the tramways borrowing powers of £170,000, and for the generating stations £35,000, are asked. One clause in the bill enables any department of the Government to represent to the Board of Trade that the use of their electrical powers injuriously affects any instruments or apparatus, whether electrical or not, used in any observatory or laboratory, and then the Board of Trade shall, after inspection or inquiry, have power to require the Corporation to use such reasonable and proper precautions, including insulated returns, as the Board of Trade may deem necessary, to prevent such injurious affection. The bill was opposed by

Digitized by Google

two sets of petitioners—the frontagers on a part of the line and the Lambeth Water Co., who allege danger to their mains from electrolysis, and ask for a clause throwing the cost of any accidents through electrolytic action upon the Corporation.

After hearing evidence and counsel, the Committee decided against the petition of the frontagers and passed the portion of the preamble relating to the tramways.

The Committee then proceeded to deal with the opposition of the Lambeth Company.

Mr. STEPHEN SELLON (for the Corporation) said that such a provision had never been inserted in any Act of Parliament, although the Lambeth Company had unsuccessfully tried to get it inserted in another case this year. In 1893 a Joint Committee of both Houses considered, *inter alia*, this question of electrolytic action arising from electrical tramways, and their conclusion was that the only instances brought before them came from abroad, and were cases in which the tramways had not been properly constructed. Upon their report and recommendation the Board of Trade adopted a clause which was intended to secure the proper construction of electrical tramways and so to prevent the possibility of electrolytic action; and the Corporation had in this case adopted the Board of Trade standard clauses.

Mr. JAMES SWINBURNE (for the petitioners) said he had some apprehensions, even if the Board of Trade regulations were properly enforced, in the case of Croydon (where 2½ volts was the maximum pressure to be used and the area was limited), on account of the possibility of the extension of the system or of its being joined up with the County Council or some other large system in the South of London. He explained that electrolytic action was gradual, and resulted in eating away the pipes. Though the recording instruments, the use of which was insisted on by the Board of Trade, showed the difference in pressure and the amount of leakage at a station, they did not show that a portion of the leakage which left the line traversed the pipes and returned to the line.

Having heard counsel, the Committee deliberated in private, after which the CHAIRMAN, in giving their decision, said they did not see how they could grant the compensation clause asked for.

The tramway clauses were then gone through and adjusted in the usual way.

BOURNEMOUTH TRAMWAYS.

On Tuesday the Select Committee of the House of Commons, presided over by Mr. W. H. Holland, again considered the bill confirming the Tramways Provisional Order of the Bournemouth Corporation.

Mr. PEMBROKE STEPHENS, Q.C., for the Corporation, said that since their last meeting the promoters had had an opportunity to consider the position, and they found that certain points had been overlooked, and certainly some alterations would have to be made either by the Committee or in another place. Two things seemed to have been prominently in the minds of the Committee: one, the question of precedents, and the other the question of continuous working. By the action of the Corporation and the Committee tramways had been secured, and the Committee had imposed the terms that, if within two years the tramways were not constructed, other parties should be at liberty to make them. Now there came in the difficulty, which was not emphasised on the last occasion, that the two schemes were not absolutely alike. The Corporation scheme was for tramways generally throughout the whole of Bournemouth, and the scheme of the Christchurch Bill for tramways approaching Bournemouth, and with a considerable break in the middle, and if the Corporation tramways were not made in sympathy with that scheme continuous running would be impossible. The private tramway company had no continuous line to offer, and therefore the continuous line was a concession to the company, which they had no means of offering an equivalent for.

Mr. MOON, for the Christchurch Co., submitted that the Committee, having giving its decision, would not re-open the question of running powers at all.

Mr. PEMBKOKE STEPHENS: It had been put before the Committee with some confidence that there were precedents for compulsory running powers being given over corporation tramways. It was, however, a mistake to say that such powers had been given by Parliament. The Committee had therefore been unintentionally misled, and if the decision of the Committee rested on that statement it was based upon an error.

The CHAIRMAN: The Committee cannot see that any new point is now raised. The Committee decided on the evidence before it.

Mr. BALFOUR BROWNE, Q.C., for the Tramway Co., said his case had been opened on its merits. An agreement had been signed between the two agents, and the present application was bad in practice, and he protested against the matter being opened up again.

Mr. STEPHENS: If the decision of the Committee is irrevocable I shall be obliged to go to the other House and say that a thing had been done which was without precedent in giving these running powers over the Corporation tramways.

The CHAIRMAN: The Committee are advised that, as a matter of order, the bill is no longer before the Committee, so that, however disposed they might be, they have no power to re-open the matter.

Mr. BALFOUR BROWNE, Q.C., protested as strongly as he could against the action of the Corporation. The matter had been heard fully by the Committee, a decision come to, a careful agreement between parties prepared and signed by the Parliamentary agents and accepted by the Committee. The case for the running powers was not opened as one of precedent at all, and it was for Private Bill committees to make precedents. There had been no miscarriage, but if there had been it had been condoned by the agreement signed and settled.

Mr. STEPHENS said if the Committee did not feel themselves at liberty to hear the Corporation case, all he asked was that nothing should be done to hamper what was a great public case.

The CHAIRMAN: The Committee cannot see their way to re-open the matter. If anything new had occurred it can be stated in the other House. There is nothing to be added or taken away from the previous decision of the Committee.

TOTTENHAM DISTRICT COUNCIL BILL.

This bill came before a Select Committee of the House of Commons yesterday. Its objects include the proposed supply of electricity, for which borrowing powers are sought for £36,000.

Mr. R. C. GLEN explained the position of the electricity proposal, and pointed out that the only opponent was the Middlesex County Council, who would not have had a *locus standi* if the promoters had proceeded by way of provisional order. The County Council urged that they might in the future propose to run trams on the electric overhead trolley system, and the powers sought by the promoters if granted would prove detrimental to that undertaking.

The CHAIRMAN of the Tottenham District Council gave evidence of the great desire for a supply of electricity in the district, and said the estimate of Messrs. Preece and Cardew of the cost of the electric installation was £36,000.

Mr. EARLE (for the Middlesex County Council) said that although the actual duty of doing repairs and maintaining the main roads was retained or claimed by the District Council, the obligation to pay, in the name of a contribution, really the whole cost of repair and maintenance, was cast upon the County Council. So long as a private undertaker was carrying on the electric lighting work, the public were protected by the District Council, whose only interest is to protect the public, but here, although the District Council did not lose their public character, they came forward as traders, and their interest as traders might conflict to a considerable extent with their interest as a public authority. He therefore asked that the County Council should be put, in reference to main roads, in precisely the same position with regard to the scheme as the District Council would be if the work had been undertaken by a private company. There were many cases where this had been done.

The CHAIRMAN decided not to give the protection sought, and passed the preamble of the bill.

TWICKENHAM ELECTRIC LIGHTING PROVISIONAL ORDER BILL.

The right of the Middlesex County Council to be heard in opposition to the above measure was considered yesterday (Thursday) by the Court of Referees of the House of Commons, Mr. Parker Smith presiding. Mr. HARPER, for the County Council, in claiming a *locus standi*, held that his clients contributed towards the cost of the main roads which would have to be broken up under the powers of the bill, and that, therefore, they were entitled to be heard against the preamble of the measure. Mr. SHAW, on the other hand, contended that the management of roads was vested in the district council, and that it would be absurd to give two authorities the right to appear in opposition to the bill in respect of their ownership of main roads. The County County only paid a contribution towards the maintenance of the roads. Besides, this was an electric lighting order, and the eventual purchasers were the District Council and not the County Council. The *locus standi* was disallowed.

UNDERGROUND TELEGRAPH WIRES.

In the House of Commons, on Monday, Mr. HANBURY, in reply to Sir John Leng, said that the underground telegraph line from London to Birmingham met the demand for uninterrupted communication over that part of the country where destructive gales were most prevalent, but it was not at present found to be so generally useful as the overground line. The Postmaster-General could not at present contemplate its extension to the North.

MUNICIPAL, FOREIGN & GENERAL NOTES.

Ashton.—The Council have decided to apply for borrowing powers for a considerable extension of the plant at the electricity works.

Asylum Lighting.—The Fifeshire County Council has decided to obtain a report from an electrical engineer as to the cost of lighting their asylum electrically.

Beverley.—Consideration by the Council of the report of Mr. A. H. Gibbings on electric lighting has been postponed until the decision of the Parliamentary Committee on the Electric Power bills has been given.

Bermondsey (London).—The Vestry have approved drawings prepared by their consulting engineers (Messrs. Kincaid, Waller & Manville), for the refuse destructor and electricity supply buildings, and tenders are shortly to be invited.

Birmingham.—The Public Works committee have approved of the adoption of central standards with cross arms for that portion of the Bristol-road tramway route between the Suffolk-street terminus and Bromsgrove-street, and side poles with brackets for the remainder of the route.

Burton-on-Trent.—The accounts of the Gas and Electricity works were presented at the Corporation meeting last week and approved. The chairman (Councillor Lowe) said he thought the

Digitized by Google

Council would agree they had made substantial progress during the past year in their electric light undertaking, and the time was not far distant when that department would become a remunerative one. They had spent £1,825 in replacing the old rubber mains with British Insulated Wire Co.'s cables. The removal of the old mains had cost £2,359, and had been paid for out of the reserve fund of the gas works. The profit on the gas works had been increased from £6,105. 15s. in 1899, to £6,521. 7s. 3d. in 1900. Taking all things into consideration, the committee thought the gas and electric light undertakings had worked most satisfactorily. The report was agreed to. Afterwards Councillor Lowe moved that the price of gas be increased 5d. per 1,000ft. He said that either the price must be raised or they would fail to make any contribution to the rates, which would in consequence go up at the very least 6d. in the £. However much opposed to their interests, it was their duty to make the usual provisions in their accounts. The increase in their coal bill was £8,700, and the increase of 5d. per 1,000ft. would bring in about £6,250, leaving £2,500 to be met by the increased price of residuals. Councillor Hutchinson contended that the price was being raised much higher than was necessary, especially as the charge for electric current was to remain at its present figure. He considered the electric light consumer thus received an unfair preference over his neighbour who used gas. Eventually, however, the resolution was carried.

An application by the promoters of the Swadlincote and Woodville tramways for the Council's consent to the construction of tramways within the borough has been referred to a committee.

Cardiff.—The Tramways committee are about to invite tenders for about 1,000 tons of rails, fishplates, bolts, copper bonding, &c.

Carlisle.—The total receipts of the electricity department for the year ended March 25 amounted to £2,102. 11s., of which £1,592. 19s. 9d. was for current for private and £510 for public lighting. The expenses of generation were £1,169. 5s. 7d., distribution £90. 6s. 10d., public lamps £178. 11s. 10d., rents, rates and taxes, £32; management expenses £663. 8s. 6d., and insurance £30. 8s. 6d., a total of £2,164. 1s 2d. Interest came to £868. 18s. 6d. and sinking fund instalment to £1,189. 10s. 5d., leaving a net loss of £2,091. 1s. 5d.; 167,032 units of current were generated, 103,155 sold and 22,379 used on works. Private consumers took 85,922 units, and 44,233 units were used for public lighting. The total maximum supply demanded was 169 kw. The capital expenditure was £31,152. 5s. 2d., or £1,189. 5s. in excess of borrowing powers.

Chesterfield.—A canvass of ratepayers has resulted in offers to take electric current for the equivalent of 7,950 8 c.p. lamps. The canvass was made at the request of the Local Government Board.

Clacton.—At last week's meeting of the Council it was proposed to instruct the consulting engineer (Mr. W. H. Trentham) to prepare plans and specifications for an electric lighting scheme, but an amendment that the matter stand over for six months was carried.

Colne.—Application for sanction to borrow £40,000 for electric lighting has been decided upon. The Council already have one good customer, as current will be supplied to the Colne and Trawden light railway.

Coventry.—The accounts of the electricity department were presented an approved at the Corporation meeting on Tuesday. During the year ended March 31 the number of consumers increased from 135 to 236, and the revenue went up from £3,597 to £4,188. The profit had been £786, against £333 for the previous 15 months.

Crewe.—The completion of the 4,000th locomotive engine at the Crewe works of the London and North-Western Railway Co. was made the occasion of general rejoicings on Saturday, when Mr. F. W. Webb, chief mechanical engineer of the company, presided over a large gathering at the Mechanics' Institute, Crewe. A bronze medallion of the late Sir Joseph Whitworth, presented to the Institute by former Crewe students who have succeeded in securing Whitworth scholarships or exhibitions, was unveiled by Mr. Groves of the Patent Office. Mr. Webb, referring to the completion of the 4,000th engine, said although they had been hard pressed at the works to keep abreast of their business, they had not yet had to go across the Atlantic for any of their engines. He had informed the directors of his company that if any American locomotive were sent to Crewe for repairs they would have to get some one else to repair it, for he could not do so. He considered the locomotives turned out at the Crewe workshops equal to any in the world. It is not unlikely that if a similarly firm attitude had been assumed by other gentlemen in Mr. Webb's position, the importation of American locomotives into this country would have been on a much smaller scale. Mr. Webb was subsequently presented with the freedom of Crewe by the Town Council, and mentioned that when he first went to Crewe they had turned out their 250th engine and were employing 510 workmen, whereas in 1899 the employés numbered 7,428, and their engines had travelled 74,000,000 miles.

Dudley.—Until further notice electric light consumers are to have the option of being charged at a uniform rate of 5d. per unit or 6d. for two hours a day (between 5 p.m. and 7 p.m. in winter and 6 p.m. and 8 p.m. in summer) and 1½d. after. The chairman of the committee (Ald. G. H. Dunn) announced at the last meeting of the Council that the award of the Board of Trade as to the amount the British Electric Traction Co. had to pay the Corporation for electrical energy was very satisfactory. The new generating station could produce 700 kw., and there was room to lay down an engine two or three times the size of the present one, so that they would be able to meet any demand for electricity made upon the town in the future. In 1902 the Corporation would have to take over the tramways and re-lease them to the company for 21 years. If they could not agree as to conditions the Board of Trade would arbitrate. The Council have applied for sanction to borrow £10,000 for wiring consumers' premises in the district.

Dundee.—At the annual meeting of the Gas Corporation on Wednesday Treasurer Ritchie announced that the income of the electricity department for the year had been £10,755. 14s. 7d., and the surplus £628. 1s. 10d. The estimated income for the current year was £15,450. 1s. 10d., and the expenditure £14,535. The price of gas has been increased from 3s. 4d. to 3s. 10d.

Electric Driving.—In the report of the Ebbw Vale Steel, Iron and Coal Co. for the year ended March 31 it is stated the board have under consideration the remodelling of the blast furnace plant, and the extensive introduction of electric power.

Electric Launches on the Thames.—The subject of electrically-driven launches and other boats for the Thames traffic is one which is at the present moment receiving considerable attention from electrical engineers, the London County Council, and others. The Immisch Electric Launch Co. has just issued a pamphlet on this subject. These launches were introduced by Messrs. Immisch & Co. as far back as 1889, and the number of these vessels has continued to slowly but surely increase until now a considerable capital is invested in the development of this form of electrical progression. The pamphlet gives us much technical information as the public can absorb, and there is little difficulty in showing the advantages of electrical over other forms of mechanically-driven boats, from their handiness, the simplicity of the mechanism, easy working, perfect control, and the fact that the driving power is stored out of the way, leaving the whole of the room in the boats for the comfort and convenience of the passengers. The pamphlet gives particulars of up-stream and down-stream trips, the distances, the names of the up-river locks, and some interesting particulars of the chief places to be visited. A number of maps are given to aid the tourist adopting this method of visiting the charming upper reaches of the river. Last, but not least, a list of the launches available, their carrying capacity, and the charges made by the company for hiring and service. The time is surely at hand when this company will achieve a larger measure of success than it has yet attained.

Mr. W. Rowland Edwards of the Thames Valley Launch Co. writes us on the subject of electric launches and other vehicles as follows:—Motor cars can now be used comfortably between Oxford and London, the Thames Valley Co.'s charging stations being now available at the following places: Weybridge (river side), Maidenhead (Boulter's Lock), Hurley (at the lock), Pangbourne (adjoining Whitchurch Bridge), Shillingford Bridge, and by arrangement with the Oxford Electric Lighting Co. The Thames Valley Co. have a number of electrical boats available for hire and purchase.

Electric Lighting in the North Metropolitan Districts.—At the Tottenham Council last week the clerk reported that at the recent conference on the electric lighting question representatives from Friern Barnet, Edmonton, Finchley, Southgate, Wood Green, and Tottenham, agreed to ask the various authorities who had not yet done so to support the principle of co-operation in electricity supply. Edmonton, Southgate, and Tottenham had already passed resolutions to this effect.

Electric Lighting Plant for German Sea-going Vessels.—The German Bundesrath has decreed that apparatus and materials required for electric lighting on board sea-going vessels, including searchlights and their appurtenances, shall be admitted free of duty into the German Customs Union.

Electric Pumping.—At the meeting of Young's Paraffin Light and Mineral Oil Co. (Ltd.) last week, the chairman (Sir James King) said that among the items of special outlay for the current year was that for electric pumping plant at Newliston, which would accomplish the pumping much more efficiently than at present, and at greatly reduced cost.

"**Electric Shock.**"—*Inquest.*—An inquest was held last week on the body of an assistant night watchman named Golton, in the employ of the London Electric Supply Corporation, at the Deptford Works. It appeared that deceased suffered from a weak heart. His duties were to make certain rounds during the night and to enter in a log book certain particulars. It was no part of his duties to touch the machinery, except to do a little switching occasionally during the night. The evidence of Mr. Clement J. Bailey, superintending engineer at the works, went to show that deceased went to the switchboard to make an entry in the log book, which was kept near this spot. The voltage of the conductors near where deceased was

Digitized by Google

found was 2,500. Evidence was given by members of the company's staff and by medical men that death was due to asphyxia and not to electric shock. Dr. A. J. Russell, of Deptford, stated that the post-mortem examination disclosed no marks or burns, except a small bruise on the nose where deceased had fallen. Death was due to asphyxia, the cause of which he had not been able to ascertain. The appearance of the body did not, however, exclude the possibility of death from electric shock. The valves of deceased's heart were diseased and the heart's action might have failed through a fall from faintness. Dr. Lewis Jones, of the electrical department, St. Bartholomew's Hospital, said he had never known of a case of death from electric shock where the voltage was 2,500 without a burn, which was usually a distinguishing mark of death by electricity. He was of opinion that deceased could not have come in contact with the conductor near which he was found without receiving a burn. Mr. G. W. Partridge, chief engineer to the Corporation, said the fuses found near deceased were not in use. The jury with one dissentient returned a verdict of death from asphyxia caused by electric shock. The dissenting juryman said he did not consider the evidence sufficient to justify the verdict.

Electric Tramways in London.—Some members of the London County Council recently had an interview with the President of the Local Government Board (Mr. Chaplin) and the President of the Board of Trade (Mr. Ritchie) on matters relating to the government of the metropolis, when a request was made that increased facilities might be provided, by legislation or otherwise, for the construction of electric tramways in districts where the Council had powers to build artisans' dwellings. The President of the Local Government Board had no difficulty in meeting the views of the deputation, and the President of the Board of Trade expressed the opinion that the wishes of the Council would best be attained by altering the Standing Order which rendered the consent of the local authority an essential preliminary to the use of thoroughfares.

Electricity in Mining.—On Wednesday the bottom of the shaft in No. 2 mine of Bridgewater Colliery, Walkden, belonging to the Bridgewater trustees, was lighted electrically for the first time. The electric light, which supersedes oil lamps at the bottom of the shaft, also extends nearly 200 yards in a tunnel leading to the workings.

Engineering Amalgamations.—Negotiations are practically completed for the amalgamation of Sir Christopher Furness, Westgarth & Co. (Ltd.), marine engine builders, Middlesbrough, with Messrs. T. Richardson & Sons, electrical and mechanical engineers, Hartlepool, and the newly-acquired Scotia Engine Works, Sunderland.

The firm and business of R. Napier & Sons, Govan (builders of a large number of vessels engaged in cable laying and repairing work) is to be absorbed in Messrs. Wm. Beardmore & Co., Parkhead, Glasgow. The latter firm is building considerable extensions to its establishment at Parkhead.

Engineering Trade Dispute.—It is announced that the A.S.E. officials have decided that their members shall cease to work overtime after 25th inst. "until some method of settling the wages question has been agreed upon." The engineering employers of the North-East Coast have declined to submit demands of the men for an increase of wages to arbitration.

French Submarine Cable Enterprise.—M. Ordinaire on Monday submitted to the French Chamber of Deputies (on behalf of the Colonial committee) a report on the bill before the Chamber for colonial submarine cables. *The Times* states that the report approves the proposed cable from Oran to Tangier, which would dispense with the use of the English or Spanish cables, but condemns the proposed extensions of that cable to Marseilles and Teneriffe, advocating a direct line from Brest to Saint Louis as less expensive and as being easily connected with a Central America and a Congo cable. The report advocates the connection of Madagascar with the Congo by submarine and inland telegraphs and with Tongking *via* Réunion. The report, without definitely pronouncing, is in favour of the laying and working of these cables by private companies, the State not possessing sufficient apparatus for constructing them and being unlikely to work them with success commercially.

Glasgow.—The Corporation on Wednesday agreed to increase the salaries of Mr. W. W. Lackie and Mr. J. C. A. Ward, assistant engineers of the electricity department, as mentioned in our last issue.

Greenock.—Additional plant, estimated to cost about £8,000, is to be erected at the electricity works in order to provide current for the projected electric tramway.

Halesworth (Suffolk).—The Colchester Brewing Co., who are putting down electric lighting plant, have offered to supply tradesmen in the district with current. The Council have, however, appointed a committee to consider and report upon the advisability of themselves applying for electric lighting powers.

Hampstead (London).—The profit on the working of the electricity department for the year ended March 25 amounted to £8,265. The Finance committee has transferred £5,061 out of the profits to the reserve fund, and £10,000 to be invested in London County 2½ per cent. consolidated stock, making the total amount invested £16,221, representing 10 per cent. of the capital expenditure. The sum of £3,205, the balance of the net profit for the year, is to be set aside to form the first instalment towards a depreciation fund for meters and plant.

Hanley.—The total receipts of the electricity department for the year ended March 31 were £8,809. 7s. 4d., and expenditure £7,631. 19s. 7d., leaving a balance of £1,177. 7s. 9d. Interest (£2,130. 18s. 5d.) and sinking fund (£1,315. 11s. 8d.) come to £3,416. 10s. 1d., leaving £2,269. 2s. 2d. to be provided out of the general district rate fund. 537,893 units of current were sold (123,070 for public and 414,823 for private lighting), and 14,199 units were used on the works. There are 65 arcs and 80 incandescent lamps, representing a total equivalent of 35,160 30-watt lamps connected for street lighting. The total maximum demand was 550 kw.

Hastings.—A report presented by the Lighting committee to the Council meeting on Friday, recommending that several additional thoroughfares be lighted electrically, and that the gas company be informed that the gas lamps would not be required after Dec. 25, was adopted, and a tender for lamp pillars accepted.

Heywood.—Last week the Town Council decided to apply for a loan of £15,000 for electricity supply.

Hotel Lighting.—The Coast Development Co. are putting down a complete electrical installation for lighting their new hotel and pier at Southwold. Edmundson's Electricity Corporation have obtained the contract, which is to be carried out to the specification of Mr. A. A. Campbell Swinton.

Hyde.—The Council have appointed six representatives of the Corporation to act on the joint committee (of 24 members) of the Councils of Hyde, Stalybridge, Dukinfield, and Mossley, for promoting a joint electric lighting and traction scheme for the districts. It has been resolved to make application, in conjunction with the Dukinfield Town Council, to the Light Railway Commissioners for an order authorising the Councils to undertake the construction and working, or to contract for the construction and working of light railways in Hyde and Dukinfield. Mr. Tinker, chairman of the Electricity committee, said it was important that they should pass the resolution unanimously, as if they failed to oppose successfully the application of the Oldham, Ashton, and Hyde Electric Tramway for an extension order it would be a very serious matter to the ratepayers of the borough. He was certain, and the Electricity committee agreed, that an electric lighting station would be much more profitable and much earlier remunerative if combined with an electric traction scheme. The resolution was carried unanimously.

Ipswich.—Prof. Kennedy's electric lighting scheme has been approved by the Council, and the Electric Lighting committee has been instructed to have the specifications prepared for inviting tenders. The scheme provides for 85 public arc lamps. The joint Electric Lighting and Parliamentary Bill committee recommended that it was desirable that all the electrical work relating both to tramways and lighting should be carried out simultaneously, and in order, if possible, to avoid interference with each street more than once, that specifications should be obtained for the whole of the work required for both. The committee also recommended that Prof. Kennedy should prepare the necessary specifications for both lighting and tramways as authorised in the Council's Parliamentary bill. The report was adopted.

King's Lynn.—An inquiry has been held into the application of the Council to borrow £10,000 for electric lighting extensions. Mr. J. W. Woolstencroft, town clerk, said there was an equivalent of 1,188 8 c.p. lamps connected in excess of the total capacity of the existing plant. Mr. J. Pilling, resident engineer, gave technical details, and said the proposed extensions would allow of 9,200 additional 8 c.p. lamps being connected. The new plant would consist of two steam dynamos, one of 200 kw. and one of 120 kw., with Lancashire boilers and Belliss engines. Mr. G. Humphreys Davies appeared in opposition, and asked that the proposed increased expenditure should be delayed for twelve months. He said the local gas company were willing to erect and maintain incandescent gaslights for street lighting at £3. 7s. 6d. per lamp per annum, and if this offer were accepted the existing electric lighting plant would be available for private consumers, for which it was quite adequate.

Lathom and Burscough.—The committee have received reports on electric and gas lighting, but no decision has been come to pending the result of the Lancashire Electric Power Bill now before Parliament. The cost of electric lighting plant has been put at £7,500 and the annual working expenses at £800. The Ormskirk Gas Co. offer to supply gas at 3s. 5d. per 1,000.

Leamington.—Mr. Horace Boot, of Tunbridge Wells, has been engaged by the Council, at a fee of 50 guineas and travelling expenses, to make a valuation of the undertaking of the Midland Electric Light and Power Co., whose application for a provisional order is unopposed.

Digitized by Google

Light Railways.—An inquiry was held last week by the Earl of Jersey and Col. Boughey into the Warrington and Northwich light railway scheme. The eastern branch only was proceeded with, but, though the scheme was strongly supported by the local authorities interested, and by traders and residents along the route, it was dismissed because no compulsory powers had been obtained to acquire land. It is the intention of the engineer (Mr. R. H. Scotter) to amend this point, and again present the scheme. The western branch stands adjourned, as the time for lodging objections had not elapsed before the date of the inquiry.

An inquiry was held at Preston, on Friday, by the Light Railway Commissioners into the application of the Blackpool and Garstang Electric Light Railway Co. to construct a light (electric) railway from Blackpool to Garstang. For the promoters, Mr. Balfour Browne, Q.C., said the proposed railway would be divided into four sections. All the public authorities except Blackpool were in favour of the line. The estimated cost of the railway was £167,000, and of the electrical equipment under £75,000. After hearing local evidence, Mr. J. J. Myers, resident engineer of the line, gave evidence of the great tramway traffic on the various lines in Blackpool, and said that in 1898 the Corporation tramways carried 2,881,000 passengers, and last year 3,400,000. 2,500,000 people were carried by the Blackpool and Fleetwood Company, and about 1,000,000 by the St. Annes and Lytham trams. The necessity for a light railway was generally admitted. They would have one bridge over the proposed railway, one over the canal, and one under the public road. No. 1 railway would be 13 miles, No. 2 1 mile 5 fur., No. 3 1 fur., and No. 4 4 fur. The estimates of the cost were: No. 1, £131,816; No. 2, £23,900; No. 3, £3,647. 4s.; and No. 4, £16,147, in each case not including the electrical equipment. They expected to carry 600,000 people a year at 9d. a passenger, making £22,000, and estimated £11,250 from carriage of produce, making £33,700. Interest at 5 per cent. and cost of work would come to about £32,334, leaving £1,416 surplus profit. Mr. T. G. Lumb, C.E., also gave evidence. Afterwards evidence on behalf of Blackpool Corporation, who opposed, was taken, but eventually the Earl of Jersey said that the Commissioners believed a case had been made out, and that there was a demand in the district for a light railway, but they were not prepared to pass No. 2, but were prepared to sanction No. 1.

The Board of Trade have, after modification, confirmed the Bexhill and St. Leonards Light Railway Order (1900).

London, Walthamstow and Epping Forest Railway Act.—In the House of Commons, on Thursday last week, the President of the Board of Trade (Mr. Ritchie) said, in reply to Mr. S. Woods, that he had received from the agents for the promoters of this line, a statement of reasons for delay. On May 25 the House agreed to a resolution reported from the Standing Orders Committee that leave should be given for the introduction of a bill to abandon the undertaking. He was informed that the abandonment bill would accordingly be introduced forthwith.

Long Eaton.—The Council has adjourned the consideration of the proposal to establish electricity works in the district.

Melbourne (Australia).—The profit on the municipal electricity works from February, 1899, to February, 1900, amounted to nearly £5,000. Gross revenue totalled £29,849. 13s. 2d., and working expenses £17,818. 5s. 8d., leaving a gross profit of £12,031. 7s. 6d., an increase of £2,536. 14s. 1d. on the previous year. Interest on capital (4 per cent. on £112,402. 13s. 5d.) amounted to £4,496. 2s. 2d. and sinking fund to £3,372. 1s. 7d., leaving a net balance of £4,068. 2s. 3d. A statement appended by Mr. A. J. Arnot, city electrical engineer, shows that 834 electric street lamps are in use in the city, and that 1,688,626 units of current were sold.

Montrose.—The plans of the proposed electricity works of the Angus Electric Light Co. (Ltd.) have been passed by the burgh commissioners.

Morecambe.—The gross profit on the working of the electricity department for the year ended March 31 was £1,764, against £775 last year. The total capital expenditure is £39,700. Receipts from the sale of current amounted to £3,900, compared with £1,800 last year.

Municipal Telephony.—At the meeting of the Brighton Corporation yesterday (Thursday) the Telephone Committee presented a report in which they recommended the Corporation to apply for a licence to establish a municipal telephone system for the Brighton district. So far back as April 5, 1898, application was made to the Postmaster-General for a licence, but consideration of the matter was deferred pending the report of the Select Telephone Committee of the two Houses of Parliament. Since the issue of that report, licences to establish exchanges had been granted to the municipalities of Glasgow and Tunbridge Wells. On August 14 last, a letter from the Postmaster-General inquired whether, in view of the provisions of the Telegraph Act, 1899, the Brighton Council desired to renew their application for a licence, but to this communication no reply has yet been furnished. With a view to obtaining the best information on the subject of a municipal exchange, the committee had consulted Mr. A. R. Bennett.

In a lengthy report to the committee Mr. Bennett states that the existence of the independent borough of Hove complicated the working of the area by the Brighton Corporation, but telephonically considered, the two towns were practically one, and could only be worked separately at greatly increased cost and the sacrifice of efficiency. Mr. Bennett therefore treats them as one for engineering purposes. In order to obtain a licence for the area, the Brighton Corporation would have to produce to the Postmaster-General resolutions by the Hove Council and the Councils of the other local authorities within the area formally approving of the application. It was extremely difficult and even impossible to estimate the cost of constructing and working a telephone exchange in any area without an accurate knowledge of the number and location of the subscribers who had to be dealt with. The best that could be done was to assume a reasonable number and take it for granted that the location would not differ widely from that of subscribers to the existing telephone system. The present system of the National Telephone Co. comprised some 1,100 subscribers, and bearing in mind the tendency of telephone systems to expand under almost any conditions, and especially under the influence of reduced rates, he had prepared estimates for an exchange of 1,240 completed and 300 partially completed lines (corresponding in size to the existing system, and a second for an exchange of 2,080 completed and 600 partially completed lines for the guidance of the committee. He was of opinion that it was the larger of the two estimates which should be considered. With 2,000 subscribers Brighton would still be far behind many Continental cities in respect to the number of telephones to population, and would have fewer than the island of Guernsey, where there was one telephone line to every 60 inhabitants. As to capital expenditure, Mr. Bennett considered that, bearing especially in mind the increased cost of material, £18. 10s. per line would be sufficient provision for the cost of a first-class metallic-circuit telephone exchange system within the Brighton area, constructed in accordance with the specification annexed by the Post Office to licences to local authorities. If advantage were taken of the proximate opening of the streets for tramways to lay telephone conduits in the same trenches, a saving could be effected in this figure. The spare, partially completed lines would cost £8 each as a maximum. This worked out as follows:—1,200 line exchange: 1,200 subscribers and 40 public telephone lines complete at £18. 10s., £22,940; 300 partially completed lines at £8, £2,400; total, £25,340. 2,000 line exchange: 2,000 subscribers and 80 public telephone lines complete at £18. 10s., £38,480; 600 partially completed lines at £8, £4,800; total, £43,280. In the larger system the cost of the outside work would be somewhat reduced owing to the greater number of lines that could be put in position at the same time, but that of the inside work would be increased in about a corresponding degree, so that the cost per line would not be altered. The plan of construction would be, in the central districts, underground lines as far as circumstances would permit, with overhead lines in the more distant parts and suburbs. An average receipt per working line of about £5. 5s. per annum would be required to place the exchange on a remunerative basis at first. The Corporation was bound to offer subscribers the option of paying under the toll system, if desired, instead of an inclusive annual rental. Experience showed that the gross annual payments of toll subscribers did not, as a rule, amount to so much as £5. 5s. It was incumbent, therefore, in order to maintain the requisite average, to charge more for the inclusive service than would otherwise have been necessary. Mr. Bennett suggested the following tariffs as likely to result in an average receipt of not less than £5. 5s. per annuum. Should a considerable majority, as seemed not unlikely in such a busy town as Brighton, prefer unlimited service, that tariff could be reduced below £5. 10s. after a short experience. In Glasgow only 10 per cent. of the Corporation subscribers were taking the £3. 10s. and 1d. per call system. If that proportion held for Brighton the following tariffs would produce an average receipt of £5. 8s. 4d. per line per annum, allowing only one 1d. call per working day to each toll subscriber, which was more than was required to make the exchange pay its way. £5. 10s. for the unlimited rate might thereafter prove unnecessarily high:—Tariff No. 1: £5. 10s. per annum (payable in advance) to cover an unlimited number of calls. Tariff No. 2: £3. 10s. per annum (payable in advance) and a toll of 1d. per call (payable quarterly or half-yearly). 480 penny calls (about 1½d. per working day) would be required to overtake the unlimited rate, and so this tariff would be very appropriate for small users. The rates to cover installation, maintenance and Government royalty, and to apply over the whole of the Brighton area. The Swiss plan of a decreasing rental, say £5. 10s. for the first, £5. 7s. 6d. or the second, and £5. 5s. for the third and succeeding years, might be conceded to those willing to sign agreements for five years. On the 1,200-line exchange, he estimated the revenue at £6,787 per annum; and on the 2,000-line exchange at £11,469. After deducting working expenses (£6,441. 3s. 10d.) from the estimated revenue on the 1,200-line exchange, the net revenue was given at £315. 16s. 2d. The working expenses on the 2,000-line exchange were put at £10,269, and, deducting this from the estimated revenue, £1,200 was left as net revenue. Not only was provision made in these estimates for recovering the whole capital in 25 years, but for renewing the whole of the plant, so that at the termination of the licence the Corporation would be in possession of an efficient up-to-date system which would have cost them nothing. If this provision be deemed excessive, then the amount saved from the depreciation and renewal fund would be available towards a further reduction of rates. In the competition the National Telephone Co. would be at an enormous disadvantage in not possessing underground wayleaves, and would have to rely upon their old overhead single-wire system against the modern metallic circuit system of the Corporation. The company was much embarrassed in Brighton for want of wayleaves, and could not face the

Digitized by Google

problem of converting their system to metallic circuit overhead. For the same reason the company would not be likely to reduce rates. They would not be able to find room overhead for the additional wires which such a proceeding would bring them. In numerous towns the company had accepted underground wayleave agreements which contained a clause binding the company to give the town granting the wayleave the benefit of any reductions in charges which might thereafter be made in any other town of corresponding size. The existence of the agreements constituted an important safeguard for corporations against unfair competition.

The committee thought the amount of certain items of expenditure was insufficient in view of local circumstances, but Mr. Bennett replied that on the fullest reconsideration he was convinced that his estimate was substantially correct, and required no amendment, except such as might be rendered desirable by the operation of local circumstances with which he was not familiar. The committee also considered a letter from the National Company requesting the Council to re-open the question of granting them permission to lay wires underground. Mr. W. E. L. Gaine, the general manager of the company, attended the committee meeting on May 22, but, after careful consideration of the suggestions made on behalf of the National Company, the committee came to the conclusion that the proposals submitted were not sufficiently advantageous to render it advisable that the Corporation should grant the company the right of laying wires under the streets. On the general question of the advisability of instituting a municipal telephone service in Brighton, the committee thought it desirable that such a scheme should be established, and that the Brighton telephone exchange area should include, not only Brighton and Hove, but the whole of the area between Rottingdean on the east and Shoreham on the west, and extending north as far as Burgess Hill. It was mentioned that the Act of Parliament did not make provision for the conduct of a telephone exchange jointly by two or more local authorities, and if it were desired to establish an exchange system under joint management a special Act of Parliament would be required. The committee accordingly recommended that application be made to the Postmaster-General for a licence to establish and carry on a system of public telephonic communication in the Brighton area for 25 years, the maximum rates of charge for exchange subscribers to be as follow: For unlimited service, £7; limited service, £3. 10s. and toll of 1d. per call, and that the Councils of the several districts included within the proposed exchange area be requested to give their consent to the application.

The Council yesterday adopted the Committee's report.

Newport (Mon.).—The accounts of the electricity department for the year ended March 31 were presented and discussed at the meeting of the Corporation last week. The chairman of the electricity committee (Councillor G. H. Llewellyn) stated that the gross profit amounted to £4,092, and provision had been made for all loans sanctioned, except the new loans. He hoped the small profit made (£403) was a beginning of better times. Several member supported a suggestion that the opportunity afforded by the gas company, who had raised their rates by 17 per cent., should be taken the greatest advantage of, and that at the earliest opportunity the price of electric current should be reduced from 6d. to 4d. per unit. The report of the Lighting and Tariff committee as to the erection of a power station and the electrical equipment of the Corporation-road tramways caused a rather animated discussion. The point at issue was as to whether the Electricity committee should act jointly with the Lighting committee. The report was adopted.

Personal.—Among the passengers by the Windsor train which was in the smash at Slough station of the Great Western Railway Co. on Saturday was Mr. R. G. Rawkins, secretary of the Notting Hill Electric Light Co. Mr. Rawkins lives at Slough, and the carriage in which he travelled was fully occupied by eight passengers. Hearing the cries of persons on the platform who saw a collision was inevitable, Mr. Rawkins and six of the other persons in the carriage jumped out on to the platform, leaving one passenger only in the carriage who was immediately afterwards killed, the carriage being completely splintered. We congratulate Mr. Rawkins upon his escape.

Portsmouth.—The accounts of the electricity department for the year ended March 31, now issued, are not quite so satisfactory as those of last year. This is attributed by Mr. E. Price, the superintendent of the station, to two causes—increased expenditure for coal and decrease in the current sold per lamp connected. During the year 426 new customers, representing the equivalent of 7,090 8 c.p. lamps, were connected, against 413 customers and 7,282 lamps in the previous year. 1,393,091 units of current were sold, including 972,051 for private lighting. The total receipts amounted to £23,991. 0s. 10d., and the income from private lighting alone was £18,177, against £14,696 last year. The capital expenditure has been increased to £161,056 from £140,776, and now represents £122 per kilowatt demanded against £124 last year.

Presentation.—Mr. J. J. England, who is entering the service of the British Electric Traction Co., was entertained on Friday last by the staff of the Cork Electric Tramway Co. at a farewell concert, and at the close was the recipient of a presentation.

Price of Gas in London.—Gas consumers for light, power, and domestic uses in the extensive area served by the Gas Light and Coke Co. north of the Thames received a severe shock this week in the form of an official intimation that "from the date of recording meter indices for the June quarter the price of gas is to be 3s. 5d. per 1,000 cubic ft.," vice 3s. deceased. The Gas Light and Coke Co. has an evil reputation for doing nothing by halves. This time they have been very thorough, as apart from the serious rise in the price of the commodity they have to sell, the day for taking the meter indices appears to have been brought forward. When will Parliament, or whatever public body should take the matter in hand, devote some little time and attention to the woes of the gas consumer within the area of the Gas Light and Coke Co. north of the Thames. We hear and see a good deal of competition in electricity supply. If the days of the gas fiend were not already numbered, the opprobrium now centreing upon everything connected with gas supply in the metropolis should prove the last nail in its coffin.

Royal Agricultural Show, York.—At the Royal Agricultural Society's Show at York, during the week, a cleverly constructed automatic electrical horse feeder has been exhibited, manufactured by Thomas Wood, Mills and Co., of Bristol. The hopper is filled with the allotted ration for the horse and an electrically operated clock is set at a fixed hour and as the alarm strikes the hopper is liberated and the ration of corn is shot into the manger. Another arrangement of this device is provided with a button, which can be pressed by any person in attendance on the stables, and a ration of food for the occupants of the stalls can be regularly and automatically provided.

St. Pancras (London).—The Electricity committee have considered the question of introducing "free" wiring for intending customers of the electricity department, but decided that the Vestry have no powers to embark in the business. Mr. Smith (chairman of the committee) hopes that, on the Vestry becoming a borough council in November, authority will be obtained to carry the system into effect.

Salford.—At a special meeting of the Council on Wednesday a report of the Selection committee in regard to the reconstruction of the Electric Light committee was discussed. The Mayor (Alderman Rudman) said that the Selection committee had done its work with care, and he asked members to assist the new committee in carrying out its duties during the next four months. He moved the election of the following members: Aldermen Holland, W. Robinson, and Shaw; Councillors Barrett, Bates, Broxap, Higson, Hodgson, Huddart, Leach, Mather, Muir, Stephens, Wilkinson, Worsley, and Yearnshaw. Only two of these members were on the old committee. The report was adopted and the members named duly appointed.

Sanding Tramway Tracks.—The action brought by the Dublin Corporation against the Dublin United Tramways Co. for the defendants to show cause why they should not be compelled to sand the tramway tracks under their control (which has been fully reported in *The Electrician*) came again before the Queen's Bench Division, Dublin, last week, and the magistrate's decision, ordering the company to sand the tracks, was upheld by a majority.

Shanklin.—An electric lighting scheme has been submitted by Edmundson's Electricity Corporation and will be considered by the Council in committee. The company offer to supply current to lamps of 30 c.p. each at £2. 10s. per lamp per annum, and if the contract is for seven years to fit the lamps free of charge. An alternative scheme was to erect 10 arc lamps of 750 c.p. each at £12 per annum each, and 149 incandescents at £2. 10s., making a total of £492. The present cost of lighting is £507 per annum.

Shoreditch (London).—Mr. H. E. Kershaw has severed his connection with the Lighting committee. Mr. N. Moss, chairman of the committee, has also resigned, and Mr. H. E. Winkler has been elected to the chairmanship. The Vestry has sanctioned an expenditure of £3,250 for laying ducts and cables from Reeve's-place sub-station to Great Cambridge street, and an outlay of £350 for a subway for mains between Coronet-street and Pitfield-street.

Silvertown and its Neighbourhood.—If there is one spot on the earth's surface which is well known to electrical men the world over, either from actual acquaintance or by repute, it is Silvertown and the near neighbourhood. Silvertown is named after the factories erected by Mr. Silver about 40 years ago, and which are now in the occupation of the successor to Mr. Silver's company, the India Rubber, Gutta Percha and Telegraph Works Co. (Ltd.). The district within easy reach of Silvertown is also the locale of the factories of Messrs. W. T. Henley's Works Co., and those of Messrs. Siemens Bros. & Co., the Telegraph Construction and Maintenance Co., Messrs. Johnson & Phillips, the Western Electric Co., and many other prominent manufacturing firms in the electrical industry. It will be news, however, to most that the district has an interesting history, that in the near neighbourhood is situated quite a large number of historical landmarks; but that this is so is shown by an instructive little work, just published, from the pen of Mr. Archer P. Crouch, who, by means

Digitized by Google

of nearly 100 pages of text and a number of excellent illustrations, gives a complete history of the district in an attractive form. The publisher is Mr. Thomas Burleigh, 17, Cecil-court, Charing Cross-road, London, W.C., and the published price is only 1s. The book will well repay perusal. Several excellent photo illustrations of the c.s. "Silvertown" are given, as well as cable-laying incidents associated with this vessel and the c.s. "Buccaneer."

Southport.—Last week a proposal to light London, Chapel and Eastbank-streets by arc lamps was considered by the General Purposes committee. An amendment in favour of incandescent gas was moved by the chairman of the gas committee (Dr. Isherwood), and after an exciting debate the voting resulted in a tie. The mayor (Ald. Griffiths) gave a casting vote in favour of the amendment, but on a protest from the advocates of electric lighting he did not press the amendment as a substantive motion, and the matter will have to be thrashed out later. The delay is interfering with the work of the Tramways committee, who wish to push on with the preliminary work in connection with the conversion of the lines, but cannot order poles until they know whether or not the streets named are to be illuminated by electricity.

Telephone Junction Line Working.—A new rule of the Postmaster-General is to the effect that inattention at the National Telephone Co.'s exchanges, where it can be proved to be due to the fault of the company's operators and not to the existence of a fault on the wires, is in future to be treated as though it were inattention on the part of the company's subscribers, and trunk calls which fail from the former cause are to be charged for.

Tynemouth.—Mr. Charles Turnbull, borough electrical engineer, has issued a useful pamphlet entitled "Notes on Electricity, for Light and Power," which will be of service to those contemplating putting in electrical installations for lighting or other domestic purposes. Tynemouth Corporation has arranged for a system of "free" wiring, to be undertaken by the Northern Electrical Engineering Co. (Ltd.).

West Ham.—The Lighting and Tramways Committee have submitted a report for the past half-year, which states that the gross profit was £2,002. 8s. 10d., and the net profit £470. 4s. 11d., which they recommend should be transferred to the general district rate in part payment of £1,380, the total loss charged to that account. After the whole of that deficiency has been repaid steps are to be taken to create a reserve fund sufficient to meet the cost of renewals. The committee suggested that £172, cost of wiring artizans' dwellings, be charged against the housing scheme. The consulting engineer (Mr. John J. Steinitz) states that, in comparison with the average of five London municipal concerns, West Ham sold about half the number of units, and the total cost was only 0·09d. higher. That was a satisfactory result, especially when its was remembered that the coal account was exceedingly high, and was being compared with the coal account of the five stations before the immense increase in price took place. The average price obtained for current for private lighting in West Ham was 4·32d., compared with 4·77d., the average of the other five stations, and West Ham was selling current about a halfpenny a unit less than the average of the other local authorities who had electricity works in London. The return for public lighting showed a still greater difference, as West Ham obtains 1·9d. as against an average of 3·6d., or rather more than 1½d. less than the average. It was, said Mr. Steinitz, only their electrical engineer's (Mr. J. K. Bock) careful management that enabled such satisfactory results to be obtained.

Workhouse Lighting.—An increase of 7d. a thousand in the price of gas has induced the Penistone Guardians to appoint a committee to report upon the lighting arrangements. Probably electric lighting will be substituted.

The South Shields Guardians have received the sanction of the Local Government Board to adopt electric lighting at their workhouse. Tenders are being invited.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

TENDERS INVITED.

Extension of Time.—The date for tenders for the overhead equipment for about 16 miles of equivalent single track of tramways, for the Corporation of *Durban*, Natal, South Africa, has been extended. Tenders (in duplicate) to Messrs. Webster, Steel and Co., 5, East India-avenue, Leadenhall-street, London, E.C., by July 20, or to town clerk, Durban, by mail delivery, on or about Monday, Aug. 13.

Swansea Corporation require tenders for main switchboard and instruments and a battery of accumulators and accessories. Specification may be obtained at the Guildhall, Swansea, and can be inspected (but not obtained) at the offices of the consulting engineers (Messrs. Kincaid, Waller & Manville), 29, St. George-street, Westminster. An advertisement gives further particulars, and tenders must be forwarded to Messrs. Kincaid, Waller & Manville before noon of July 5.

Salford Corporation require tenders for overhead equipment for tramways, exclusive of steel poles. An advertisement contains additional particulars, and specification may be obtained at the offices of the consulting engineers (Messrs. Lacey, Clirehugh, & Sillar), 2, Queen Anne's-gate, London, S.W., and 78, King-street, Manchester. Tenders to town clerk (Mr. L. C. Evans), Town Hall, Salford, by 10 a.m. of July 16.

Limerick Corporation require tenders for the supply, delivery, and erection of electrical plant and apparatus, particulars of which are set out in an advertisement. Specification, &c., may be obtained at the office of the consulting engineer (Mr. James Enright), 47, Victoria-street, London, S.W., and tenders must be sent to the town clerk (Mr. Wm. N. Nolan) by July 14.

Edinburgh Corporation invite tenders for the supply of copper strip. An advertisement contains further particulars, and specification, &c., may be obtained at the offices of the resident electrical engineer (Mr. F. A. Newington), Dewar-place. Tenders to town clerk (Mr. Thomas Hunter, W.S.), City Chambers, by July 9.

Tunbridge Wells Corporation being about to establish a municipal telephonic system, invite tenders for instruments, apparatus, material, and accessories, particulars of which are set out in an advertisement. Copies of the specification can be obtained from the telephone engineer (Mr. A. R. Bennett), Castle Chambers, West Regent-street, Glasgow, and tenders have to be delivered to the offices of Mr. W. C. Crippe, town clerk, Town Hall, Tunbridge Wells, not later than Thursday, July 5.

Croydon Corporation invite tenders for the re-construction of the present tramway track and the construction of new tramways and paving of roads. Specification, &c., can be obtained at the offices of the town clerk, Town Hall, Croydon, after June 25, and all further particulars can be had from the engineer (Mr. E. W. Monkhouse), 14, Old Queen-street, Westminster, S.W. Tenders must be sent to Mr. E. Mawdsley, town clerk, Town Hall, Croydon, by 12 noon of July 10.

Blackpool Corporation invite tenders for trolley poles, cables, and trolley wire, boosters, and switchboards and a storage battery. Further particulars are given in an advertisement, and specifications may be obtained from the borough electrical and tramway engineer (Mr. Robert C. Quin). Tenders to chairman of Electric Lighting and Tramways committee by 10 a.m. July 23.

Aron Electricity Meter (*Ltd.*), 46, Upper Thames-street, London, E.C., require tenders for the supply and delivery of large and small metal cases. Further particulars are set out in an advertisement, and tenders must be delivered to the company by noon of July 2.

Warrington Corporation invite tenders for the installation of the electric light in the town hall, bank house, museum, school of art, drill hall and gymnasium. Specification can be obtained from Mr. W. H. Grimsdale, Bank House. See advertisement.

Tenders are required for an electric lighting installation (generating plant, wiring, &c.) for the Union workhouse, Hanton, *South Shields*. Tenders by 26th inst.

Glasgow Corporation invite tenders for work, in connection with alterations and foundations for machinery at sub-stations at Coplaw, Dalhousie, Partick and Kelvinhaugh. Tenders by 29th inst.

Leeds Tramways committee require tenders for ironwork in connection with the raising and extension of the Hunslet car sheds. Tenders by 25th inst.

Dudley Corporation invite tenders for condensers, pumps, cooling tower, &c. Tenders to town clerk (Mr. H. C. Brettell) before 30th inst.

Newcastle-upon-Tyne New Tramways committee require tenders for trolley wires and attachments. Tenders to town clerk (Mr. Hill Motum) by 25th inst.

Manchester Tramways committee invite tenders for the overhead equipment of three tramway routes. Tenders (addressed to chairman) by 30th inst.

London County Council require tenders for the supply (within three months of order) of about 70 arc lamp standards for lighting Victoria Embankment. Tenders to clerk (Mr. C. J. Stewart) by July 10.

Trimdon (Co. Durham) Parish Council invite tenders for public lighting by electricity or acetylene gas. Tenders by July 17.

Hackney (London) Electric Light committee require tenders for 220 arc lamp pillars. Tenders to clerk by July 11.

Tottenham Council invite tenders for fire alarm posts and instruments and about 11,000ft. of ¾in. gas barrel. Tenders to clerk by July 3.

Alford District Council require tenders for lighting from August 14, 1900, to May 14, 1901.

Harrow District Council require tenders for public lighting for one year. Tenders to engineer by 26th inst.

Digitized by Google

French Post and Telegraph authorities invite tenders until July 5 for 12 tons of galvanised iron wire (1mm. diameter) and 135 tons ditto (4mm. diameter). Tenders to Le Sous Secretariat d'Etat des Postes et des Telegraphes, 103, Rue de Grenelle, Paris.

Belgian State Railway authorities invite tenders for supply and erection of plant and apparatus for the electric lighting of the railway stations and workshops at Montigny, Couillet and Chatelineau. Tenders to La Bourse, Brussels.

The Municipal Authorities of *Cassano al Jonio* (Italy) invite tenders until July 21 for electric lighting for 25 years.

TENDERS RECEIVED AND ACCEPTED.

In our issue of June 1 we gave a list of the tenders accepted for the supply of electric lighting extension plant at Melbourne. In a report on the tenders prepared by the municipal electrical engineer (Mr. A. J. Arnot), and by the consulting engineer (Major P. Cardew, of Messrs. Preece and Cardew), the tender of the Allgemeine Elektricitäts Gesellschaft was recommended for acceptance. The Council, however, decided to accept the tenders indicated below :—

Contract No. 1.—(Boilers and Economisers).

		Time for delivery.
Babcock & Wilcox (*accepted*)	£6,604	20 weeks.
Davey, Paxman & Co.	13,102	55 „
Sterling Boiler Co.	8,310	30 „
Danks & Co.	6,500	—
Rowland & Co.	6,100	—

Contract No. 2.—(Engines, Dynamos, Equaliser, Booster, and Switchboards).

Thomas Parker (Ltd.) (*accepted*)	£22,367	12-14 months.
(Ditto)	23,081	12-14 „
(Ditto)	22,926	12 „
Allgemeine Elektricitäts Gesellschaft...	24,463	10 „
(Ditto)	22,363	11½ „
(Ditto)	17,574	10 „
(Ditto)	27,480	10 „
Johnson & Phillips	20,000	22 „
Australian General Electric Co.	20,276	9 „
(Ditto)	22,502	9 „
Siemens Bros. & Co.	22,090	15 „
Brush Co.	23,215	18 „
Mather & Platt	24,926	10½ „
(Ditto)	24,833	10½ „
(Ditto)	24,276	10½ „
(Ditto)	23,290	12½ „
Easton, Anderson & Goolden	27,419	19 „
Greenwood & Batley	24,953	17 „
British Thomson-Houston Co.	24,811	14½ „
(Ditto)	24,706	14½ „

In the accepted tender for engines and dynamos, Thomas Parker, Ltd. specified for Belliss high-speed compound engines. The dynamos are for an output of 350 kw. at 460-520 volts. To the amount of the tender (£22,367) will have to be added customs duty, which will increase the total by £6,000. The Tudor accumulators will have a capacity of 1,000 ampere-hours and the B. I. W. cables will be paper insulated and lead covered.

The following tenders have been received by the Newington (London) Vestry for the supply and laying of insulated electric mains, conduits, junction boxes, &c., in the side streets :—

W. T. Henley's Telegraph Works Co....	£10,137 12 1	British Ins. Wire Co.	£9,026 5 6
Western Electric Co.	9,952 15 0	Callender's Co.	8,992 10 4
Siemens Bros & Co.	9,063 8 4	W. T. Glover & Co.	8,870 6 0
		St. Helens Cable Co.	8,464 0 0

The tenders have been referred to the consulting engineers (Messrs. Kincaid, Waller & Manville) for report, and the Vestry will be invited to accept a tender at their meeting on July 4.

The King's Lynn Town Council has accepted the following tenders :—

Laurence, Scott & Co., two steam dynamos and one small motor generator	£3,498 10
Yates & Thom., boiler, economiser, condenser, pump, &c.	2,375 0
Lewis, Bayliss & Co., extensions to switchboard	206 0
Callender's Company, feeder mains, joint boxes and dynamo cables	523 5

The following tenders, received by the Bermondsey (London) Vestry for the supply and laying of electric light cables, conduits, and junction boxes, have been referred to the Electric Lighting committee for consideration :—

British Ins. Wire Co.	£8,643 15 10	Siemens Bros. & Co.	£8,113 9 11
Western Electric Co.	8,219 0 0	St. Helens Cable Co.	8,109 16 8
Callender's Co.	8,212 7 1	W. T. Glover & Co.	8,018 4 8

As stated in our issue for June 8th, the Paddington (London) Vestry have accepted the tenders of Mr. A. C. Harnden for alterations and additional work in connection with the electric lighting arrangements at the public baths, for the total sum of £153. Eleven tenders were sent in ranging from £153 to £795 (!). One item in the tenders was for extras if steel tubing was used throughout the alterations in place of wood casing. The tenders for this work ranged from £2 to £250 (!) the lowest being from the Concentric & General Contract Co. and the highest from Messrs. J. R. Reedman & Co. The accepted tender for this portion amounted to £10.

St. Pancras (London) Vestry received eight tenders for the supply of coal to the generating stations, prices showing a considerable advance over those of existing contracts. It was decided to accept the tender of Messrs. Facer & Co, for Warwickshire coal, at £1. 2s. 1d. for the Stanhope-street station, and £1. 1s. for the King's-road station, and for Nottinghamshire coal at £1. 2s. 11d. and £1. 2s. 4d. The tender of Messrs. Rickett, Cockerell & Co. for Nixon's navigation steam coal, at £1. 9s. 10d. per ton, compared with £1. 1s. 9d. under expiring contract. The higher price, the chairman (Dr. Smith) stated, would increase the cost of generation by about ⅛d. per unit.

Glasgow Corporation on Tuesday accepted the following tenders for the supply of electricity meters : Messrs. Chamberlain & Hookham for 150 25-ampere, 55 50-ampere, and 75 100-ampere meters ; British Electric Meter Co. for 50 2½-ampere and 50 5-ampere meters ; and S. Z. de Ferranti (Ltd.) for 350 5-ampere, 400 10-ampere, 150 25-ampere, 55 50-ampere, 75 100-ampere, and 10 200 ampere meters.

Glasgow Tramways committee recommend the acceptance of the tender of Messrs. Thomson & Sons to erect the brickwork for the Pinkston power station at £61,000.

Only one tender has been received for the public lighting of Larne—that of the Larne Electric Light Works (Ltd.), which tendered for the evening lighting (Aug. 1 to April 30) at £482. 16s., and for the day lighting (from Oct. 15 to Feb. 15) at £43. 4s., total £526. The tender has been referred to the lighting committee for report.

Hampstead (London) Vestry have accepted the tender of Messrs. Troy & Co. for the electric lighting of the new buildings at the electricity works at £214. Five tenders were received, Messrs. Troy's being the lowest.

Hastings Corporation has accepted the tender of Messrs. McDowall, Steven & Co. for the supply and erection of 50 cast-iron lamp pillars for electric lighting at £2,205.

In September last the municipality of Porto Alegre (Brazil) invited tenders for a concession for the electric lighting of the town. We learn that no offers were received for the concession.

APPOINTMENTS VACANT AND FILLED.

Derby Technical Educational committee require lecturers and demonstrators in mechanical engineering, and in physics and electrical engineering for their municipal technical college. An advertisement gives further information, and applications must be sent to the principal by July 9.

Norwich Technical Instruction committee require an assistant lecturer and demonstrator in physics and electrical engineering. Applications to the principal (Mr. Wm. Gannon, M.A.) by July 6. See advertisement.

Eccles Corporation require a consulting electrical engineer in connection with the proposal to adapt the local tramways for electric traction to be worked by the Salford Corporation in conjunction with the Salford tramway system. An advertisement contains further particulars, and applications must be delivered to the town clerk (Mr. Wm. H. Hickson), Town Hall, Eccles, by 10 a.m. 29th inst.

The Vestry of St. John, Hampstead (London) require an assistant electrical engineer. Further particulars are given in an advertisement, and applications must be sent to the vestry clerk (Mr. Arthur P. Johnson), Vestry Hall, Hampstead, London, N.W., by July 2.

Sunderland Corporation require a chief engineering assistant, a junior assistant, and two thoroughly trained motor-men for their electric tramways. Applications to borough electrical and tramways engineer (Mr. John F. C. Snell) by 28th inst. See advertisement.

An outside superintendent is required for the Sheffield Corporation tramways department. Applications to the engineer and manager (Mr. A. L. C. Fell), Town Hall, Sheffield. See advertisement.

Reading Electric Supply Co. require a station assistant. Applications to the managing engineer (Mr. Arthur T. Cooper), electricity works, Vastern-road, Reading, by 26th inst. See advertisement.

The Council of the King's College, London, invite applications for the post of demonstrator in electrical engineering. Conditions

Digitized by Google

of the appointment can be obtained of the Secretary, and applications must be in by 30th inst. See advertisement.

Messrs. Chamberlain and Hookham (Ltd.), Solar Works, Birmingham, have a vacancy for an assistant in their experimental department. See advertisement.

The post of senior demonstrator in electrical engineering and applied physics at the City and Guilds Technical College, Finsbury, will be vacant at the close of the present session. Salary is £150, rising to £200. Applications to principal of college, Leonard-street, Finsbury, London, E.C., by June 29.

Birmingham Corporation require two lecturers for the electrical and engineering departments of the municipal technical school in September next. Applications to Mr. Geo. Mellor, Suffolk-street, by 30th inst.

Carlisle Corporation require a clerk and switchboard attendant for their electric lighting department. Further particulars are set out in advertisements, and applications must reach the city electrical engineer (Mr. Charles D. Burnet), James-street, Carlisle, by Monday the 25th inst.

A chief assistant electrician is wanted for cable works near London. ee advertisement.

An assistant superintendent is required in the Indian Government Telegraph Department. Applications to Secretary, Public Works Department, India Office, London, S.W., by June 30.

An engineering assistant for electric tramways is required by Ayr Corporation. Applications to town surveyor by 30th inst.

Mr. Arthur Ellis, of Bolton, has been appointed electric tramway engineer by the Cardiff Tramways committee. Mr. Ellis, who served his apprenticeship with Messrs. C. A. Parsons & Co., was, in 1892, appointed resident engineer to the Cambridge Electric Supply Co. In Oct., 1893, he rejoined the staff of Messrs. Parsons & Co., and in 1894 was appointed borough electrical engineer at Southport. In 1896 he was appointed to Bolton, in succession to Mr. J. H. Rider, now of Plymouth, and in 1899 became general manager of both the lighting and tramway departments of the borough.

Mr. A. B. Farrell has been appointed engineer-in-charge, and Mr. A. J. Beckett junior tester, at the Belfast Corporation electricity works.

Mr. H. Davidson, of the Leith Corporation electricity works, has been appointed shift engineer at the Blackburn Corporation electric light and tramway generating station.

Mr. A. W. Money, who has been for the past five years superintendent of the electricity department at the Earl's Court Exhibitions, has been appointed resident engineer of the Chiswick station (now in course of erection) of the Aberystwyth and Chiswick Electricity Supply Corporation.

Brighton Corporation has appointed Mr. Thomas B. Holliday electric tramway engineer at a salary of £600 per annum.

BUSINESS NOTICES.

Messrs. Evershed and Vignoles (Ltd.), of Woodfield Works, Harrow-road, London, W., have opened City offices at 110, Cannon-street, E.C, where they are represented by Mr. P. F. Brittain. All particulars regarding Evershed instruments, together with catalogues, prices, and estimates, can be obtained at the City office.

The British Electric Works Co. (Ltd.) have opened a Manchester branch at 37, Piccadilly, which will be under the charge of Mr. John Walton, for several years inspector of installations with the Manchester Corporation electricity supply department.

Messrs. F. H. Medhurst and A. Kitchin, consulting engineers, 13, Victoria-street, London, S.W., have dissolved partnership. Debts by Mr. Medhurst.

The telephone number of Mr. A. P. Lundberg, Pioneer Electrical Works, 477 to 487, Liverpool-road, London, N., is 154 King's Cross.

BANKRUPTCIES, LIQUIDATIONS, &c.

The discharge of John E. Evered, 12, Miller-street, Camden Town, N.W., has been suspended for four years from the conclusion of the public examination in July, 1899. Bankrupt failed in June, 1899, with liabilities £7,905, assets to be realised £10. 16s. 7d. He formerly acted as commercial agent, and subsequently factory superintendent to the Electrical Undertakings Co. (Ltd.).

Claims against the Lithanode Electric Storage Co. (Ltd.) (in liquidation), must be sent by July 19 to Mr. Stuttaford, 11, St. Helen's-place, London, E.C., solicitor to the joint liquidators (J. M. Richardson and H. F. Pollock).

Winding-up Petitions.—A petition was presented in the Manx Chancery Court, on Monday, by Mr. Robert Okell, a creditor, for the winding-up of the Isle of Man Tramways and Electric Power Co. (Ltd.), and for the appointment of Mr. W. H. Walker as liquidator. Several shareholders opposed, and the hearing of the petition was adjourned till yesterday (Thursday).

A petition for the winding up of the Westminster Automatic Telephone Syndicate, Ltd., will be heard in the High Court on 26th inst.

A petition for the winding up of the Gutta-Percha Corporation (Ltd.) will be heard in the High Court on 26th inst.

Plant for Sale.—The St. Helens Electric Supply and Tramways committee invite tenders for the purchase of plant at their Warrington-road works. Particulars of the plant, which is in first-class condition and can be inspected on application to the engineer (Mr. J. S. Highfield), Corporation electric power station, Cropper's hill, St Helens, are set out in an advertisment.

In our advertisement columns Messrs. Wheatley Kirk, Price and Co. announce the sale by auction, at the Grays Engineering Works, Grays, Essex, on Tuesday, Wednesday and Thursday, July 3, 4, and 5, at 10 for 11 a.m. prompt, the contents of the works, including a variety of tools, machinery, utensils, stores, &c. The whole may be viewed on Monday, July 2 and on the mornings of sale. Catalogues (6d. each) may be obtained on application at the works, of Messrs. Hatten and Asplin, solicitors, Bank Buildings, Grays, Essex, or of the auctioneers, 49, Queen Victoria-street, London, E.C., and Albert-square, Manchester.

Exhibition.—The International Tramways and Light Railways Exhibition to be held at the Agricultural Hall, London, N., will open on Saturday, 23rd inst., and remain open to Wednesday, July 4, from 10 a.m. to 10 p.m. There are over 100 exhibits, including the latest appliances for the complete equipment of electric tramways.

Asbestos Goods.—Cresswell's Asbestos Co. (Ltd.) have ready a series of well-arranged catalogues of asbestos goods, manufactured at the company's works at Wellington Mills, Bradford, Yorks. A large variety of goods are listed.

Patent Amendment.—Mr. Robert Lundell, 527, W. 34th-street, New York, has applied for leave to amend specification of Letters Patent No. 7,978 (1899) for "Improvements in and relating to electric motors or dynamo electric machines." Particulars of the proposed amendment are given in the *Illustrated Official Journal* (Patents) of the 13th inst, and notices of opposition must be given within one month of that date.

"Invicta" Accumulators—Messrs. Ashmore, Benson, Pease & Co., of Stockton-on-Tees, and 181, Queen Victoria-street, London, E.C., have issued a price list of "Invicta" accumulators, which can be obtained by the trade on application. The company will shortly be in a position to supply "Invicta" traction accumulators, as used in a number of motor vehicle competitions with, it is stated, considerable success.

"Hart" Cells.—The Edison & Swan Co., who have already the sole agency for the "Hart" accumulator cells for Glasgow and Dublin, have made similar arrangements for Belfast and Cork.

Electricite & Hydraulique Plant.—This company, for which Messrs. Witting Bros. (Ltd.), 49, Cannon-street, London, E.C., are agents, have now ready an instructive brochure describing and illustrating the works and track of the Ixelles-Boendael (Belgium) line of tramways, constructed and equipped by the company in 1896-97.

Milling Machinery.—Messrs. Schischkar & Co., of Stafford-street, Birmingham, are introducing the "Milwaukee" milling machinery designed for the greatest possible range with the least possible overhang of parts. The column of the machine is cast in one piece, and the feed of the table is automatic in either direction through 28in, is thrown in or reversed by the same handle on the front of the machine, and can be tipped either automatically or by hand as easily under full cut as when running light. There are 12 changes of feed, varying from 0·006in. to 0·130in. per rev. of spindle. The net weight is 2,300lb.

Watches for our Naval Heroes.—Messrs. S. Smith & Sons, Ltd., 9, Strand, London, have recently executed an order for a large number of keyless watches for presentation to each of the officers and men of H.M.S. "Powerful," on the occasion of their being paid off after their return from an active participation in the hostilities in South Africa. The watches are full hunters, the cases of plain silver, close fitting so as to be damp proof. The front cover is engraved with the name of the recipient and his rating on board ship. The watch movement has a special escapement to withstand vibration and change of temperature, and instead of steel, gold hands have been used to obviate damage from damp. The presentation was made by the mayor of Portsmouth.

Westinghouse Plant.—A pamphlet describing combined tramway braking and heating apparatus manufactured by the Westinghouse Co. is just issued. The chief advantages claimed for this apparatus are: economy and certainty of operation, accessibility of all parts, simplicity of construction and operation, automatic control and the electrical heating of the cars without cost for current.

Manganese.—Buyers of manganese ore are notified by Messrs. Kittel and Co. (Ltd.), 5, Fenchurch-street, London, E.C., that owing to the increase in railway rates in the neighbourhood of the company's mines, the price of manganese ore has been raised.

Digitized by Google

Insurance of Electrical Plant.—The Law Accident Insurance Society (Ltd.) have added a branch for the insurance of all descriptions of electrical plant against breakdown, including periodical inspection. The proposed insurance will include protection against legal liability for personal injuries or damage to property up to an agreed amount.

Agents Wanted.—Agents are wanted in the principal towns for the sale of "Stellite" electrical fittings. Applications to the secretary, British Electric Works, (Ltd.), Cheston-road, Aston, Birmigham.

Exports of Electrical Apparatus and Material.—The following list gives official particulars of the exports of British manufactured electrical apparatus and material (including telegraph and telephone wire and material, but not including electrical instruments or machines, which are not separately specified) from June 13 to June 19, with the ports of destination :—

Aden, £46. *Africa*—Alexandria, £116 ; Algoa Bay, £66 ; Cape Town, £144 ; Durban, £180 ; East London, £101 ; Port Said, £55. *Argentina*—Buenos Ayres, £2,121. *Australasia*—Adelaide, £25 ; Brisbane, £307 ; Sydney, £1,250 ; Townsville, £1,186 ; Wellington, £208. *Azores*, £129. *Belgium*—Antwerp, £22 ; Brussels, £31. *Canada*—Montreal, £70. *Ceylon*—Colombo, £830. *China*—Shanghai, £129 (telegraph material). *Denmark*—Copenhagen £137 (telegraph cable). *France*—Boulogne, £20 ; Paris, £100 ; Rouen, £70. *Germany*—Hamburg, £1,200 (telegraph material). *Holland*—Amsterdam, £63. *Hong Kong*, £540. *India*—Bombay, £306 ; Calcutta, £584 ; Madras, £18. *Japan*—Tokyo, £41 ; Yokohama, £941 ; Yokosuka, £578. *Malta*, £35. *Mauritius*, £146. *Portugal*—Lisbon, £27. *Russia*—Archangel, £103 ; St. Petersburg, £80 (telegraph material). *Straits Settlements*—Penang, £150 ; Singapore, £323 (including £66 telegraph material). *Sweden*—Stockholm, £482 (telegraph material). *West Indies*—Kingston, £32. Total £12,993, against £20,346 in the corresponding week last year (June 14 to 20).

PATENT RECORD.

The following list of Applications for Patents and Specifications published has been compiled for this journal by Messrs. J. C. Chapman and Co, *Chartered Patent Agents, of 70, Chancery-lane, W.C., from whom any available information in connection with Patents, Designs, and Trade Marks may be obtained.*

SPECIFICATIONS PUBLISHED.

Note.—All Specifications can now be obtained at the uniform price of 8d. each.

1899.

4,727. Taylor. Electric conductor conduits and turn-outs for tramway and railway propulsion.
4,931A. Wise (Crehore and Squier). Telegraphy. (Date claimed under Patents, Rule 19, March 6, 1899.)
6,812. Bacon. Magnetic power transmitting devices.
6,933. Casella. Step-by-step printing telegraph instruments.
6,993. Schloesser and Moeres. Switching contrivances for two electric incandescent lamps connected up together.
7,105. Orling and Brannerhjelm. Apparatus for controlling the reversing mechanism for rudders or the like by means of electrical waves. (Date applied for under International Convention, February 27, 1899.)
7,577. Ballance and Jefferson. Method and apparatus for operating contacts for electric traction.
7,761. Gardner. Telegraphic transmitting instruments.
7,863. Cazin. Electric incandescent lamps and their manufacture.
8,075. Carter. Electrical double pole-fused lamp post (or bracket) watertight switch to prevent fusing of main fuses.
8,223. Fraser and Elphinstone. Apparatus for testing electric primers, batteries, and cells.
8,505. Dudgeon. (von Kodolitsch) Portable electric rivetting machine.
8,672. Lewis. Electric motor carriages or vehicles.
8,975. Schloesser and Moeres. Safeguard against screw loosening on electric incandescent lamp shade holders.
9,272. Greville-Williams. Telegraphing graphic or other matter automatically without wires, and apparatus therefor.
9,367. Lehmann. Process for the production of accumulator plates.
9,691. Belfield. (Stillwell.) Electric circuit breakers.
10,246. Ericsson. Portable telephones.
10,336. Belfield. (Davis, Wright and Wurts.) Controllers for electric motors.
10,393. Campiche. Electro-mechanical impulse devices, applicable to clocks and for other purposes.
10,608. Morrison. Manufacture of conduits for electrical conductors and other purposes and apparatus therefor.
10,860. Andreas. Electric railways and tramways worked on a mixed power system.
11,189. Wise. (Actien Gesellschaft Elektricitätswerke vorm. O. L. Kummer & Co.) Dynamo electric machines.
11,227. Hall and Robertson. Ventilation of electro-motors, dynamos and the like.
11,418. Pomeroy. Electric arc lamps.
11,445. Davis. Electric circuit breakers. (Date applied for under International Convention, November 4, 1898.)
11,446. Scott. Systems of electrical distribution. (Date applied for under International Convention, November 4, 1898.)
11,456. Mills. (Bonnet, Paufique and Limière). Contact boxes for electric tramways and the like.
11,513. Bretschneider and Lauth. Self-acting mule with electrical driving gear.
11,657. Leitner. Apparatus for forming plates of secondary batteries.
11,780. Gent and Jevons. Mould for casting plates or grids for secondary batteries.
12,114. Scott. Electrically-driven fans.
12,478. Behrend. Electrical accumulators or secondary batteries.
12,787. Thompson. (Rolfe Electric Co.) Devices for breaking electric circuits and protecting the same from excessive currents.
12,956. Compagnie Electro-Métallurgique des Procédés Gin et Leleux. Electric furnaces. (Date applied for under International Convention, Jan. 27, 1899).
13,088. Mills (Bonnet, Paufique and Limière). Electric tramways or railways on a road-contact system.
13,991. Thompson. (Cantons) Monophase electric motors.
16,040. Smith and Corrie. Electric fuses and electric detonator fuses.
17,624. Mosca and Sivitz. Engine room order telegraphs and tell-tales.
21,355. Aron and Aron Electricity Meter (Ltd.). Apparatus for measuring multiphase electric currents.
22,028. Eycken, Leroy, and Moritz. Electrodes for electrolysers. (Date applied for under International Convention, May 23, 1899.)
23,663. Burke. Armature for alternating-current motors.
23,738. British Thomson-Houston Co. (Ltd.). (Steinmetz). Regulating electric alternators,
25,164. Schmidt. Electric igniting devices for lighting gas and like lamps.
25,451. British Thomson-Houston Co. (Ltd.). (Oxley.) Electric switches.
25,452. British Thomson-Houston Co. (Ltd.). (Ekstrom.) Means for cooling electric and other brakes.
25,453. British Thomson-Houston Co. (Ltd.). (Davis.) Alternating electric-current motor systems.
25,691. Feeny. (Allgemeine Electricitäts Gesellschaft.) Electro dynamo meters.
25,745. British Thomson-Houston Co. (Ltd.). (Steinmetz.) Method of regulating dynamo-electric machines.
25,748. British Thomson-Houston Co. (Ltd.). (Armstrong.) Electric railway systems worked with alternating currents.
25,752. British Thomson-Houston Co. (Ltd.). (Haskins.) Electric meters.

1900.

683. Feeny. (Allgemeine Electricitäts Gesellschaft.) Alternating current meter for small non-inductive loads.
688. Myers. Sound transmitters and disseminators for phonographs.
813. Stanecki. Manufacture of electric accumulator plates.
1,560. Lambert. Record cylinders for phonographs and method of producing the same. (Date applied for under International Convention, August 14, 1899.)

COMPANIES' MEETINGS AND REPORTS.

British Electric Traction Co. (Ltd.).

The fourth ordinary general meeting of this company was held on Monday, Sir Charles Rivers Wilson, G.C.M.G., C.B., in the chair.

The SECRETARY (Mr. George Stevens) read the notice calling the meeting.

The CHAIRMAN said : Gentlemen, the period embraced by the report and accounts covers 15 months, from Jan. 1, 1899, to March 31, 1900. The working of these 15 months has been of a very satisfactory character. We must consider that the electric traction industry has now established a firm hold upon the country, and I think I may justly say that our company may be looked upon as the leading representative of that industry. The net profits for the 15 months, after paying all general expenses and interest on debentures, amount to £130,174, including the balance of £35,451 brought forward, but not premiums on new issues of shares and debentures, which amount to £160,529, which has been carried direct to reserve. The actual profit on the 15 months' operations, excluding balance brought forward, is, therefore, £94,723, comparing with £57,974 in the preceding 12 months. There is a surplus of £130,174 to deal with, and we recommend that this should be applied as set out in the report. The amount of £5,000 now put to reduction of goodwill leaves only £5,000 to be written off, which I hope we shall do next year. The addition of £20,000 to reserve brings this up to £20,655. A big business, such as that we are conducting, obviously requires some provision being made against contingencies of all kinds or unexpected reverses. It is very desirable that in a large industry like ours, which is not altogether free from uncertainties, ample provision should be made against losses of an abnormal kind. We hope, therefore, to establish a reserve out of profits, and this reserve will be specially available in case of necessity for the equalisation of dividends. I do not wish to be misunderstood on this point, and I hope the shareholders will not interpret my words to mean that the reserve which is built up from premiums on new capital cannot be so applied ; but I am expressing the views of the Board—and I hope the feelings of the shareholders—when I say that the portion of the reserve which is made up by premiums should be appropriated to making good losses of an exceptional character. If I can make myself understood in two words it is this—that we propose a double reserve—a reserve, first of all, that may be called a capital reserve for the purposes indicated, and, secondly, a smaller reserve derived from surplus profits, entirely to be applied to the equalisation of dividends. By a policy of that sort we shall tend very much to maintain and enhance the credit of the company.

Digitized by Google

A SHAREHOLDER: You will ear-mark the premiums?

The CHAIRMAN: The premiums, as a matter of course, will go to reserve, and, as I have already said, will be used for very exceptional circumstances. Other items written off include £469 from furniture account, now standing at £2,345, and 10 per cent. will be written off this account annually in future. £23,051 has to be appropriated to the payment of the cumulative dividend on the preference shares in respect of these share for the 15 months. As to the dividend on the ordinary shares, the company was formed in October, 1896, and has, therefore, been in operation rather over three years. For the first year (to December, 1897) no dividend was paid. To December, 1898, 6 per cent. was paid, and £35,451 carried forward. We think, therefore, that if for the past 15 months we recommend the payment of a dividend at the rate of 8 per cent. per annum, and carry forward £43,783, we shall be meeting all reasonable expectations of the shareholders, and at the same time shall not do anything to weaken the financial stability of the company.

On capital account, during the 15 months we have issued 55,000 new shares, representing £550,000 of nominal capital, and also £250,000 of debenture stock. That makes altogether £800,000 of new capital. All this new capital has produced premiums of £160,529 net—after deducting all expenses and charges in connection with the issues. At the last general meeting the nominal capital of the company was increased from £600,000 to £1,200,000—and this carried with it the power to issue debenture stock up to the amount not exceeding one-half the subscribed capital. The present subscribed share capital is £950,000, leaving £250,000 unissued in 15,000 ordinary and 10,000 preference shares, and there is a balance of debenture stock which can be issued, the present issued amount being £350,000. The directors propose to allot the remainder of the share capital—the 15,000 ordinary and 10,000 preference shares—to the shareholders *pro ratâ* forthwith. We shall thus be able to satisfy the wish of the shareholders expressed at the last meeting to reserve this issue exclusively to them. The 15,000 ordinary shares will be allotted to the present holders of ordinary shares in the proportion of one new share for every three old shares, and the 10,000 preference shares in the ratio of one new preference share for every five old shares. The price of issue of the ordinary shares is £13, and the preference shares £11. The new ordinary shares will rank for dividend with the existing shares as from April 1 last, although the new shares will not be fully paid up for a few months. The preference shares will receive the preferential dividend of 6 per cent. on the amount paid up on August 15 next and from that date will rank equally as for dividend with the old shares. The bonus which the shareholders thus receive is about equal to the dividend which is about to be declared; it is really about double the dividend that you will receive. The magnitude of the company's operations will call—and at an early date—for further increases of capital, and therefore the directors recommend that the present opportunity should be taken to increase the nominal capital of the company by the creation of 80,000 new shares, half ordinary and half preference, making the total capital £2,000,000—£1,000,000 ordinary and £1,000,000 preference. There will, of course, be a corollary power to issue a proportionate amount of debenture stock.

On the question of contracts and undertakings, in the balance sheet made up to December, 1898, this item stood at £157,730; it now stands at £543,246, and represents the total expenditure on lands and buildings, permanent ways, electrical equipments, rolling stock, Parliamentary and other rights, general stores, surveys, negotiations and so forth (but not the shares and debentures in other companies). This company undertakes various operations and works on behalf of others—the promotion and surveys for new acts of Parliament and provisional orders and other powers. We do that work at a profit. Then, when powers have been obtained, we undertake on behalf of others the engineering work of reconstructing the permanent way and of installing electrical apparatus, and this also yields us a profit, and the amount expended on such works, still in progress, is £277,148. Another portion is in respect of works and undertakings which we ourselves own, lease or control. Of course, on this expenditure no profit is made until the works or undertakings are completed, and either paid for by others or operated by us for the sake of the revenue to be derived from such operations. This item represents £234,019, and includes a fairly large amount for general stores. We have for some time past recognised the need for purchasing materials in bulk and we have found it very advantageous. Latterly prices of materials have gone up enormously, but owing to the foresight of our staff we were able to make many of our purchases a long way in advance at a time when prices were much lower. We have found, and our various associated companies have found, very great convenience in having an available stock of materials to draw from, and the board have therefore decided to erect buildings for the convenient storage of tramway materials, to be afterwards retailed to our various undertakings all over the country. With this view, we have quite recently acquired a freehold site in the Midlands, conveniently situated in regard to railway facilities for the centralisation and distribution of materials. We believe that this will be a source of further economy and of profit in the future. The last item under the head of contracts and undertakings represents £32,077. This expenditure is made up of the cost of the negotiations and surveys, and legal, engineering, and other services in connection with the development and promotion of new schemes and powers, including the costs of such schemes as Barnsley, Birkdale, Blyth, Durham, Kingston, Morley, Peterborough, Sheerness, Jarrow, Spen Valley, Accrington, Cambridge, Leamington, Wellingborough, Windermere, and others. The amount may appear large, but the number of schemes it comprises is also very large, and I can speak with confidence when I say that the promotion of our schemes is carried out at the lowest cost consistent with the efficient way in which the work is done and, of course, all this work is done with a view to profit in the future.

The system of accounts which we have adopted since the beginning of the company, and which the auditors have approved, is that of allocating or charging every month the whole of our expenses to the various undertakings and schemes in regard to which the expenses have been incurred—that is, we have a separate account for every scheme, and the general expenses of the company are apportioned as near as it is practicable to each scheme, according to the cost of the time which the officers spend upon each scheme. It is a highly satisfactory and an extremely scientific method of accounts. At the end of the year all the schemes which possess vitality and constitute assets are included under the head of contracts and undertakings in the balance-sheet, and all the schemes which have proved unsuccessful or which represent losses are written off and charged to profit and loss account. The amount so written off this year is £15,185. The amount, therefore, which stands against contracts and undertakings represents valuable assets which are or will become sources of important profits; and as all items which, so far as we can judge, are not of this nature are eliminated and charged to profit and loss, I am warranted in saying that the amount standing against contracts and undertakings in the balance-sheet is not only thoroughly sound, but also a very moderate figure.

As to our investments, these stand at £950,280, and include upwards of £93,000 in Consols, National War loan at cost, and cash, exclusive of cash in hand. £60,023 represents loans and advances to associated companies and others. This amount stands to-day at about £23,000, and is perfectly good. Then there is £75,611 invested in mortgages and debenture stocks of associated and other companies. These are sound investments, and such as might almost be classed with trustees securities, though they yield a much larger return of interest. We have therefore altogether about £230,000 in valuable and realisable securities. Our reserve fund now amounts to £209,665, and the board consider it is best to leave a substantial portion of the reserve in the business of the company as we have done. The item of "shares of associated and other companies," stands at £721,180. This includes the nominal value of the shares held by this company in the original pioneer company, which is only a book entry, as we owe £25,000 to the pioneer company in respect of the purchase of that undertaking. The reasons for the continued existence of the pioneer company have nearly exhausted themselves, and there is every probability that that company will shortly be wound up. With regard to the remainder of the shares held by this company in other companies, and costing close upon £700,000, they represent a much larger nominal amount, as we have not paid par for all these shares. This £700,000 represent a nominal value of about £900,000. We think the principle of bringing these shares into account at cost is the only right one. We make a point of explaining that the profit of £123,000 on those shares stated in the accounts is subject to the shares which have been received in part payment realising par value; but after all, the total number of shares which have been received in part payment, and which have been taken at par value, is not large, and the fact must not be overlooked that many of the investments by us in shares of other companies are worth on the market very much more than the price we have paid for them. Our investment of about £100,000 in the ordinary shares of the Potteries Company appear in our books at about par, but the market price is even now much higher than the cost to us. The shares in the Oldham and Ashton Company stand in our books at about £10, and are worth in the market something between £15 and £16. The ordinary shares in the Kidderminster Company, all of which we hold, we should not dream of selling at par, which is the cost to us. The same applies to our interests in the Cork Company, in the Electrical Power Distribution Co., and other companies. Our investments comprise upwards of 60 undertakings, and £5,000 to £10,000 would amply cover any depreciation on any of these shares, without taking into account the considerable appreciation of many of them.

The proposed establishment of a superannuation fund for the company's growing staff was then referred to, and on the subject of the administration of the associated companies the chairman said: On appointing our officers and directors to act as administrators in these companies we do not allow them to take for their own use any fees or remuneration paid for their services. Whatever fees are received are paid into the treasury of this company. This principle has been strictly adhered to, and, for example, our managing director, who acts as chairman or director of something like 30 of these companies, does so without any additional remuneration by reason of holding those positions. The whole of these companies are controlled from here. The appendix to the report, you will see, enumerates 57 companies and undertakings—53 of these are tramway and light railway undertakings, but some of these will also probably undertake the supply of electric light and power. Then there are one omnibus company, one electric launch company, and one company which has recently been formed for the purpose of developing lands in the vicinity of our tramway undertakings; and there is also the Electrical Power Distribution Co., in which we have a large interest, and which undertakes the supply of power and light, more particularly in districts where we control tramway or light railway undertakings. Of the 53 tramways and light railway undertakings, 31 are actually in operation and are all working at a profit. Six undertakings are in course of construction, and 15 have only quite lately been sanctioned or are in various stages of being granted. The 31 undertakings in operation comprise 200 miles of lines, of which about 59½ are at present worked by steam, about 73½ are worked by horses, and about 62½ miles are worked by electricity, while about 19 miles are in course of being converted from steam or horse working to overhead electric traction; and a further 19½ miles of extensions connected with these 31 undertakings have been authorised. The six undertakings which are in course of being constructed measure just over 30 miles, and the 15 new undertakings which have been authorised, or which are in course of being authorised, measure about 104 miles, so that the company is interested in or controls altogether about 350 miles of tramways and light railways. Since the last annual meeting the Hartlepool tramways, the Potteries electric tramways and light railways, the Oldham, Ashton and Hyde electric tramways, the Dudley, Stourbridge and District tramways, and the tramways at Nelson, British Columbia,

Digitized by Google

have been opened for working by electricity, and during the past week the Board of Trade inspection of the Swansea electric tramways has taken place, and these lines will be worked by electricity very shortly. We hope at a very early date also to open further lines of the Potteries Company and the Dudley and Stourbridge Company, some of the Dudley and Wolverhampton tramways, the Kinver light railways, and the Tynemouth tramways and light railways, and we are well under way with the construction of the Devonport tramways, the Gateshead tramways, the Merthyr tramways and electric lighting, the Middleton light railways, and the Poole light railways. I now move the adoption of the report and accounts, and the payment of the dividends recommended in the report.

The Right Hon. Lord RATHMORE seconded the resolution.

A SHAREHOLDER said they had heard with great satisfaction what the chairman had said with respect to the question of reserve, because he (the speaker) was perfectly certain that the only way in which a company like theirs could be carried on successfully was by having a very large reserve. For a great many years he had been a shareholder in a company admirably managed and of very high position—the Telegraph Construction and Maintenance Co.—the secret of whose success had been, he believed, entirely owing to the fact that the directors had always insisted on having a very large reserve. The superannuation fund for the staff would be regarded by the shareholders as extremely satisfactory. It was obvious that a company such as theirs must require an enormous amount of organisation and work on the part of the officials, and it was therefore very important that these officials should feel that their position was a permanent one. He was only surprised at the moderate amount which had been mentioned (£2,000) for the company's contribution to the fund. He resided at Brighton, and knew something about the Brighton and Shoreham tramways, worked by horses. He was convinced that these tramways could be made a source of very considerable revenue if they were worked by electricity.

The CHAIRMAN: I am well acquainted with the Brighton and Shoreham tramways, as to which I agree there are great possibilities; but the reason we leave this matter *in statu quo* is because we have the fullest expectation and desire to equip that line electrically. Unfortunately, however, we have not been able to come to terms with the local authorities.

A SHAREHOLDER said he did not know whether other shareholders agreed with him, but in view of the conditions of the Tramways Act, it seemed to him that it would be better if the directors could see their way to keep a larger proportion of the reserve out of the business.

The CHAIRMAN: It is absolutely impossible in a business like this that we can leave our money idle; all that we can do is to see that we are covered by the judicious investment of a very large amount of our assets in sound securities.

The motion was then unanimously adopted.

A resolution to establish the superannuation fund was also approved.

Sir C. Rivers Wilson and the Hon. Sir C. W. Fremantle, K.C.B., were re-elected directors, and the auditor having been reappointed, the meeting became extraordinary.

The proposed additions to the capital of the company were agreed to, and resolutions were passed approving the proposed Barnsley and District Light Railways (Extensions) Order, the proposed Durham and District Light Railways Order, the proposed Jarrow and South Shields Light Railways Order, the proposed Kingston, Surbiton and District Light Railways (Extension) Order, and the proposed Sheerness and District Light Railway Order.

A hearty vote of thanks to the chairman and directors was carried unanimously, and the proceedings terminated.

Bastian Meter Co. (Ltd.).

The second annual report of the directors of this company, made up to Feb. 28, states that there was a profit of £388. 13s. 3d., against a loss on the previous year of £2,227. 16s. 11d. During the first six months of the year under review the company was worked at a somewhat heavy loss, but nearly the whole of this was recouped out of the profits made on the second half-year's trading, when orders increased more than fourfold. The electrical installation at Holbein House has been let on lease at a satisfactory rental, and the company is thereby relieved of any further trouble or expense in connection with that department of the business. Expenditure on experiments has been very small, as compared with the amount previously expended; and this item is likely to continue to decrease. The prospects for the coming year appear to be most satisfactory. Markets are being opened up abroad, particularly on the Continent and in Australia. A licence to work the company's patents in Germany has been arranged on satisfactory terms, and agencies have been established for Belgium, Holland, Italy, and Western Australia. Although the Board of Trade certificate for the Bastian meter is not yet in the company's possession, the directors have obtained authority to state that the meter has been officially approved by the Board of Trade.

Electric and General Investment Co. (Ltd.).

The report of the directors for the year ended May 31 states that the gross profit on the transactions of the year was £19,796. 3s., and after deducting all general charges, and interim dividend paid on the ordinary shares, there remains a net balance of £14,711. 8s. 1d. Of this sum the directors propose to carry £711. 8s. 1d. to contingencies fund, leaving £14,000 available for distribution as follows: Dividend of 5s. per share on the ordinary shares for the year (of which 2s. per share was paid ad interim in December), £3,000, together with a bonus of 4s. per share (£4,000); dividend of £30 per share on the founders' shares (£3,000), together with a bonus of £40 per share (£4,000). (In each case subject to deduction of tax.) No distribution in respect of the founders' shares reserve fund or the ordinary shares reserve fund will be made.

HARROW ELECTRIC LIGHT AND POWER CO. (LTD.)—The annual meeting of this company was held at Harrow on Thursday last. The directors' report states that the steady progress made by the company from its start has been continued during the past year. The equivalent of 2,985 8 c.p. lamps was connected, against 2,715 in the previous year; the number of customers was 92, and the units sold 113,551, compared with 58 and 79,419. The total receipts were £3,663. 5s 7d., against £2,786. 0s. 4d. Owing to increased demand a new 150 kw. steam dynamo and an electric pump have been ordered, the dynamo to be ready in September, and the pump has been already fixed. The boiler ordered in 1898 was erected during the year. Besides the reduction, since Lady Day, 1899, in price from 8d. to 7d. per unit for current supplied for lighting, the company have supplied current for arc lamps and heating and cooking purposes at 4d. per unit. The works cost for the year has been reduced to 2·4d. per unit sold. The total cost of extensions made during the year was £3,152. 13s. 10d. During the year 73 houses have been wired for consumers on the rental system, against 34 in 1898. The wiring business has increased so rapidly that the directors have decided to have their own wiring department in addition to employing Mr. Tate, who had been carrying out all the work previously. The new department was started at the beginning of 1900. The District Council have made application for a provisional order for Wealdstone on the terms of the company paying all expenses, and the Council transferring the order to them on the same terms as the original order, obtained in 1895 for the same district. The Board of Trade have now granted the order, and the confirmatory bill has been passed by the House of Lords. Prepayment meters have been supplied to consumers who desire them, and have been satisfactory, but they have not been largely taken up. Further capital being needed, the directors propose that the authorised capital be increased by £15,000, and that one-third of the increase be constituted 4½ per cent. preference shares. The sum available for dividend, after paying interest on debentures, mortgages, &c., was £1,296. 14s. 3d. £25 was written off leasehold property, £425 placed to depreciation of plant, 4½ per cent. paid on the Preference shares issued to end of year, and a dividend of 3½ per cent. was paid on the ordinary shares, absorbing £745. 5s. 5d., leaving £8. 14s. 5d. to be carried forward. The report was adopted.

MEXICO ELECTRIC TRAMWAYS (LTD.)—The general meeting was held on Wednesday. The chairman (Col. Sir C. Ewan-Smith) said the opening months of 1900 had been marked by some incidents bearing directly upon the fortunes of the company. At the close of last year the directors decided to send out the Hon. Chandos S. Stanhope to Mexico. Mr. Stanhope left England in November, 1899, with complete instructions, and his mission had been a perfect success. Shortly after Mr. Stanhope's arrival, the former board in Mexico was entirely reconstructed, but Mr. A. E. Worswick remained the chief resident engineer, Mr. Brandford, the former manager, resigned, and Mr. Clegg became manager of the company. Mr. Stanhope had negotiated an agreement with the municipality of Mexico, to remain in force for 10 years, under which the entire obligations of the Mexican Tramways Company are commuted for an annual fixed sum. Considerable progress had been made in the conversion of the entire system to electric working during 1899. On Jan. 15 the first section of the system completed for electric traction (from the city to Tacubaya) was formally opened. Since that date experience had shown them that the electric cars were earning for themselves an ever-increasing popularity. In every instance electric traction had been found to work satisfactorily. The conversion of the remaining portions of the system was being rapidly proceeded with, and the necessity that might afterwards present itself for further extensions, in order to meet the convenience of the public, was not being lost sight of.

WELSBACH INCANDESCENT GAS LIGHT CO. (LTD.)—At the annual meeting of this company, the chairman (Sir Henry C. Burdett, K.C.B.) referred to the arrangement with Dr. Auer and to the alteration of the statutes of the Austrian company providing for the establishment in one company of the gas and electricity undertaking. At the statutory meeting he stated that Dr. Auer had agreed to, and the statutes provided for, the acquisition and realisation of all inventions of Dr. Auer and the patents and licences for the same which had reference not only to electric lighting but to electric power transmission and the supply of current. That statement was a verbatim extract from the report of the Auer committee, which made the arrangement with Dr. Auer for the acquirement of the electric light. It had been urged, but in his view without justification, that this sentence might be read as meaning that Dr. Auer had sold all his inventions in the electric field of every kind, present and future, to the Austrian company, without knowledge as to their value or any further consideration for their acquisition. His words conveyed no such meaning, as to the power to acquire could only be exercised when the new inventions in the electric field were ready for commercial purposes, when alone it would be possible to fix the price at which they should be taken over by the Austrian company. It was, however, very important, in his judgment, to get Dr. Auer to consent to the insertion of this power for the acquisition, upon terms to be subsequently agreed on, of all his inventions in the electric field, because that implied that he would, in the first instance so offer them to the Austrian company. He had every reason to know that since Dr. Auer agreed to hand over his new electric light to the Vienna company he had continuously worked at the many problems which presented themselves. He had great pleasure in informing them that Dr. Auer had sent over Mr. Kuschenitz with his new electric lamp, which had been installed for the shareholders' inspection. They might further naturally desire to hear when the lamp would be available for use by the public. The last communication received from Dr. Auer on the subject intimated that the Osmium lamp would come into commercial working in the autumn. He hoped that the electric lamp would give every satisfaction, and that the shareholders would recognise that they had every reason to thank Dr. Auer for his close attention to the development of that lamp.

CITY NOTES.

MEMORANDA.—Bank rate 3 per cent. (June 14, 1900). Price of silver 27 1/16d. per oz. (June 21). Consols (2 3/4 per cent.) 100 3/8—100 7/8 for money, 100 13/16—100 15/16 for account; 2 1/2 per cent. 99 1/2—99 3/4 (June 21). Stock Exchange Settling Day: Consols, July 4; Stocks and Shares Continuation Days, June 26 and July 10; Ticket Days, June 27 and July 11; Pay Days, June 28 and July 12; Mining Share Carry-over Days, June 25 and July 9.

AFRICAN DIRECT TELEGRAPH CO. (LTD.)—The coupons on this company's 4 per cent. mortgage debentures to bearer, due July 1, will be paid on and after 2nd prox., at Parr's Bank (Ltd.), Bartholomew-lane, London, E.C. The debenture register will be closed from 25th to 30th inst. inclusive.

BROMLEY (KENT) ELECTRIC LIGHT AND POWER CO. (LTD.)—It has been resolved to increase the capital of this company from £20,000 to £50,000, in £5 shares. A confirmatory meeting will be held on July 2.

EASTERN EXTENSION, AUSTRALASIAN, AND CHINA TELEGRAPH CO. (LTD.)—The coupons on this company's 5 per cent. Australian Government subsidy debentures due July 2 will be paid at Messrs. Barclay & Co.'s Bank, 54, Lombard-street, London, E.C.

GREAT NORTHERN TELEGRAPH CO. (LTD.)—Coupons due July 1 on this company's shares will be paid by Messrs. C. J. Hambro & Sons, 70, Old Broad-street, London, E.C.

NEW GERMAN COMPANY.—The German business of the well-known firm of Brown, Boveri & Co., Baden, Switzerland, has been formed into a joint stock company, with a capital of £300,000.

PACIFIC AND EUROPEAN TELEGRAPH CO. (LTD.)—The coupons on this company's 4 per cent. guaranteed debentures due 30th inst. will be paid at Parr's Bank (Ltd.), Bartholomew-lane, London, E.C.

REDUCTION OF CAPITAL.—Sanction has been given for the reduction of the capital of John Kirkcaldy, Ltd. (makers of feed water heaters, evaporators and surface condensers), from £50,000 to £30,000. The company was incorporated in 1886, and the vendor now agrees to surrender £1,000 £10 shares.

STOCK EXCHANGE NOTICE.—27th inst., has been appointed a special settling day in the further issue of 10,000 ordinary £5 fully-paid shares (Nos. 20,001 to 30,000) of *Callender's Cable and Construction Co. (Ltd.)* and the securities have been ordered to be quoted in the official list.

WESTERN TELEGRAPH CO. (LTD.)—Coupons on this company's second issue of 5 per cent. debentures, due 30th inst., will be paid at Parr's Bank (Ltd.), Bartholomew-lane, London, E.C.

NOTES.

WE tender our sincere and hearty congratulations to Dr. OLIVER J. LODGE upon his nomination to the post of Principal of the recently-constituted University of Birmingham. The appointment is officially announced in the following terms, received by the Secretary of the Birmingham University from the Board of Education :—

HER MAJESTY, in pursuance of the provisions of the charter of the University of Birmingham, is pleased to appoint OLIVER J. LODGE, Esq., DSc., LL.D., F.R.S., Professor of Experimental Physics in the University College, Liverpool, to be Principal of the University of Birmingham.—A. W. FITZROY.

PROF. LODGE is so well known to our readers, both as a contributor to our columns and as a leader of the vanguard of physical science in this country, that it is superfluous to descant now upon the claims which his career makes upon this dignified post. The principal of a modern university needs to be a man who, on the one hand, is not too much wedded to the ancient tradition of university curricula, or, on the other hand, too restlessly anxious to uproot all these traditions and implant nothing but modern utilitarian methods. Such a requirement is abundantly fulfilled by the intellectual qualifications of Dr. LODGE, whose scientific researches constitute only the most salient feature of a mind abounding in diversified talents.

THE proceedings of the Select Committee on the Electric Power Bills, presided over by Sir JAMES KITSON, reached a critical stage yesterday afternoon, when an important announcement was made. At the conclusion of the evidence for the South Wales Electrical Power Distributing Company Bill, and after the Committee Room had been cleared for about five minutes and the public re-admitted, Sir JAMES KITSON stated that the preamble of the South Wales Bill was proved. He added that for convenience he might announce—though that business was not down for yesterday—that the preamble of the Durham and Lancashire Electric Power Bills had been proved to the satisfaction of the Committee, but that the preamble of the Tyneside Bill had not been proved. It was further announced that it is the intention of the Committee, so far as may be possible, to insert the same conditions in each of the bills carried forward.

IN our Contemporary Electrical Science notes this week a short account is given of another sensational discovery by P. LENARD, which forms a becoming sequel to his discovery in 1895 of the penetrative power and photographic action of cathode rays. That discovery was shortly afterwards crowned by the discovery of the Röntgen rays. The *tour de force* which LENARD accomplished in 1895 was to obtain cathode rays in the open air, outside the tube in which they were generated. He now obtains them in an "absolute vacuum"—or that which with our present resources stands for such—in which no electric discharge has hitherto been thought possible. The discharge of a negatively-charged electrode takes place instantly in such a vacuum, if the electrode in question is illuminated with ultra-violet light. The effect of the light is annulled by interposing a mica plate. A positively charged electrode retains its charge. That cathode rays are really in question is proved by the rectilinear propagation of the discharge and by its magnetic deflection. The only proof outstanding is the fluorescence of the walls of the tube, which has not yet been observed. The rays are the slowest yet discovered, their speed being only one-thirtieth of the velocity of light.

LENARD'S new discovery sheds a flood of light on a number of photo-electric phenomena which have hitherto been obscure. He does not seem to have made any experiments with polarised light, although such experiments are called for by ELSTER and GEITEL'S work. The precise mechanism by which a beam of light is enabled to ionise a charged metal

Digitized by Google

not immersed in a gaseous medium will form a fascinating subject of research. Such an electrified body gives out cathode rays which at ordinary pressures will of course be absorbed by the surrounding air, and will in turn make that air conducting. This explains the influence of ultra-violet light in lowering the spark potential. Not only is the production of cathode rays now independent of the pressure of the gas; it is also independent of the potential of the cathode, so long as that is negative. This would appear to place at our disposal a new form of "current valve," simpler and more reliable than the aluminium cell. Like LENARD'S former discovery, the present one is not such as would appeal to the man in the street. But to the electrician its significance is of the greatest moment. The connection between light and electricity teems with vast possibilities, and at no previous time have these possibilities appeared nearer to their realisation.

A LETTER from Dr. SILVANUS P. THOMPSON in *The Times* of Tuesday last complains of the rise in prices of gas in London, and suggests as a remedy that municipalities or rival companies should undertake to supply houses and power users with non-illuminating gas in competition with the existing gas companies. The non-illuminating gas, he says, could not only be used for propelling gas engines and supplying gas stoves, but might also be used as a lighting agent, by means of incandescent mantles. We think the remedy is almost, if not quite, as bad as the disease. A weakness in gas companies is that they tacitly admit that a rise in the price of coal affects them so seriously that they must put up the price of gas. But if illuminating gas companies are really thus affected, the manufacturers of non-illuminating gas would be equally liable to raise their prices whenever coal might go up in price. It is the strength of electric light companies that the price of coal so little affects the producing cost of their commodity. We do not, of course, imply that the serious rise in the price of coal has not affected electric light companies at all, but those who are familiar with the analyses of electricity works accounts, published in our columns from week to week, will have no difficulty in understanding how small is the influence of a considerable variation in the price of coal upon the total cost, and therefore the selling price of electric power. Dr. SILVANUS THOMPSON'S heroic remedy is unnecessary. All who are dissatisfied with gas should use electricity.

IN an editorial note in our last issue we briefly referred to the superannuation scheme recently developed by the British Electric Traction Co. An interesting letter from Mr. E. GARCKE, in our correspondence columns this week, announces that the advantages of this scheme are not restricted to the staff of the associated undertakings of the British Electric Traction Co., as the directors of that company invite other electrical companies which may be so disposed to join the scheme. We are quite in agreement with Mr. GARCKE that there must be other electrical undertakings, whether tramway companies or only indirectly associated with tramway work, the officers and staffs of which would be glad to reap the advantages of this scheme. Mr. GARCKE states that the affairs of the Association will be managed by a representative committee on independent lines, with Mr. W. G. BOND as secretary.

THE Typewriting Telegraph Corporation (Ltd.), which has been registered with a share capital of £100,000, in £1 ordinary shares, has been formed to acquire the patents and develop the typewriting telegraph instrument invented by Mr. W. S. STELJES. An illustrated description appears in an article we publish this week. The present issue comprises 80,000 shares, of which 26,666 will be taken by the vendors in part payment of the purchase, the remaining 53,334 having been offered to the public for subscription. Among the directors are Sir JAMES FERGUSON, chairman, and Mr. C. E. SPAGNOLETTI, both well known in telegraphic circles. The business manager is Mr. W. T. GOOLDEN, a prominent electrical engineer, while the consulting engineers, Messrs. MORDEY and DAWBARN, are also well known to our readers. The invention with which this promotion is associated promises to satisfy a considerable want as an instrument for recording messages without the use of the Morse or any similar code. There should be an extensive market for a satisfactory instrument of this class, and Mr. STELJES certainly has brought to bear upon his invention a high degree of technical skill and experience. The promotion, which appears to be on eminently satisfactory lines, financially speaking, should prove a great success.

Electrical Engineers (R.E.) Volunteers at the Front.—It is reported that Serg. Wander has been taken prisoner at Vredefort.

Personal.—Mr. Shelford Bidwell, F.R.S., has been admitted to the degree of Doctor of Science in Cambridge University.

Erratum.—In the "Contemporary Electrical Science" note "Conductivity in a Vacuum Tube," last week, p. 318, read "resistances" for "conductivities" in the last line but two.

Röntgen Society.—The Annual General Meeting of this Society will be held at 20, Hanover-square on Thursday next, July 5, at 8 p.m. A presidential address will be read by Mr. Wilson Noble.

British Association.—At a public meeting held in Belfast recently it was decided to invite the British Association to visit Belfast in 1902. The last meeting in Belfast took place in 1874 under the presidency of Prof. Tyndall.

Azores–United States Cable.—Messrs. Siemens Bros. & Co.'s c.s. "Faraday" sails on Monday with the balance of the Commercial Cable Co.'s cable from Fayal (Azores) to Canso, (Nova Scotia). The cable is already laid 600 miles out from Canso.

Appointment Vacant.—The chair of physics at the University College, Liverpool, is vacant by the resignation of Dr. Oliver Lodge, who has been appointed Principal of the University of Birmingham. Applications to be made to the registrar by July 16.

Lift Accident on the City and South London Railway.—We learn that the lift accident at the London Bridge station of the City and South London Railway, which occurred at 6 o'clock yesterday morning, was not due to any defect in the electrical arrangements of the lift.

The New Physical Laboratory at Owens College.—The new and splendidly equipped physical laboratory recently built for the Owens College, Manchester, is to be opened by Lord Rayleigh this afternoon at 2.30 o'clock. The event is to be followed in the evening by a conversazione.

Digitized by Google

Wireless Telegraphy.—It is stated that the Government is conducting experiments in wireless telegraphy between Swanage and St. Catherine's Lighthouse. Wireless telegraph stations are also, by the instruction of the chief signal service officer of the United States, to be established in the harbour of San Francisco, in Porto Rico and in the Philippines.

American Association for the Advancement of Science.—The annual meeting of this Association has been arranged to be held earlier than usual this year, viz, from the 25th to 29th inst. The change is partly to accommodate members intending to visit Paris and partly to avoid the excessive discomfort of sitting through long discussions in the dog days

Water Power Electric Traction in Newfoundland.—Power for the new electric tramways at St. John's, Newfoundland, is transmitted over a distance of 9 miles at 15,000 volts. 1,600 H.P. is generated at a waterfall under a head of 185ft. with turbines of the "Victor" type and Westinghouse generating machinery. The tramway is 7 miles long, and is equipped with 20 cars.

Cable Interruptions:—	Date of Interruption.
Latakia—Cyprus	June 21, 1899
Cayenne—Pinhieros	Oct. 11, 1899
Tangier—Tarifa	Jan. 3, 1900
Paramaribo—Cayenne	Feb. 16, 1900
Ceara—Maranham	Feb. 20, 1900
Pará—Maranham	Mar. 2, 1900
Môle-St. Nicolas—Cap Haitien	Mar. 7, 1900

Optical Treatment of Lupus.—Prof. Sinsen's method of treating skin disease by means of intense light rays projected on the patient has recently been introduced into the London Hospital, where it has been on trial for the last three weeks. The introduction of this method into this country is primarily due to H.R.H. the Princess of Wales, who took great interest in it during her visit to Copenhagen, where it has been practised for some time.

Employment of Electricity in Russian Coast Fortifications.—According to the *United Service Gazette*, all the electrical energy required for lighting purposes, firing guns, &c., in the Russian coast fortifications is provided by accumulators, which have to be taken to a dynamo outside the fort in order to be recharged. The cells at Cronstadt and Batoum are needing renewal, and the question is under discussion whether each fort should not now be supplied with its own generating plant.

Telegraphic Communication with China.—The Eastern and Great Northern Telegraph Companies notify that the British Government have agreed to allow all war vessels passing between Chefoo and Taku to carry telegrams. Messages for Taku and beyond can be accepted to go by this route at sender's risk. Communication between Shanghai and Chefoo is at present open by means of landlines belonging to the Chinese Telegraph Administration, but nothing is known of the state of communication beyond Taku. This is the first occasion on which any Government has sanctioned the conveyance of telegrams by warships.

Telegraphing Telephone Messages.—On Monday last, in the House of Commons, Mr. Henniker Heaton asked the Secretary to the Treasury, as representing the Postmaster-General, whether postmasters had been instructed not to forward telegraphic messages over the wires of the National Telephone Co. Mr. Hanbury replied that the Post Office did not now deliver telegrams by telephone to subscribers of the National Telephone Co., with the exception that it has not withdrawn this privilege from any subscriber to whom it has been already granted. Apropos of this matter, we understand that the view of the National Telephone Co. is that this extraordinary new departure is illegal and a breach of the terms of their contract with the Post Office.

Institution of Mechanical Engineers.—The summer meeting of this Institution has been held at Westminster this week, commencing last Wednesday and concluding to-day. The proceedings commenced at 10:30 a.m. with a reception of members of the American Society of Mechanical Engineers. The reading and discussion of Papers followed, the first item being the adjourned discussion of Prof. H. S. Hele-Shaw's Paper on "Road Locomotion." Other Papers included one on "Recent Locomotive Practice in France," by M. E. Sauvage; one on "Polyphase Electric Traction," by Prof. C. A. Carus Wilson; and a Paper entitled "Observations on an Improved Glass Revealer for Studying Condensation in Steam-engine Cylinders and Rendering the Effects Visible," by Mr. Bryan Donkin. In the afternoon the members paid visits to the various electrical and other engineering works, and in the evening it celebrated its annual dinner at the Hotel Cecil. On Thursday the reading and discussion of Papers was continued during the morning, and in the afternoon visits were again paid to engineering works in and around London. To day the Institution will enjoy a number of excursions to various places of interest, including Messrs. Willans & Robinson's Works at Rugby. This evening at nine o'clock the Institution will hold its annual conversazione at its buildings at Storey's Gate.

The Paris Exhibition.—At about two o'clock on Monday afternoon the supply of electricity to the greater part of the Champ de Mars section of the Exhibition was interrupted by the bursting of a pipe conveying feed-water to one of the batteries of boilers which supply steam to the generating sets furnishing current for light and power. The machines affected were continuous-current machines, and in ordinary circumstances the effects of the accident would not have been felt at all, as three other large continuous-current units are supplied from another group of boilers. These sets are the only three English generating sets for supplying electric power to the Exhibition, but unfortunately they are also almost the only machines which are not yet in running order. Most of the continuous current circuits were, therefore, dead until the galleries closed at seven o'clock, but with the help of temporary make-shifts sufficient current could be obtained for lighting the grounds and restaurants in the evening, and also to supply the "Salle des Illusions" for a Press view between 4 o'clock and 5 o'clock. This "Salle des Illusions" is a hexagonal hall, the walls of which are covered with mirrors, and whose roof is a fine gilt dome. Hundreds of incandescent lamps of different colours are tastefully arranged on the dome in such a manner that they are not visible until lit, and beautiful effects are obtained by switching on different combinations of these lamps. The demonstration although somewhat belated was most successful, and it was repeated with equal success on Tuesday.

The Thames Ironworks.—A visit was made by about 90 of the members of the Society of Engineers on the 20th inst. to the Thames Ironworks at Blackwall. These works have a frontage on the river Thames and extend some distance up Bow Creek. They are the growth of more than half a century and now cover an area of some 30 acres on the Essex side and 3 acres on the Middlesex side of the creek. They are divided into four departments, of which the shipbuilding is the oldest and most important. The other departments are the civil engineering, the electrical engineering, and the dry docks. The electrical engineering department undertakes electric light and power installations, and has also carried out the electrical equipment of vessels built by the company. Here the visitors witnessed the production of general electrical machinery and apparatus, including dynamos, motors, electric fans, portable electrical drilling machines, searchlight projectors, switches and switchboards. In consequence of the transference of the marine engineering department to the newly acquired works at Greenwich, the present machine shops at the Orchard-yard will be devoted almost entirely to electrical manufactures, and the resources of the electrical engineering department will be greatly augmented. A central generating station has been established in the works for supplying current for the several departments. The installation consists of three locomotive and two gunboat boilers aggregating 600 I.H.P. There are nine sets of engines and dynamos aggregating 350 kw., three sets having been built by the Thames Ironworks. Distribution of current is effected on the three-wire system, the main cables to the distributing centres being of vulcanised india-rubber insulation laid in cast-iron pipes underground. The electric current generated is chiefly used for lighting purposes, but is also supplied to the motors employed in the works for driving machinery. The use of electricity for power purposes is in course of extension.

THE CENTRAL LONDON RAILWAY.

(*Continued from page 280.*)

Opening Ceremony.—We suspend our description of this railway in order to give some account of the opening ceremony, which took place on Wednesday afternoon. The ceremony was performed by H.R.H. the Prince of Wales, in the presence of a number of distinguished guests and the chief officials of the associated companies. Among these were Sir Henry Oakley, chairman of the Central London Railway Co., and other members of the board, Sir Benjamin Baker and Mr. Basil Mott, the engineers of the line, the chairmen of a large number of railway companies, Sir M. Hicks-Beach, Chancellor of the Exchequer, Mr. Ritchie, President of the Board of Trade, Mr. Chaplin, President of the Local Government Board, Sir Courtenay Boyle, Permanent Secretary of the Board of Trade, Mr. F. J. S. Hopwood, Secretary to the Railway Department of the Board of Trade, Mr. F. Huddleston, chief engineer of the Electric Traction Co., by whom the construction and equipment of the line has been carried out, Mr. H. H. Holt, resident engineer in charge of the work on behalf of the same company, and a number of other well-known persons.

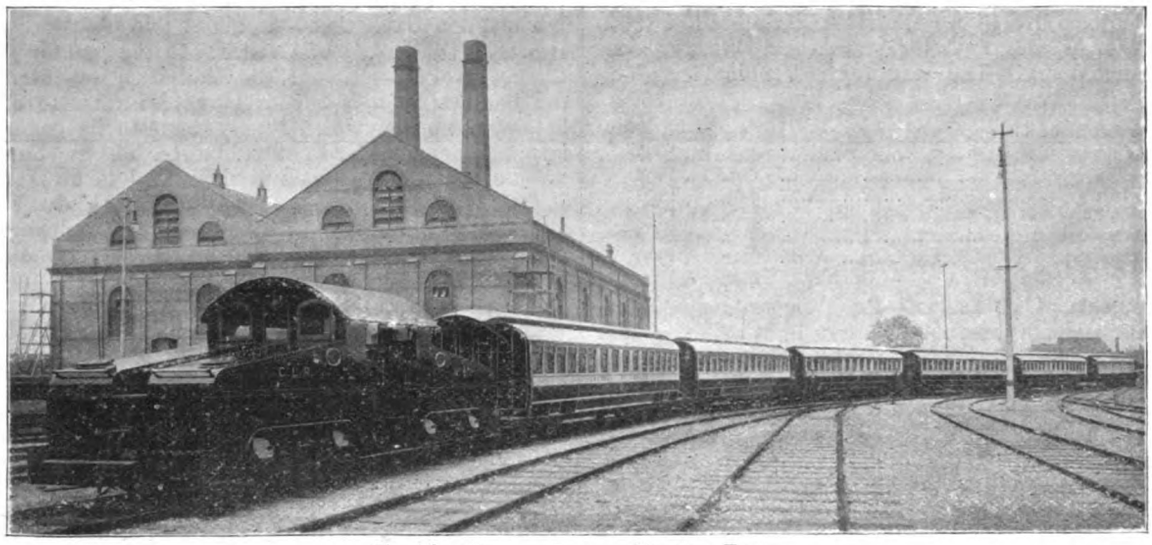

FIG. 12.—CENTRAL LONDON RAILWAY TRAIN.

The Prince of Wales, accompanied by Sir Francis Knollys and Captain Holford, arrived at the City terminus of the railway at 3.30 p.m., and descended to the line by one of the electric elevators. Prior to this a train-load of guests had been despatched to Shepherd's Bush. The Royal train performed the journey to Shepherd's Bush station, without stopping, in less than 19 minutes, and proceeded up the gradient to the depôt and power station, where it arrived in 22 minutes from the time of starting. The speed of the train was, therefore, about 15 miles an hour, but we understand that Lieut.-Col. Yorke and Mr. A. P. Trotter, who have inspected the line on behalf of the Board of Trade, consider that a much higher speed might be attained with perfect safety.

On reaching the power station, and after inspecting the generating machinery, His Royal Highness declared the line open in the following felicitous speech :—

My Lords and Gentlemen,—I have great pleasure in declaring the Central London Railway open. It has given me much pleasure to take part in to-day's proceedings. I wish to drink "Success to the undertaking," and I congratulate Sir Benjamin Baker, the eminent engineer, who has constructed this great railway. I have but little doubt that it will be an immense boon to London, and I am sure you will all join with me in wishing success to the company.

We understand that the opening of the line to the public will not take place until about the middle of next month, but the exact date has not yet been fixed. Although the line is practically completed and ready for traffic, there are one or two minor matters to be attended to, and, apart from this, the directors are particularly anxious not to open the line until the staff has been sufficiently drilled to allow of the railway handling a large body of traffic without risk of delays.

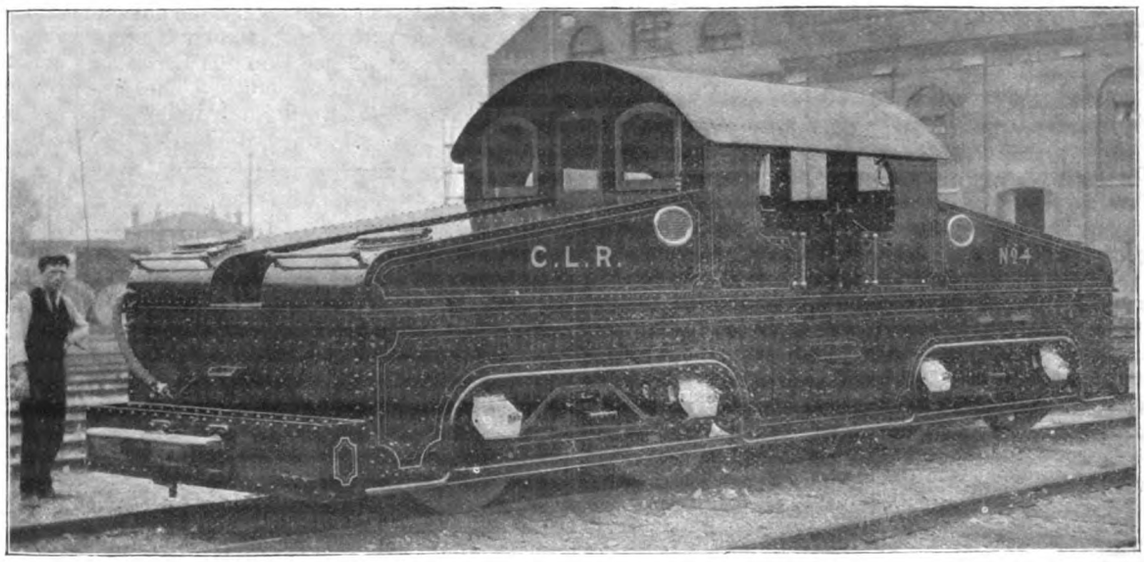

FIG. 13.—CENTRAL LONDON RAILWAY LOCOMOTIVE.

Our illustrations this week show the general construction of the trains, locomotives, stations and tunnel work of this the newest and best of London's underground railways.

CONTEMPORARY ELECTRICAL SCIENCE.

[Compiled by E. E. Fournier d'Albe.]

Duplex Wave Telegraphy.—A. Turpain has devised a system of superimposing a wave message upon an ordinary continuous-current telegram without interference, and so utilising the same wire for two simultaneous messages without going to the trouble of constructing dummy circuits. The wave message is sent by ordinary wire waves, but in order to prevent it rushing into the Morse electromagnet and destroying its insulation, the Morse receiver is enclosed in a metallic screen in contact with the magnet winding, and an electrolytic cell or an iron coil is also added to the receiving apparatus in order to force the waves into the line wire. The system can be applied either duplex or diplex fashion. It has been tested over a line of 350 metres of ordinary telegraph wire, and appears to have answered well. It was also applied to signalling over a guard-wire of the Bordeaux-les-Chartrons electric railway, and does not appear to have been affected by the proximity of strong currents of the latter. But, on the other hand, no guarantee is given that existing telephone circuits would not be influenced, as we know they are influenced, by other ingenious French devices.

[A. Turpain, *Comptes Rendus*, May 14, 1900.]

Production of Cathode Rays by Ultra-Violet Light.—P. Lenard announces an important development of the connection between electricity and light in the discovery that the discharge of electrified bodies by ultra-violet light is due to the production of cathode rays by the impact of the light. The hitherto accepted theory that the discharge was due to the mechanical disintegration of the electrode is rendered invalid by the fact that this would require the transfer of an amount of material such as could not fail to be detected by the spectroscope, and the spectroscope makes no such indication. The constant increase of the discharge with the exhaustion, as well as the strictly one-sided character of the discharge, suggested the probability of cathode rays being concerned in it. This was as good as proved by the following experiment: A vacuum tube was furnished with two electrodes, and exhausted until it failed to allow any discharge to pass. One of the electrodes was exposed to the ultra-violet light furnished by a spark-gap with zinc terminals. When the electrode was charged negatively it was instantly discharged by the ultra-violet light. A positive charge, on the other hand, was retained indefinitely. The potential is of no account, except that the discharge is not so complete at low potentials, probably on account of a lack of energy of the cathode rays. That the electric charge proceeds in the form of rays is shown by the fact that if it is made to traverse a perforated electrode, a charge is received on an electrode in a line with the hole, but not on a lateral one. The beam can, however, be brought to impinge upon the lateral electrode by magnetic deflection. The ratio e/m comes out as high as $11{\cdot}5 \times 10^{-6}$, and the velocity as low as $\frac{1}{30}$th of the velocity of light. The rays are not sufficiently intense to produce phosphorence of the walls of the tube. But it is now possible to produce these rays in an "absolute" vacuum, and with any given difference of potential.

[P. Lenard, *Ann. der Physick*, No. 6, 1900.]

Current Intensity in Vacuum Tubes.—H. A. Wilson has conducted some investigations into the potential gradient and the conductivity of the gas in a vacuum tube by means of an elegant contrivance which enables him to shift the two probes into any part of the discharge at will. The discharge passes through a Torricellian vacuum, and an open glass tube containing the two electrodes floats on the mercury, whose surface can be raised or lowered by means of an indiarubber tube with thistle funnel. The upper electrode is connected with the outside by means of a spiral of thin brass wire. The probes enter through the side of the barometer tube. They are fixed in one position, and the electrodes are raised and lowered. The author reproduces some interesting diagrams showing the distribution of the potential gradient. Being puzzled by its sudden decrease near the anode, he substituted mercury jets for the platinum probes, but obtained the same result. He therefore attributes the sudden drop of potential at the anode, which often amounts to 35 volts, to the great rate at which the positive ions are shot off there. He also studied the conductivity of the gas at various points by the same probes, and obtained curves which confirm those of Stark (see *The Electrician*, p. 818, where, however, the ordinates represent resistance and not conductivities), except that there is no such sudden drop of resistance near the anode as is found near the cathode. But then, of course, Stark's curve is an imaginary one.

[H. A. Wilson, *Phil. Mag.*, June, 1900.]

Alternate-Current Sparking.—The impossibility of producing an alternate-current arc between metals at ordinary pressures is an important practical safeguard for alternate-current switchboards and installations generally. The causes of this immunity are made clear by the researches of L. Kallir, who photographed the sparks produced by the breaking of the circuit at various phases on a rotating photographic plate. The duration and intensity of each spark depends upon a number of circumstances, such as the shape of the terminals in contact, the facility of evaporation of the material, the speed with which the terminals are separated, and the phase at which the interruption takes place. To arrive at definite data concerning the speed of interruption the author brought about the interruption by immersing a platinum point in mercury, and letting the mercury flow away at a definite rate. Even if the instantaneous speed of interruption could not be actually found in this manner, it could, at all events, be controlled. It was found that, whatever happens, the spark is confined to one semi-period, *i.e.*, there is no alternating spark. In ordinary air the spark never exceeds one semi-period in duration. But in a vacuum, especially with strong currents, the duration of the spark may well exceed an ordinary commercial semi-period. But even then the spark is intermittent, and is confined to the odd or the even semi-periods.

[L. Kallir, *Ann. der Physik*, No. 6, 1900.]

Radium Radiation at Low Temperatures.—O. Behrendsen has examined the influence of the lowest temperatures obtainable upon the activity of "radium." His specimen was not of the most effective kind, such as Giesel's recent preparations. It did not affect the fluorescent screen, but when the bottle containing the powder was placed in front of the eye accustomed to the dark, a dim luminosity was perceivable. About half a gramme of the preparation was placed in a test tube, and an electrode of platinum was mounted just above it. The electrode was charged by a dry pile and then connected with an electrometer. The rate of discharge was measured by counting the number of seconds required by the electrometer spot to pass certain points on the scale. Such measurements were made in the open air, in liquid air, and then again at the ordinary temperature. It was found that the extreme cold produced a retardation of the discharge to over twice its former rate. On restoring the tube to the ordinary temperature the activity was found to be considerably increased. This is exactly what Lumière observed in the case of phosphorescent bodies. The increase is transient, of course. Both the author and Giesel have noticed a considerable decrease in the activity of their polonium preparations of last year.

[O. Behrendsen, *Ann. der Physik*, No. 6, 1900.]

High Thermo-electric Forces.—Ever since Seebeck's discovery of thermo-electricity, or, as he called it, the "magnetic polarisation of metals and ores by difference of temperature," it has been known that many oxides and sulphides possess high thermo-electric powers, some of them far in excess of anything found among the metals. A. Abt has systematically examined a number of these ores, such as pyrites, pyrolicsite, pyrrhotite, and chalcopyrite, between the temperatures of 0deg. and 100deg. Taking the E.M.F. developed by a bismuth-antimony couple between these temperatures as a unit, that of a pyrite chalcopyrite couple is 10·8, and that of a pyrite-galena couple as much as 13·4.

[A. Abt, *Ann. der Physik*, No. 6, 1900.]

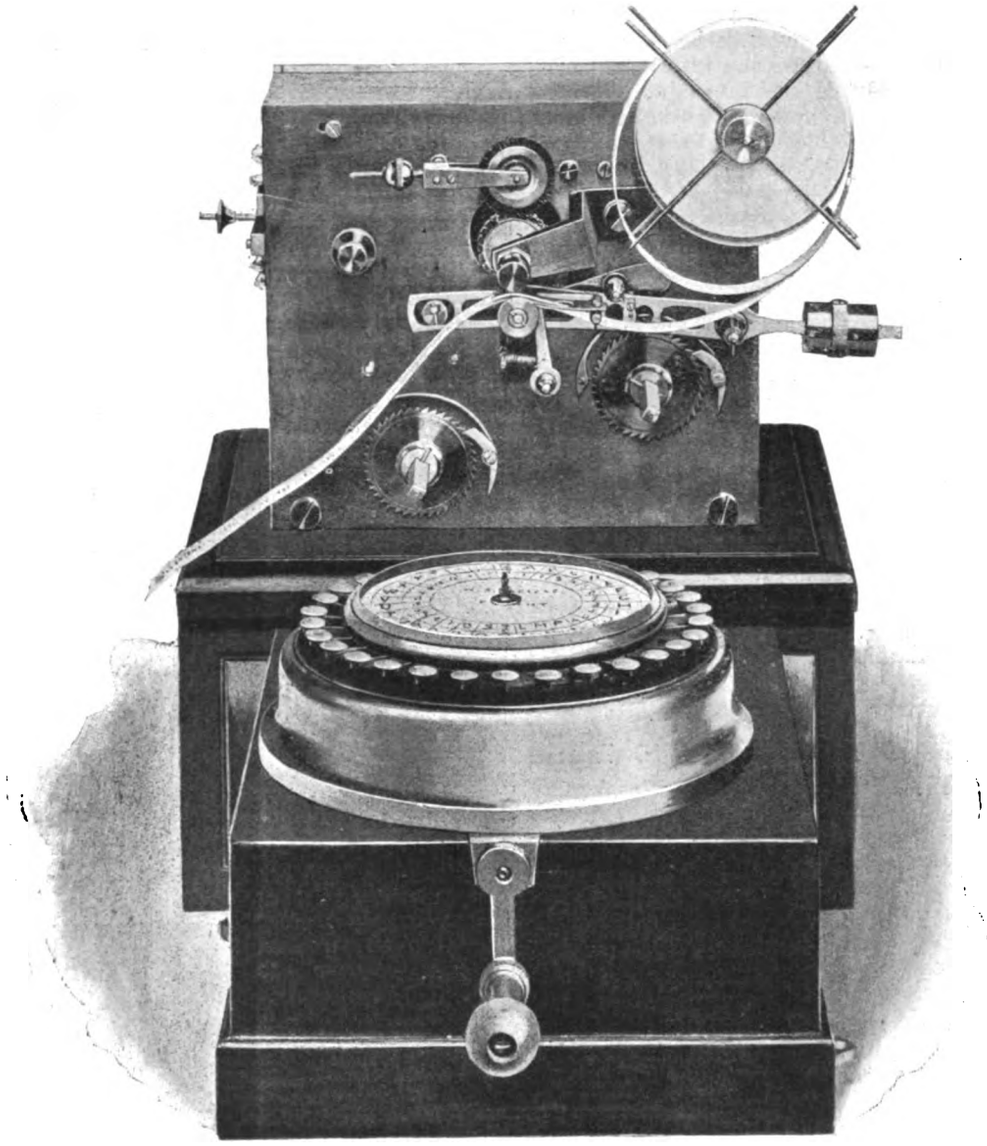
THE STELJES TYPEWRITING TELEGRAPH.

Two factors affect the design of type-printing telegraphs—two factors which appear to a great extent antagonistic, viz., speed and simplicity. On the one hand there is the ingenious Hughes instrument—valuable for public telegraph service—but the speed necessary for this is attained at the expense of complication, which not only makes the instrument costly but necessitates the employment of a skilled operator. From time to time we have described other type-printing telegraphic apparatus of more recent date, designed with a view to simplifying the work of transmitting to that of an ordinary typewriter, and necessitating practically no attention at the receiving end. In the latest addition to this class of instrument (to the description of which the present article is devoted) the mechanism and action are reduced to extreme simplicity compared with that of the Hughes instrument; but the speed of working is slow, viz., that of the Wheatstone A B C instrument, which is estimated by Preece and Sivewright to be 20 words a minute in the hands of very expert manipulators, but in ordinary practice to fall short of 10 words, and in the average not to exceed five words a minute.

The Steljes type-printer is, in fact, a modification of the A B C receiver, by means of which the letters, instead of being merely momentarily recorded by a pointer, are printed on a tape. An ordinary Wheatstone A B C transmitter is employed, of the pattern still in use by the British Post Office in many rural offices. It is only necessary here to refer briefly to the action of this well-known instrument—shown in the lower part of the illustration. On turning the handle in front, the armature of a simple magneto generator is revolved, and slowly alternating currents are sent to line, the pointer on the dial moving round from one letter to the next for each alternation. The key opposite to the desired letter is depressed, and the pointer is stopped on reaching the corresponding position while at the same time the current to line is cut off. In the Wheatstone pointer receiving instrument, the pointer moves in synchronism with the pointer of the transmitter, by means of the alternating currents; in the Steljes instrument a type wheel takes the place of the pointer. The escapement driving the type wheel is moved by a pair of electromagnets similar to those of a magneto bell, the power being obtained by a weight (or if greater portability is required by a spring, as in the illustration). The type wheel is double, the rim of one disc containing 30 letters, and the other numerals, &c.



PORTABLE PATTERN OF STELJES TYPEWRITING TELEGRAPH.

A simple mechanism is employed to move the type wheel against the paper tape at the moment the current stops. In addition to the escapement magnets and armature there is a very light aluminium armature attracted by a non-polarised magnet, which is traversed by the alternating line current. The reversals of the current are sufficiently sharp to keep this armature attracted until the current stops. At this moment, which is, of course, the one at which the type wheel is in the position for printing the desired letter, the

Digitized by Google

armature drops and permits a cam at the end of a train of wheels (driven independently of the other escapement train by a weight or spring) to make a complete revolution. The cam, as it turns, lifts the arm holding the roller over which the paper passes, presses it momentarily against the type wheel and releases it again. On the downward movement of this arm, a click fixed in the frame engages in a ratchet, and this turns the printing roller one space forward, leaving the paper ready for the next letter.

For setting all the instruments to zero there is an arm placed friction-tight on one of the wheels in the type-wheel train, which is knocked down each time the printing lever is worked, so that if the type wheels are allowed to go two or more revolutions without printing, all the instruments will be brought to zero.

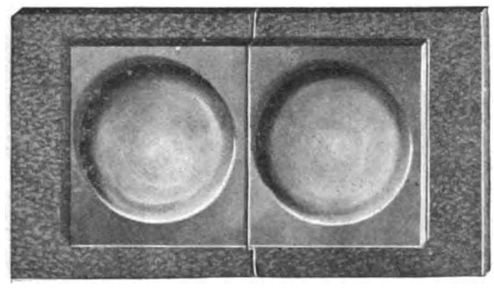
The arrangement for moving the type wheel parallel to its shaft for printing either letters or numerals is as follows: At right angles to the type wheel, and rotating with it, is a blade with a nose, and the type wheel is kept up against this blade by a light spring. When the zero key is depressed the printing lever comes in contact with this blade, and presses upwards, and the type wheel prints on the letter band. If the key opposite the zero key (between the letters N and O) is depressed, however, the blade is pushed up, and moves the type wheel forward parallel to its spindle, so that the numerals, instead of the letters, come in position above the paper.

The instrument has, we understand, undergone a trial of several months at the Post Office (in whose service Mr. Steljes formerly was), and has been used successfully on several underground circuits in different parts of London—the longest being from Hampton to Westminster through three intermediate stations. It has also been tested on a 200lb. copper overhead telephone circuit between London and Manchester, with an additional resistance of 2,000 ohms in series. The Belgian Government has also tried it with good results, we are informed, on some of their lines which are employed for simultaneous telegraphy and telephony. Steljes instruments, although not adopted by the Post Office for general telegraphic service have been put in by them on several private lines. They are also included in the official exhibit of the British Post Office at the Paris Exhibition.

THE INTERNATIONAL TRAMWAYS AND LIGHT RAILWAYS EXHIBITION.

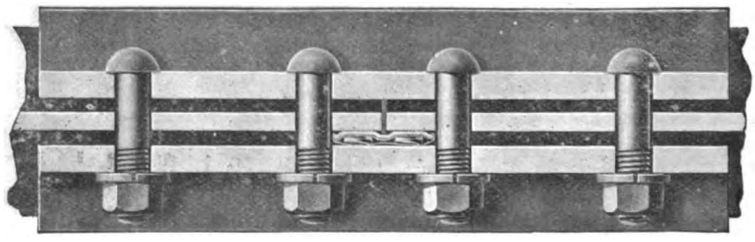
The International Tramways and Light Railways Exhibition was opened on Friday last week with a luncheon. The proceedings were commenced by a speech from the chairman, Mr. Dickinson, chairman of the London County Council, who dealt at considerable length with the economic aspects of the tramways question, more especially the problems of private versus municipal enterprise. As was, perhaps, to be expected, he expressed his adhesion to the principle that such means of transit ought to be owned by the municipalities. Mr. Dickinson maintained that the growth of the huge cities of the present day was due to these means of communication. When pointing out that effective means of locomotion are a *sine quâ non* of modern town life, and that of all modern cities of the first rank London was the most backward as regards the possession of rapid and convenient means of locomotion, the chairman was on less debatable ground. The fact that Mr. Dickinson selected one individual firm of electric tramway undertakers for special commendation by name, gave rise subsequently to a certain amount of adverse criticism on the part of those present. Mr. Dickinson was followed by Alderman Clegg and by Mr. Concanon, who devoted an amusing speech to the glorification of private enterprise and, as a director of the Dublin United Tramways Company, gave expression to legitimate patriotic pride in the success, both technical and commercial, of that undertaking. Mr. Concanon was followed by Alderman Jones, of the Dublin Corporation, who explained the admirable profit-sharing arrangement made between the Dublin Corporation and the tramways company. Then followed Sir W. H. Preece with what appeared to be the most popular speech of the occasion. Sir William explained that being an old hand at entertainments of this description, he had taken the precaution of sending his speech to the Press in advance. He therefore requested the audience to take his speech as read, moved the toast with which his name was coupled, and sat down amid prolonged applause. Several other speakers followed, amongst whom were Prof. Bryce and Prof. Perry, who gave an interesting comparison of the cost per horse-power hour of man, horse, and electricity, and the enormous reduction possible in the latter under a regular load factor.

The exhibition itself manifested plentiful evidence of unreadiness; everywhere stalls are still being fitted up, and exhibits are lying about in more or less confusion. The stalls of certain firms are, however, tolerably complete.



PLASTIC BOND.

Among these may be enumerated Messrs. R. W. Blackwell & Co., the Helios Company, Messrs. Witting Bros., and the Westinghouse Company. Messrs. Blackwell & Co.'s exhibit is indeed most admirable and complete. Practically every class of appliance connected with the electrical equipment and propulsion of tramcars is represented, and a number of interesting novelties are on view. Conspicuous among these are the contributions of the firm towards a solution of the perennial rail-bonding difficulty. Two forms of "plastic rail bond" are shown, the principal agent in both being the Edison-Brown plastic alloy. This composition, which is rather copiously displayed on the stall, is an alloy the exact composition of which is not disclosed. It is just hard enough not to run, but can be easily moulded by the fingers. Two methods of using the composition are employed. In the one two spots on each side of the division between the rails are freed from rust and silvered by rubbing



SECTION THROUGH PLASTIC BOND.

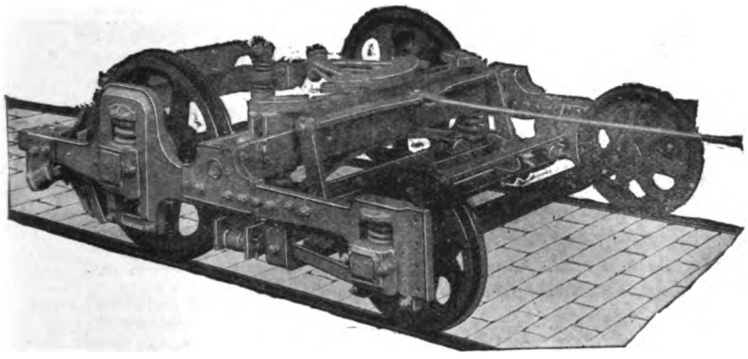
with the Edison-Brown hard alloy. Two corresponding spots on the fish-plate are similarly prepared, and between the prepared spots on rail and fish-plate a lump of the plastic amalgam is introduced and retained in position by a suitably perforated sheet of cork, and the fish-plate screwed up. In this case the fish-plate carries the current. There is also exhibited another form of the plastic bond which does not, however, differ in principle from the above. In this case the current is not carried by the fish-plate, but by a plate of rolled copper, which is provided with two bosses of plastic alloy, which are designed to make contact with the amalgamated spots on the web of the rail. These are mounted on a sheet of cork which exactly fits the web of the rail, and has two springs extending through holes in the cork, by means of

Digitized by Google

which the fish-plate is enabled to press the copper and amalgam firmly against the rails. The cork keeps out moisture and damp. It is claimed for this bond that its resistance is less than that of the same length of solid rail. An interesting exhibit is the apparatus for testing the bonds. A large welding dynamo is driven by a motor, and the current from it runs through a bonded rail. A Weston voltmeter of enormously magnified scale—its whole scale reads $\frac{3}{100}$ths of a volt—enables the drop in voltage to be measured. By this means the fact that the bond has considerably less resistance than the same length of unbonded rail is demonstrated.

Messrs. Blackwell's so-called "swing-bolster maximum traction truck" is specially designed for lines with sharp curves. These trucks are what may be termed double-bogeyed, *i.e.*, there is a bogey in front and a bogey behind, with the four large driving wheels in the middle. The car is mounted on two "bolsters," which are in reality slides arranged on either side of the driving wheels. The slides allow a certain amount of side movement, and on rounding a curve the car swings over towards the centre of curvature, so putting extra weight on the bogeys and counteracting any tendency to jump the rails.

An ingenious form of what is in reality a relay brake for use on tramcars is exhibited. In a lighter and slightly modified form it would probably prove a very useful addition to motor cars. An ordinary form of brake is applied by a chain wound up on a drum. The drum is rotated by a friction clutch which engages with one of the running wheels, and can be put on very gradually or with great rapidity. The



Maximum Traction Truck.

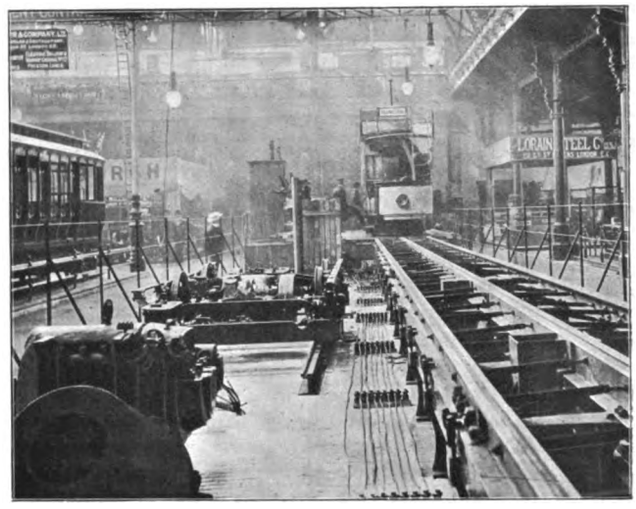
momentum of the car thus supplies the force with which the brake is applied, the action of the friction clutch being therefore that of a relay. As the *vis viva* of the car is being used up to apply the brake at the same time as the brake is stopping the car, the arresting power of the brake is very great. A fully-loaded tram-car can, it is said, be stopped on an emergency from a speed of 10 miles per hour in two yards.

Another system of dealing with the brake problem is provided by the Christensen air brake. It savours perhaps rather too much of the railway train air-brake system. There is a motor—that represents the donkey engine—and it compresses air into a receiver. When the necessary pressure is reached a relay contact cuts off the motor. When the pressure sinks below a certain point the contact mechanism puts in the motor which continues pumping as before till the normal pressure is re-established.

A feature of the Blackwell exhibit is the admirably constructed equable pressure trolley-poles. In the ordinary trolley-pole controlled by springs the upward effort increases as the pole is depressed. In these it is, within working limits, constant. This is effected by a special method of construction. A wire secured to the pole passes over a cam of varying eccentricity to a spring. As the pole is depressed the tension of the spring tending to restore it to its original position increases; the eccentricity of the cam, however, over which the wire passes diminishes, and the product of the two being constant, the force raising the pole remains the same. The pressure of the trolley against the trolley wire therefore remains within wide limits practically constant.

An interesting detail of line construction is supplied by the manganese steel crossings. The crossings have, of course, to carry double the traffic of the rails forming the ordinary track. If of the same material they would consequently wear out long before the rest. The rail ends abutting on the crossing after being planed and fitted are united, not by rivets or by bolts and nuts, but by having run round them and through holes in them a molten mass of metal. This metal in cooling draws together the different pieces of steel making a compact unit of the whole. Into this fits the manganese steel crossing, which is bolted down in position. If in spite of its extra hardness, it finally does get worn down, it may be removed and a fresh one substituted.

The Westinghouse Company exhibit a complete tramway installation in operation. A high-speed three-cylinder 120 H.P. gas engine, with electric ignition, is coupled direct to a multipolar 500-volt generator. This supplies current to a length of tramline on the underground conduit system, running the length of the hall. On this a highly-finished and well-appointed tramcar runs up and down, carrying passengers. The same company exhibit the Newell electromagnetic brake. In this apparatus an electromagnetic clutch is arranged on each side of the car, just clearing the rails. When the brake is applied the motors are disconnected from the line, and then



Westinghouse Tramway Exhibit.

run as dynamos in virtue of the momentum of the car. The current which they thereby supply is utilised to energise the electromagnetic clutch, which then clutches the rails and simultaneously applies the brakes. A feature of the Westinghouse exhibit is the pneumatic car control. A couple of dummy cars are shown in which it is applied. Each of these is provided with a motor equipment and a series parallel controller on the platform. These controllers are operated by compressed-air mechanism, which is in turn controlled by what may be called a pneumatic switchboard. The operation of the mechanism is such that whatever position the controller in one of the cars may be brought into, the other is at once brought into precisely the same position. The system is, in fact, a multiple unit system, and resembles, to a certain extent, the system introduced by Sprague, with this difference, that the controllers, which in Sprague's system are operated electrically, are in this case worked by compressed air.

The Helios Company, of Cologne, so well known on the Continent for their alternating and polyphase installations, have recently started an English branch. They were under some misunderstanding regarding the importance of the present exhibition, and their stand in consequence hardly does them justice. Their principal exhibit is a very good form of maximum current cut-out. The maximum current energises an electromagnet which, attracting an armature, throws out the main switch. The current is thereby shunted through a high-resistance carbon switch, which is subsequently broken, thereby diminishing sparking. This, of course, is not new. The novel feature is that, as long as the short circuit or other

Digitized by Google

cause of abnormal current exists, the switch cannot be closed. This is effected as follows: On attempting to close the switch the carbon contacts are first made. This energises the electro-magnet, which attracts its armature, producing a lock of such a kind that the main switch cannot be closed. The Helios Company also show a form of resistance very suited for tramway use. In this, flat wires or ribbons are coiled up with asbestos paper spirally, the whole resembling in appearance coils of magnesium wire as supplied to the trade. Being arranged in vertical planes these resistances have an excellent cooling surface.

Messrs. Witting Bros., representing Electricité et Hydraulique, of Charleroi and Jeumont, show some car constructions and slung motors of an ordinary type. Their principal electrical speciality, however, has no reference to tramway practice. It is an alternating-current motor of special construction, for which it is claimed that it will start with only twice the normal current. The field has an extra winding, which is thrown out of phase with the ordinary winding by being connected through a self-induction coil. The armature resembles a three-phase rotor, with the windings connected through a resistance. When the motor has got up speed the extra winding of the field or stator is cut out, and the armature coils are short circuited. Messrs. Witting also exhibit a rather interesting lightning arrester. The trolley line is connected through a carbon resistance to a vertical iron rod running inside the upper of two serrated carbon blocks, forming the spark-gap—the lower carbon block being earthed. As the line current tends to keep up any arc formed across the spark-gap, a solenoid is connected in series with it. This is, of course, impervious to lightning, but when energised by the line current following the arc, lifts the iron rod and breaks the circuit.

Accumulators are represented by the Electrical Power Storage and Chloride Companies. The latter exhibit a type of cell supplied by them for the Bradford Corporation trams. The Electrical Power Storage Company show types of their batteries with the "K" type of positive. At this stand is also a small 500-volt battery for use on tramways, on what may be called the Dresden system, namely, a system of running from trolley wire outside the town, with accumulators charging at constant voltage and then running through the towns from the cells.

MUNICIPAL ELECTRICAL ASSOCIATION.

(*Continued from page 325.*)

Thursday, June 21st.

The Association met in the same building as on the previous day. The chief event of the morning's proceedings was a debate on electric motors, principally on the relative merits of single-phase, polyphase and continuous-current motors. A Paper was first read by Mr. T. P. Wilmshurst, of Derby, on "Power Supplied by Single-Phase Motors." This was followed by a Paper by Mr. C. A. L. Prussman, of Doncaster, on "Maintenance of Motors on Hire from an Electricity Works." Mr. Wilmshurst's Paper commenced with a general discussion of the advantages of alternate-current working and passed in review the various objections which are raised by opposing sides in regard to alternate currents versus continuous current. In the latter part of the Paper he discussed the results already obtained with alternate-current single-phase motors and described what has been accomplished in this direction at Derby, where there is a single-phase supply at a frequency of 40 ∽. The debate was opened by Mr. Ferranti, who plunged into the fray as the undoubted champion of the single-phase motor, as opposed on the one hand to the continuous-current and on the other hand to the polyphase motor. The single-phase motor was the coming thing and the only drawback to its use at present was the absence of a satisfactory condenser by which to split up the single phase supplied into the two phases requisite for starting the motor. Mr. Ferranti knew of a condenser which had been working satisfactorily for 4½ years and which would shortly be on the market. Mr. Fedden, of Sheffield, was inclined to view the whole subject as a "fairy tale" and could scarcely believe that the advocates of single-phase motors for serious work were not romancing. Mr. Chamen, of Glasgow, congratulated himself and all continuous-current men on being free from the troubles of alternate-current supply. In an interesting speech Mr. Langlon-Davies mentioned several merits and demerits of the single-phase motor. He particularly emphasised the importance of wave form in regard to the satisfactoriness of alternate-current motor working. The most objectionable wave form was the double-peaked wave. Mr. Quin gave some account of alternating-current work at Blackpool, and said that, owing to the number of different types of alternators there, the wave form was not constant for more than a few seconds at a time. Mr. Esson entirely disagreed with Mr. Ferranti with regard to the merits of the single-phase motor. He advised all alternate-current station engineers to have their alternators wound for polyphase working, an operation which simply consisted, he said, in putting additional coils into the empty holes provided in the stampings of the alternator armatures. The cost of this addition would only be 5 per cent. on the cost of the machine. He doubted whether there was a good condenser on the market, and whether anyone could supply such. At the close of this discussion Mr. R. C. Quin, of Blackpool, read a Paper on "Combined Management of Tramways and Lighting Departments." The Paper advocated the combination, under one chief electrical engineer, of all the technical work and management of municipal electric tramways and supply. A number of municipal electrical engineers supported the author of the Paper, and this view was also adopted by not a few chairmen of committees who spoke. Baillie Willock, of Glasgow, gave an interesting account of the circumstances which led to the separation of the tramways and lighting departments at Glasgow. The proceedings terminated with a discussion on a Paper by Mr. H. L. P. Boot, of Tunbridge Wells, on "The Reduction of Light Load Losses in Alternate Supply Works." Owing to the lateness of the hour, however, this Paper was but little discussed. In the afternoon the Association enjoyed the garden party given by the mayor of Huddersfield at Beaumont Park; and in the evening it celebrated its annual dinner at the Town Hall.

Friday, June 22nd.

Before commencing the business of the day the Association travelled to Leeds and assembled at the Albert Hall, where a number of Papers were read. The first discussion was on a couple of Papers on "The Distribution of Electricity in Scattered Areas," by Mr. L. Andrews, of Hastings, and Mr. G. Wilkinson, of Harrogate. It would, however, be useless to attempt to give an abstract of this discussion until our readers have had an opportunity of seeing the Papers, and we therefore refer them to the abstract of the discussion which we shall publish shortly with the Papers. Mr. C. H. Wordingham's Paper on "Maintaining Certain Portions of Electrical Distribution Systems at Earth Potential" gave rise to a short but useful discussion, partly on the earthing of the middle wire of three-wire electricity supply systems and partly on the earthing of the return conductor of tramway systems. The general opinion seemed to be in favour of earthing the middle wire and the return of high-pressure feeders in electricity supply systems. With regard to the return conductor for tramways, the dangers of electrolysis, in the view of most speakers, would be obviated by carefully bonding the neighbouring gas and water pipes to the return conductor. The next Paper was by Mr. A. E. Le Rossignol, of Newcastle-on-Tyne, and gave his impressions of the present American tramway practice. Mr. Le Rossignol has recently visited the United States with a view to studying, principally, the trolley system. He does not appear to be favourably disposed towards the slotted-conduit system, regarding its heavy expense as too serious a drawback. In the discussion several speakers gave accounts of their travels over electric tramways in the United States, and the relative advantages of the trolley and rival systems were briefly referred to. One important point emphasised was the great part played by the trolley system in

Digitized by Google

solving the housing problem for the working classes. Rapid transit and low fares enable a considerable proportion of the town population to live several miles from the centre of the town, this tending greatly to increase the healthfulness of town life. The concluding Paper on "The Protection of Telegraph and Telephone Wires," in connection with overhead traction, was read by Mr. R. C. Quin, of Blackpool. Mr. Quin advocated placing telegraph and telephone wires underground, as the best solution of this difficulty; but inasmuch as the Postmaster-General has refused to adopt this view, Mr. Quin has drawn up a number of recommendations with regard to guard wires. These, if carried out, would prevent accidents from the breakage of wires crossing live trolley wires. In a short discussion which ensued, it was suggested by one speaker that the guard wires should be provided with a switch so that they might be disconnected from earth when men were engaged in repairing the line. Mr. Quin, however, pointed out that this switch was superfluous, as, though it might protect the men from injury due to contact with guard wires, it would not protect them from injury through touching the brackets and poles. These brackets, of course, could not be switched off from earth. In the afternoon the Association visited the various electricity works in Leeds, including the tramway power station, trolley lines and municipal electricity works.

Saturday, June 23rd.

The business meeting of the Association was held at the Technical College, Huddersfield. The report of the Council showed that good progress had been made by the Association during the past year, and many subjects of interest to electrical engineers had been brought before the Council for their consideration. It was resolved that the Convention of 1901 be held in Glasgow, and the following is a list of the Council for next year:—

President.
W. A. CHAMEN, Glasgow.

Vice-Presidents.
F. A. Newington, Edinburgh; H. Dickinson, Leeds.

Past Presidents.
C. H. Wordingham, Manchester; H. Faraday Proctor, Bristol; A. B. Mountain, Huddersfield.

Council.

L. Andrews, Hastings.	Bailie Maclay, Glasgow.
A. S. Barnard, Hull.	R. C. Quin, Blackpool.
Ald. F. Calvert, Huddersfield.	J. F. C. Snell, Sunderland.
J. E. Edgcome, Kingston-on-Thames.	Councillor J. P. Smith, Barrow.
A. Ellis, Bolton.	T. P. Wilmshurst, Derby.

Hon. Solicitor.—Ald. G. Pearson, Bristol.

Hon. Treasurer.—J. H. Rider, Corporation Electricity Works, Plymouth.

Hon. Sec.—E. T. Ruthven Murray, 21, Acton-lane, Harlesden, N.W.

The following gentlemen were appointed to control the benevolent fund:—

C. H. Wordingham, Manchester.	H. Faraday Proctor, Bristol.
S. E. Fedden, Sheffield.	C. D. Taite, Southport.

The president announced that this fund now amounted to a sum approaching £50, and he solicited further subscriptions. Hearty votes of thanks were accorded to the Huddersfield Corporation, Bradford Corporation, the Lord Mayor of Leeds and Leeds Corporation, the president and members of the Technical College, Huddersfield, and the president and members of the Borough Club and Huddersfield Club for their kindness and hospitality during the convention. Bailie J. Willock proposed and Mr. W. A. Chamen seconded a hearty vote of thanks to the president (Mr. A. B. Mountain) for the way in which he had presided over the meetings, and for the work he had done for the Association during the past year.

After the business meeting a number of members and friends visited the Harrogate electricity works upon the invitation of Messrs. J. & H. McLaren, of Leeds. The members were taken from the railway station to the electricity works in conveyances, and after the inspection had been made they returned to the Crown Hotel, where Messrs. McLaren had provided light refreshments. After the usual toasts and votes of thanks to Messrs. McLaren and the Harrogate Corporation, the Montpelier Garden and Baths were visited, which concluded a very instructive and enjoyable convention.

MEANS FOR STIMULATING THE DEMAND FOR ELECTRICAL ENERGY.

The following is an abstract of the discussion on the two Papers on this subject read at the convention of the Municipal Electrical Association at Huddersfield, last week, by Ald. W. Potter, of Taunton, and Mr. H. C. Bishop, of Wigan. These Papers were reprinted in our issue last week, page 830:—

Mr. H. FARADAY PROCTOR (Bristol) felt that "How to Stimulate the Rapid Extension of Buildings and Plant" would have been a more suitable subject for Bristol. Many suggestions have been made for making the electric light more popular, and he had been surprised that more attention had not been paid to stimulating the demand. He believed that the 3½-watt lamp was commonly used, but it was far from being the most economical. Where 5d. was charged, the 2-watt lamp would be nearer the mark. In the case of very small installations he thought one of the means for reducing the cost of connecting these should be to supply from a house-to-house system, by cutting the main in one place for three or four houses, and running an insulated wire inside the houses. He thought it was a mistake to lay down the mains in those streets only where the best shops were, as the best class of consumer was to be found in the poorer districts, where the hours of lighting were usually longer. He thought the so-called "free-wiring" was on a wrong basis from the point of view of the suppliers of electricity, since the long-hour consumer was the man who was least encouraged; the most fair principle seemed to be a simple hire with option to purchase. If a man was tenant on a short lease he did not want to buy out the installation at any time. With regard to public street lighting he thought it was better to charge a fixed sum for the current used, and in addition to this a certain sum for attendance. He considered the use of a battery for the 1½-hour consumer was a good scheme, but he thought 6 per cent. was too low for the permanent maintenance of a battery. Further, in working out Mr. Bishop's figures, he found that the motor generator would have to run "30" hours per day to charge the battery; this meant, of course, that the battery allowed for was not large enough.

Mr. T. P. WILMSHURST (Derby) said they all agreed with Mr. Potter that low cost was an important factor in stimulating the demand. The question of the cost of the installation was one which introduced a good deal of contentious matter. Although undoubtedly it is necessary to assist a certain class of consumer, the discussion would principally arise upon how that should be done. He did not agree with the system of the Free Wiring Company, which adds a certain amount to the bill of the consumer for current; and he still less agreed with the system which Ald. Potter said they had in use at Taunton. He considered it was better to have a uniform price and charge all alike. The two systems mentioned were antagonistic in principle to the demand indicator. As an illustration, in a town where the initial price is high, say 7d. or 8d. per unit, and the secondary price is low, under Mr. Potter's system a long-hour consumer who might get his current at an average of 3d. or 3½d. per unit would have to pay 7d. It may certainly work well in Taunton where the price is 6d. and 3½d., but even then he would not be surprised in the case of long-hour consumers if they did not pay more than 1d. extra. It was good policy to lay mains in likely districts. He was surprised that Ald. Potter had not mentioned the question of street lighting because this went hand and glove with the question of extending the mains. Wherever mains were laid they should, if possible, extend the street lighting. The advantages of this were two-fold; it was an outward sign that the electricity mains passed the door. Further, the Electric Lighting committee would then be assured of one good consumer, and it made it worth while to extend the mains into the district. In Derby they had permission from the Highways committee wherever they laid mains to convert the gas lamps to electric lamps under the sole condition that the cost for lighting should not exceed that previously paid for gas. He was very strongly in favour of hiring out motors. In Derby they were doing this, and in a very short time they had succeeded in getting on to the mains about 250 H.P. in motors.

Mr. F. A. NEWINGTON (Edinburgh) said that in Edinburgh they did not require the demand to be stimulated as they were connecting up lamps quicker than they conveniently could. He was strongly in favour of hiring out motors and in Edinburgh they were just considering this subject. There was one matter which he thought would be very useful, if it could be obtained, and that was a two-rate meter, so that they might charge a low rate during the daytime and a higher rate at night.

Mr. G. H. NISBETT (Prescot) thought corporations should be more ready to adopt the methods which have been adopted at Taunton as the results obtained there spoke well for the system of free wiring. He pleaded guilty to having circulated the words "Free Wiring," which were undoubtedly misleading; perhaps it would be better to call it "Free-of-initial-expense-Wiring," then the customers would understand it better. The advantage of the so-called system of free wiring lay in the fact that the tenant really pays a rent for it, and no tenant who was paying rent for a house desired to instal the wiring at his own cost when it would become the property of the landlord.

Ald. RICHARDS (Bedford) said he thought they should not charge an extra price for street lighting, but should give the ratepayers an advantage in this respect and charge a low figure, as this was the only electric lighting which some of them were permitted to enjoy. At Bedford they had reduced their price from 6d. to 5d. per unit, which had been the means of stimulating the demand very considerably.

Ald. BRUCE (Sunderland) thought that if the wiring had to be done by any other than private enterprise it should be done by the Corpo-

Digitized by Google

ration themselves. He considered the best way for free wiring was not to charge so much per unit for the hire, but to charge a certain percentage upon the capital outlay on the wiring. He said they would have to deal with customers in two different ways: They would have to give them an opportunity to use the maximum demand system, and also encourage them in some way to put the lamps into all the rooms of a house.

Councillor BRIANT (Brighton) spoke of the advantages of the maximum demand system for encouraging consumers to use their lights a long number of hours. At Brighton they were charging an initial price of 7d. per unit and 1d. afterwards to encourage a long hour demand. He thought they should charge the same for street lighting as for private lighting upon this system which they did at Brighton, and as a result they were able to give three times the amount of light for the same expenditure. It would be interesting to know where and to what extent electrical energy had been adopted for heating purposes.

Mr. J. E. EDGCOME (Kingston-on-Thames) said that at Kingston-on-Thames they had promoted a bill in Parliament for powers to borrow £10,000 to carry out wiring work, and this had been passed without any trouble. When they obtained these powers it rested with the Committee to decide in what way they should use them. Should they hand the work over to the Free Wiring Company, or should the Corporation do the work themselves? It was very difficult in a small town like Kingston to keep the necessary staff continually going on this work, so they had decided to ask for information from other towns as to what they had done in this respect. From the replies he had received he was struck with the large number of towns which were doing nothing at all.

Mr. W. A. CHAMEN (Glasgow) asked the question whether it was necessary for corporations to do this work at all—*i.e.*, wiring work. He thought it would be much better if done by a company from whom the consumer could hire the wiring, motors, &c., just as one hired a bicycle, piano, &c. Nothing had been done, however, in this respect at Glasgow, as the demand had grown more rapidly than they had been able to meet. He thought, however, in small towns some system of free wiring was necessary. With reference to the method of charging for electrical energy, Mr. Newington had mentioned a two-rate meter, which seemed to be the nearest perfection because the maximum demand indicator does not give the time when the maximum demand occurs. He asked if the matter, however, could not be simplified by charging an all-round price to domestic consumers, and by this class he meant all those premises in which persons slept at night. For motive power purposes the charge in Glasgow was 1½d. per unit to those using the supply 5 hours per day.

Ald. POTTER, in reply, said that he agreed that the introduction of the Free Wiring Company into a town stimulated the demand, as the company canvassed the district thoroughly and made the installation work grow. With reference to street lighting, the policy adopted at Taunton was wherever they laid the electric supply mains to turn out the gas lights and put on incandescent electric lamps, using as far as possible the old lamp posts. He did not advocate a high rate of charge for street lighting, and his contention also was that they should not charge the ratepayers less for the street lighting than it actually cost. They had introduced slot meters at Taunton, and he was assured by their engineer that they were a great success. For heating purposes they had about 15 radiators on the mains and these also gave great satisfaction.

Mr. H. C. BISHOP, in reply, said that as the time was limited he would make his reply in the *Proceedings* of the Association.

ELECTRIC ROAD LOCOMOTION.*

Introductory.—There can be no doubt that with the rapid means for communication of ideas by telegraph and telephone, and of passengers and goods by means of the railway, the general want is felt of a more speedy means of transport by road. The great improvements which are needed in our road traffic have been set forth by Major R. E. B. Crompton, R.E., at present in South Africa, and one of our old members, in a Paper read by him before the Automobile Club, in which he clearly shows the vast and beneficial changes that the general introduction of the motor vehicle would effect in the relief and expedition of traffic in our cities, and especially in the metropolis.

Nor must the hygienic considerations be overlooked. This subject has been ably dealt with by Mr. Shrapnell Smith, Honorary Secretary of the Liverpool Self-Propelled Traffic Association (to whom the author is indebted for valuable assistance in many points dealt with in this Paper, and particularly in connection with the final section). In his Paper, read before the Congress of the Sanitary Institute at Birmingham in 1898, he points out that with motor vehicles, not only will our streets be less offensive, especially in summer weather, but exposed food stuffs will less frequently afford a *nidus* for organisms conveyed by disseminated particles from the roads; further, that the disintegrating effect of the horses' hoofs, which accounts for most of the dust of summer and the pasty slime of winter, will be to a great extent obviated. The sanitary advantages of the motor vehicle have also been recognised and strongly urged by many medical officers of health and surveyors to municipal and urban councils. This shows, then, what forces are at work urging us, both for light and heavy traffic, in the direction of utilising more efficiently and with mechanical power the 100,000 miles of road which we possess in this country.

* Extract from a Paper on "Road Locomotion." Read by Prof. H. S. Hele-Shaw, F.R.S., before the Institution of Mechanical Engineers.

Electricity.—The whole problem of the use of electricity in motor vehicles is determined by the life and capacity of the battery, and the merits of any accumulator should really be judged to a great extent by the condition of its batteries after six months' daily use in a motor vehicle. The fact is that the sudden heavy discharges, so often taking place with a motor vehicle, expand the grids and release paste, which is washed out by the movement of the surrounding acid, and these detached particles cause internal short-circuiting by remaining in suspension between the plates. If a cell is short of "acid room," excessive heating expands the grids to such an extent that they never contract sufficiently to make good their connection with the remaining paste. Moreover, splashes of acid are the cause of much more loss than is usually suspected. Again, the practice of grouping cells in parallel is open to the serious objection that if a cell on one side becomes dead or is reversed, those on the other expend energy in re-establishing equilibrium. English, French, and American tests prove that after six months' running, even under the most careful supervision, practically all secondary cells must have the positive plates re-pasted or renewed at a cost not below one-fifth of the original outlay, while in many cases as commonly used they are practically worthless at the end of this period or even sooner. So long as a range of 40 miles per charge, at speeds not exceeding 10 miles per hour, meets the requirements of an automobilist, electricity, at a cost of not more than 2d. per B.T.U., is at least on a par with steam or oil even for heavy traffic. Where these limits are exceeded, electricity is inadmissible. Distances greater than 40 miles, and speeds greater than 10 miles an hour, involve prohibitive dead-weight and excessive discharge rates.

It is a pity that no electrical motor vehicles for heavy traffic have yet been brought to the practical stage, as this is to be regretted for several reasons. The ease with which each of the four wheels of a lorry can be driven is of particular importance in respect of available propulsive effort, whilst the motors and batteries can readily be disposed so as to leave the entire platform free for merchandise. The weight of accumulators is not included in the legal tare of three tons, and the slower rates of speed demanded in this class of traffic should permit of a low ratio of battery weight to total moving weight. Experience has shown that, with a total moving weight of one ton, one-third each being batteries, vehicle and load, the effective distance is about 43 miles at a speed of 8 miles per hour, and only about 24 miles at a speed of 15 miles per hour on average roads.

It must be borne in mind that the cells deteriorate sadly when used for high speeds; nevertheless, results have been attained on a motor vehicle by electricity which surpass anything by any other kind of motive power. An account of these results has been given by the Marquis de Chasseloup-Laubat in the *North American Review* for September, 1899, which it is interesting to quote. "On Jan. 27, 1899, Jenatzy, mounting a carriage not specially constructed for great speed, left the starting point (a straight, level road near Paris), and covered 2 kilometres (1¼ miles) in 1min. 41⅕sec.; the first kilometre (⅝ths mile) with a standing start in 57sec.—that is, at the rate of 63·166 kilometres an hour (39·2 miles), and the second kilometre with a running start in 44⅘sec., that is, at the rate of 80·357 kilometres (50 miles) an hour. On March 4, 1899, Count de Chasseloup-Laubat, on a Jantard carriage, not specially built for this style of test, but with certain most important modifications, such as running the front and rear of the carriage into sharp points, so as to offer least resistance to air, covered the same course of 2 kilometres (1¼ miles) in 1min. 27⅗sec., the first kilometre with a standing start in 48⅗sec., or at the rate of 75 kilometres (46⅝ miles) an hour, and the second kilometre with a running start in 38⅘sec., or at the rate of 92·783 kilometres (57⅝ miles) an hour. Finally, on April 29, 1899, Jenatzy, riding a carriage specially built to break all records, and which has the shape of a large cigar mounted on four small wheels, made the 2 kilometres (1¼ miles) in 1min. 21⅕sec., the first kilometre with a standing start in 47⅘sec., and the second kilometre with a running start in 34sec., or 105·852 kilometres (65⅘ miles) an hour. The extraordinary nature of these results lies not so much in the fact of a high speed of 65 miles an hour by a motor vehicle, but in the fact that starting from rest the average speed for the first kilometre was 46¼ miles an hour. It is safe to say that no locomotive has ever achieved this result, that is, a distance of a mile covered from rest in less than 80sec., and those who witnessed the trials say that the start of the electrical carriages under these conditions left the same kind of impression on the observers as the start of a rocket. There is little doubt that these results could be beaten if the consequent expense were to be faced, but, according to report, the batteries were themselves practically destroyed in the run, and at any rate the contesting vehicles were not only towed out to the scene of the trial, but towed home again afterwards, and the trial, though interesting as showing the possibilities and use of electricity, must not at all be taken as giving results which could be of use for practical purposes."

Gearing or Transmission.—The ordinary modes of transmitting power, viz., by friction gearing, toothed-wheels, belts and chains, have been specially adapted and employed for transmitting the power

Digitized by Google

from the motor to the driving wheels of a motor vehicle. The requirements for this particular purpose are in many respects of a special character, and the author had collected material for a special section of the Paper devoted to this subject. It has become evident, however, that it would be impossible to treat the question in a satisfactory manner within the limits of this Paper, and the subject well deserves a special Paper before the Institution. Take for instance the transmission of power by chain-gearing. This mode of transmission, from being in a very crude state a few years ago, has received so much attention that chain-gearing is as efficient, if not more so, than any other mode of transmitting power; whereas the wearing of the links of the chain, which as it occurs gives so much trouble and annoyance, has been met by the special provision of large bearing surfaces which are hardened, so that the mechanism of the chain-gear may be said now to compare favourably with the other working parts of the engine, such as cross-head pins and main bearings. The efficient lubrication of the chain is a matter of the greatest importance and difficulty. The grease chiefly requires to be *inside* the joints, and Major R. E. Crompton showed the author a most ingenious way of effecting this which he has most successfully employed with bicycle chains. He places the chain in a bath of melted grease, in which graphite is mixed. The air being expelled from the joints of the chain by the heat, the mixture naturally finds it way between the pins and rollers, and forms a complete internal solid lubricant, when the whole is allowed to cool together.

The Renold chain, which is largely used in heavy motor traffic, is a beautiful invention which meets in a most ingenious manner the change of alteration of pitch due to wear, and the latest improvements in this chain are also designed to obviate as far as possible the wear upon the pin itself, and reduce it to a minimum.

Again, one special feature of the oil engine is the necessity for change of speed gearing of some form or other, and this has led to a large number of arrangements of speed gearing which of themselves are worthy of detailed consideration. Besides the arrangements for changing the speed ratio by means of combination of toothed wheels are inventions such as the expanding and contracting pulley of Mr. Lucas, the arrangement for altering the throw of an eccentric through which the power is transmitted, such as in the invention of Mr. Newton, and last, but not least, the most ingenious hydraulic variable speed gear of Mr. Hall. These inventions are all in actual operation with apparent success, but unless actually examined they could not really be understood, except by means of drawings with detailed descriptions. It is obvious therefore that this part of the subject must be left for future treatment.

PHYSICAL SOCIETY.

At an ordinary meeting held on June 22, 1900, Mr. T. H. Blakesley, vice-president, in the chair, a Paper entitled

"Notes on Gas Thermometry,"

by Dr. P. CHAPPUIS, was read by Dr. Harker. The author, having been led to recognise that hydrogen could not be used as a thermometric substance at high temperatures on account of its action on the walls of the glass reservoirs, has had recourse to a constant volume nitrogen thermometer, with an initial pressure slightly under 800mm. The value of the coefficient of expansion of nitrogen at constant volume is variable, diminishing up to 80°C. and then increasing slightly. In fact, nitrogen at 100°C. behaves like hydrogen at the ordinary temperatures, its compressibility being less than that required by Boyle's law. A table of corrections was therefore prepared. The readings of the constant-volume nitrogen thermometer are too low, but the corrections are small, amounting to about 0·04°C. at the temperature of boiling sulphur. The mean result of the author's experiments for the boiling point of sulphur is 445·2deg. under a pressure of 760mm. The Callendar and Griffiths' result obtained with a constant-pressure air thermometer is 444·53deg. The difference is attributed to the joint action of several causes: (1) The corrections for a constant-pressure thermometer are about double those of a constant-volume instrument. This correction applied to Callendar and Griffiths' result would raise it about 0·1deg. (2) Callendar and Griffiths have used a value for the gas constant which is larger than that obtained by more recent experiments. Adopting the latter value, the boiling point would be raised to 445deg. (3) The divergence may be due to the expansion of the reservoir. The most accurate way of determining this is by the interference method of Fizeau. This method is used with small pieces of the material, and the author has employed it to determine the coefficient of expansion between 0deg. and 100deg. Extrapolation to 450deg. might cause errors. The linear expansion has recently been determined by Bedford between 0deg. and 840deg. by a comparator method. The homogeneity of porcelain is doubtful, especially when glazed, and the great differences occurring between the expansions obtained from the above methods is attributed to the change in form of the tube in Bedford's experiments, brought about by unequal thickness and want of homogeneity and consequent unequal expansion. The author therefore adheres to his value of the boiling point obtained from the expansion by the Fizeau method, whilst recognising the uncertainty attaching to the application of the coefficient of expansion of the reservoir over an interval four times as great as that over which it was determined.

A Paper on

"A Comparison of Impure Platinum Thermometers,"

by Mr. H. M. TORY, was read by Prof. Callendar. The object of this Paper is to investigate the probable order of accuracy attainable in the determination of high temperatures by the use of ordinary commercial specimens of platinum wire. Five wires were compared—from 400°C. to 1,000°C. The fundamental coefficients of the wires varied within 40 per cent. of the maximum value, but the temperatures observed by them when calculated on the platinum scale by means of the ordinary simple formula, did not differ by more than 9deg. at 1,000°C. Each wire was directly compared with a pure standard wire, the two being wound side by side in the same tube. Curves have been drawn with the platinum temperatures of the standard wire as abscissæ, and the differences between the temperatures indicated by the two wires compared as ordinates. These curves are all straight lines within the limits of observation, and hence the determination of two constants is sufficient to enable us to compare an impure platinum thermometer with the standard, and therefore with the scale of the gas thermometer. The two constants can at once be obtained from observations at the boiling point of sulphur and the freezing point of silver, and thus a practical thermometric scale can be established, which between 0deg. and 1,000deg. never differs by more than two or three degrees from the gas scale.

Prof. H. L. CALLENDAR said he was unable to agree with the correction to his observations suggested by M. P. Chappuis. He considered that the uncertainty in the coefficient of expansion of the gas was due to uncertain changes in the volume of the bulb, and to uncertainty in the coefficient of expansion of mercury. The fundamental coefficient of mercury was 0·00018153 according to Regnault, 0·00018216 according to the later reduction of Broch, and 0·00018256 according to experiments by Chappuis with a hard glass bulb. It made a difference of no less than 4 per cent. in the fundamental coefficient of expansion of the glass, according as the original results of Regnault, or the value found by Chappuis, assuming the linear expansion of the glass, were adopted. The importance of the changes in the volume of the bulb had been fully pointed out, and a method of taking approximate account of these changes had been explained in the Paper on the boiling point of sulphur in 1890. Unfortunately, the glass employed was rather soft, and the changes of volume which occurred were too great to permit of the most accurate determination of the coefficient. The boiling point when corrected for the smaller expansion of the bulb, came out lower than 444·53deg. With regard to porcelain, Prof. Callendar did not consider it a good material on account of the glaze. He did not think that the average coefficient of a tube or bulb over a large range of temperature could be inferred from a small and possibly a symmetric specimen. The results might be less inconsistent in the case of homogeneous and well-annealed metallic bulbs. The correction for the expansion of the bulb was, he believed, given by the expression $dt=(c+b\theta)\,t\,(t-100)$. He did not agree with M. P. Chappuis that the correction was independent of c, although the value of b was certainly most important at high temperatures. He also wished to take exception to the method adopted by Chappuis of calculating the correction of the nitrogen thermometer. According to Joule and Thomson, the correction should be greater, and according to other authorities it might be less. He hoped to discuss this in a future communication to the Society.

Mr. R. T. GLAZEBROOK said that, although he placed confidence in Chappius' formula for a definite piece of porcelain between certain temperatures, he thought further and careful work was necessary before fixing on a formula for ordinary use.

Prof. CARHART said he would like to see a comparison made between the results of experiments with gas thermometers and those with platinum and platinum-rhodium couples.

Mr. ROSE-INNES expressed his interest in the behaviour of nitrogen, at about 100°C, as mentioned in M. Chappuis' Paper.

Dr. LEHFELDT said the peculiarities of the nitrogen scale between 70deg. and 80deg. might be explained by the reversal of the properties of nitrogen between 0deg. and 100deg.

A Paper on

"The Law of Cailletet and Mathias and the Critical Density."

was read by Prof. S. YOUNG. The law of Cailletet and Mathias is very nearly, though in most cases not absolutely, true. It appears to be only strictly true when the ratio of the actual to the theoretical density at the critical point has the normal value 3·77. The curvature of the "diameter" is generally smaller the nearer the ratio approaches its normal value. The curvature is in nearly every case in opposite directions according as this ratio is greater or less than 3·77. The curvature is generally so slight that the critical density may be calculated from the mean densities of liquid and saturated vapour at temperatures from about the boiling point to within a few degrees of the critical point with an error generally not exceeding 0·1 per cent. If, however, the critical density is calculated from the mean densities at low temperatures the error may be considerable; in the case of normal decane it is between 5 per cent. and 6 per cent.

Digitized by Google

The law does not, as a rule, hold good at all for substances the molecules of which differ in complexity in the gaseous and liquid states.

Mr. ROSE-INNES said that in his Paper the author had used the generalisations of Van der Waals, although the author himself had shown that they were not strictly true.

Prof. S. YOUNG said that the generalisations held in some cases, although they did not in others. In all cases they were approximately true, and it was therefore advisable to use them and study the results as far as possible.

The Society then adjourned until next October.

BATTERY MOTOR CARS.

In No. 9 of the *Centralblatt für Accumulatoren und Elementenkunde* Herr P. Weber discusses some of the questions which have arisen in connection with the arrangement and use of accumulators for traction purposes, with the view of obtaining a more uniform practice in these respects, such as has already been obtained in regard to the voltage (110 volts) to be employed. Much has been written and said concerning the best number of cells to employ, but this is a matter of little importance, since it depends on the make of cell used, and has nothing to do with the arrangement and coupling up of the battery, which Herr Weber considers a point whose importance has been under estimated. It is often stated that the disadvantages of working with a battery divided into two halves which can be coupled in parallel outweigh the advantages of the arrangement, and that a pure series method of connection is to be preferred. But in the latter case a loss of energy results from the resistance which has to be inserted to reduce the voltage of the battery, which, on the other hand, can be instantly reduced by one-half by connecting the two portions of the battery in parallel. It is not advisable, however, to subdivide the battery further. The chief point which has to be considered in determining the arrangement of a battery is whether it will have to drive one or two motors. In the latter case two speeds are given by connecting the motors in series or in parallel. The number of speeds which the battery should furnish is another matter concerning which there is much diversity of opinion, and in which a free discussion of the subject might lead to greater uniformity of practice. In general, it is sufficient if the regulating switch gives four to five speeds, has two brake positions, and will reverse the car. There are some regulators so constructed that the reversal of the movement of the car can only be effected by a special switch, but such an arrangement is scarcely practical. The best form of regulator is one in which the reversal position follows the brake position, so that the car is slowed down before its motion is reversed. In deciding on the size of the battery it must always be remembered that cells never give as good results when employed in traction work as they do when tested in the laboratory. The author tested some motor-car cells for the Berlin Accumulatoren und Elektricitätsgesellschaft on a specially-constructed shaking apparatus, so as to reproduce practical working conditions, and found that the cells when thus shaken had a smaller capacity than they had when at rest, although it might have been thought that the reverse would have been the case, on account of the better circulation of the acid. The jarrings, however, to which the cells were subjected were more violent than those which would be experienced even on a bad road, as it was desired to test the solidity of the construction of the cells. The cause of the extraordinary diminution in capacity which cells often exhibit when employed on traction work, as compared to their behaviour in the laboratory, is principally due to the temporary severe strains to which they are subjected, and often amount to from one and a-half to two and a-half times the normal working load. The reserve of capacity which must be provided will be determined from a consideration of the working conditions on the road which the car will usually have to travel. In general, an excess of capacity of about 40 per cent. will not be too much to allow in the battery, and firms that build electric cars must take this factor into consideration, in addition to considering the weight, dimension and price, if these cars are be depended on.

ELECTRICITY WORKS ACCOUNTS.

Hammersmith Vestry Electric Supply Works.

The year of working to March 25th last was the second completed by the Hammersmith Vestry electric supply undertaking. The accounts show excellent results and progress.

During the year the lamp connections increased from the equivalent of 21,825 8 c.p. lamps to 30,131, or 38 per cent. Still better is the improvement in the output of from 517,629 units sold to 891,301, or over 72 per cent. Not only this, but the character of the load was much more favourable to low costs, in that while the load factor of 1898-9 was 11·8 per cent.—even thus above the average—this factor rose last year to 14·5 per cent.

Turning to the revenue and expenditure figures, a general and material reduction in the costs has enabled the working profit to be well maintained notwithstanding the reduction in the average total revenue per unit of from 4·28d. to 3·68d., or 14 per cent. The costs column shows figures which may fairly be said to be uniformly representative of good practice under similar conditions of output and load factor. Allowance has, of course, to be made for the high prices which have been the rule rather than the exception in the coal trade during the last year, and the figure of 0·787d. per unit for fuel may therefore be passed as quite satisfactory in the circumstances.

It will be seen that the plant capacity at the station has been increased to 1,300 kw., and that the capital expenditure for the year was £32,078. From the report of the Chairman of the Lighting committee, it appears that a large proportion of this expenditure was only lately made, and that the average capital during the year was probably about £30,000, to which the year's working profit represents about 73·7 per cent.

Richmond (Surrey) Electric Light & Power Co.

Although the accounts of the working of this undertaking during 1899 show that the costs have slightly increased, the results are most commendable in view of the output of only 191,084 units sold, and a load factor of 8·9 per cent.

The increased expenditure is limited to the two items of fuel and distribution wages. It is satisfactory to find that in spite of increases in the rents, rates and taxes, the management and property charges have been reduced, since this collective item stood somewhat high in 1898. Probably the rents, rates and taxes will always continue to militate against any very favourable figures being obtained in this department.

The lamp connections and the output continue to make but slow advances. Last year the former showed an increase of only 13·7 per cent., and the latter little more than 15 per cent. This slow progress was inevitable while the tariff stood as it did, and exacted an aggregate revenue of nearly 7·17d. per unit sold. However, we are glad to learn that a substantial reduction, not only in the charge for current, but also in the meter rentals, was decided upon to take effect after March 31 last. With the favourable costs which have lately been attained at Richmond, such an alteration in the tariff cannot fail to be of benefit by increasing the business done.

In the following table are repeated the more interesting figures of the last five years:—

Year.	No. of consumers.	Lamp connections.	Units sold.	Plant capacity.	Max. supply demanded. Kw.	Total revenue per unit.	Total costs per unit.
1895	116	5,486	80,456	290	107	7·25d.*	7·08d.
1896	143	7,125	97,044	290	135	7·89d.	5·02d.
1897	167	9,512	138,916	290	185	7·72d.	3·86d.
1898	215	12,538	166,087	290	213	7·37d.	3·22d.
1899	...	14,256	191,084	590	244	7·17d.	3·27d.

The Electrician.

The Oldest Electrical Journal (established as a weekly Journal 1861–1878

Published every Friday, Price Sixpence; Post Free, Sixpence-Halfpenny.
Editorial Publishing and Printing Offices,

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.

Telephone: 949 Holborn. *Telegrams:* "ELECTRICIAN NEWSPAPER LONDON."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed* "*Coutts and Co.*"

All Editorial letters to be addressed to THE EDITOR.

All letters for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer as evidence of good faith. No notice whatever is taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices, as above*

Subscription Rates.—The Rates for Subscriptions to "THE ELECTRICIAN" are as under:—

	YEAR	HALF-YEAR	QUARTER	
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.	Post free, payable in advance.
Postal Union	30s. 0d.	16s. 0d.	8s. 0d.	

New Volumes of "THE ELECTRICIAN" *commence in April and October.*

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.** *This statement is guaranteed.*

Advertisement Rates, &c., forwarded on application to the Publisher.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Office not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday. Wrapper Advertisements by Wednesday morning.*

OFFICIAL ANNOUNCEMENTS, AUCTIONS, *and* SMALL ADVERTISEMENTS *accepted up to* **6** *p.m. on Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of THE ELECTRICIAN" *Printing and Publishing Company, Limited. The well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works at present consists of—*

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. ELTON YOUNG, M.I.E.E. Price 10s. 6d., post free; abroad 11s.

THE STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By Messrs. H. K. C. FISHER and J. C. H. DARBY. Price 6s. net; abroad, 6s. 3d.

BIBLIOGRAPHY OF X-RAY LITERATURE AND RESEARCH. Edited by C. E. S. PHILLIPS. With an introduction on the history of Crookes Tube and Röntgen Ray work, and a chapter giving "Practical Hints" on the subject.

THE POTENTIOMETER AND ITS ADJUNCTS. By W. C. FISHER. Price 6s., post free.

LOCALISATION OF FAULTS IN ELECTRIC LIGHT MAINS. By F. C. RAPHAEL. Price 5s., post free.

MOTIVE POWER AND GEARING. By E. TREMLETT CARTER. Price 12s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. WILKINSON. Price 12s. 6d., post free.

ELECTRICAL LABORATORY NOTES AND FORMS (Elementary and Advanced). Arranged by Dr. J. A. FLEMING, M.A., F.R.S. Printed particulars on application.

ELECTROMAGNETIC THEORY. By OLIVER HEAVISIDE. Vol. I. Price 12s. 6d., post free 13s. Vol. II. Price 12s. 6d.; post free, 13s.

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING. VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. NEW EDITION. Price 12s. 6d., post free. VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. FLEMING, M.A., D.Sc., F.R.S. New Edition. 93 original illustrations, price 6s

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. EWING, M.A. New edition. Price 10s. 6d., post free.

ELECTRIC MOTIVE POWER. By A. T. SNELL. 10s. 6d. post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d.; post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. WEYMOUTH. Price 7s. 6d. post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By GILBERT S. RAM. Price 7s. 6d., post free.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. GEIPEL and H. M. KILGOUR. Price 7s. 6d. net, post free 7s. 9d., abroad 8s.; large-paper edition, 12s. 6d., post free. New edition in the press.

"THE ELECTRICIAN" PRIMERS. In Two Vols. Paper covers, 2s., post free 2s. 2d. each; strong cloth 2s. 6d., post free 2s. 9d. each. Single Primers 2d., post free 2½d.

WIRELESS TELEGRAPHY: SIGNALLING ACROSS SPACE WITHOUT WIRES BY ELECTRIC WAVES. By Dr. O. J. LODGE. New Edition. Price 5s. net.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING, ELECTRIC TRACTION, TELEGRAPHS, TELEPHONES, &c. A. C. CURTIS-HAYWARD, B.A. To January, 1900. Price 3s. 6d., post free.

CARBON MAKING FOR ALL ELECTRICAL PURPOSES. By FRANCIS JEHL. Price 10s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d., post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 3s. 6d., post free.

FULL CATALOGUE POST FREE ON APPLICATION.

"ELECTRICIAN" SERIES FORTHCOMING BOOKS.

THE ELECTRIC ARC.—By Mrs. AYRTON. This work is in the press, and will contain an historical sketch of the early experiments on the electric arc, as well as the important results of recent research.

PRIMARY BATTERIES.—A work on this subject will shortly be published bringing the theory and practice of the Primary Battery up to date. The book will be fully illustrated.

SECONDARY BATTERIES.—By E. J. WADE. Fully illustrated. The Author in this work will deal briefly with the theory and fully with the chemistry, design, construction and manufacture of secondary batteries or accumulators.

"THE ELECTRICIAN" WIREMAN'S POCKET-BOOK.—Edited by F. C. RAPHAEL. "The Electrician" Company will shortly publish a valuable pocket-book for the use of those engaged in wiring work, both external and internal.

THE TELEPHONE.—By DANE SINCLAIR and F. C. RAPHAEL.

SPECIAL NOTICE.

NOW READY.—Vol. XLIV. of "THE ELECTRICIAN" (960 pages), bound in strong cloth. Price 17s. 6d., post free 18s. 6d. Also ready, Cases for binding. Price 2s., by post 2s. 3d.

A complete set of "THE ELECTRICIAN" (1878-1900) can now be supplied. These sets are very scarce, and early application should be made.

THE CENTRAL LONDON RAILWAY.

H.R.H. the PRINCE OF WALES formally inaugurated the Central London Railway on Wednesday, and, though the line is not yet quite ready for continuous traffic, its opening to the travelling public will not be delayed longer than a few days. An illustrated description of this railway forms the subject of a series of articles now appearing in our columns. We give this week some illustrations of the line and an account of the opening ceremony.

The completion of the Central London Railway marks an event in the history of electric traction unparalleled by any similar event throughout the world. Beyond question this railway stands *facile princeps* among electric railway undertakings. The overhead railways of Chicago, and the lines of the same type now being converted from steam to electric traction in New York, undoubtedly are undertakings each with a greater track mileage than that of the latest of London's underground railways; and some may consider, on this account, that they are correspondingly more important. To the electric railway engineer, however, their significance cannot be regarded as being so great as is that of the important problem just solved by the successful completion of the Central London Railway. The overhead railways of Chicago were merely the adapting of New York steam railway practice to electric traction; there was not, in the same sense that there has been with the Central London Railway, a completely new and unsolved problem to be grappled with and solved. Indeed, it has been rather a whole galaxy of problems—some electrical, some relating to other branches of railway engineering—that the engineers have had to face. To the civil engineers the tunnelling has presented difficulties which were only anticipated in a partial and limited degree by the earlier experiences with the much smaller railway between Stockwell and the City; and the same may be said about the electrical difficulties. If for no other reason, the introduction of high-pressure polyphase generation and transmission cast the Central London Railway problem in a new and hitherto untried mould. Much then depends upon the attainment of the successful issue, of which the royal ceremony on Wednesday was the official and popular expression. Electric railway traction, to an extent which

Digitized by Google

perhaps is little comprehended by the general public, has been awaiting that event. Its occurrence is the signal for marked and widespread extension in the use of electric power for railway traction in this country. An impetus has been imparted which, while directly affecting the multiplication of railways of the same type as the Central London Railway, cannot fail to stimulate indirectly a more rapid development of electric traction of every description.

REVIEWS.

(Copies of any of the undermentioned works can be had from *The Electrician* office post free, on receipt of published price.)

The Management of Dynamos. By G. W. LUMMIS-PATERSON. (London: Crosby Lockwood and Son. 1900).

The extended title of this work describes it as "a handy book of theory and practice." We cannot but regret, after reading the first three or four chapters devoted to the elementary theory of the subject, that the author had not confined himself more exclusively to the practical considerations merely to be expected of a book of this size and nature. At any rate few, if any, of those who would be likely to turn to its pages for enlightenment in the theory of the dynamo would derive much profit therefrom. Without attempting to mention all we take exception to in these first few chapters, we may say we are struck by what is surely an inexcusable contradiction in terms when the writer refers—as he does repeatedly—to the "ends" of a "circuit." Commencing with chapter V., and on to the end of the book, the management of dynamos and motors is really usefully dealt with, and there is a particularly useful little section on the starting of motors and the special devices for this operation. We should have imagined that the management of alternate-current machinery might well have received some notice. For all the attention this type of plant receives it might be practically non-existent. For this reason, and judging from its general tenour, the book would probably be of use only to those in charge of small private plants and isolated installations.

Wireless Telegraphy and Hertzian Waves. By S. R. BOTTONE. (London: Whittaker and Co.). 3s.

Mr. Fahie has recently shown that wireless telegraphy, broadly speaking, has a history going back to 1838. It will soon have a literature. It has passed through the marvellous stage, represented by the newspaper and periodical press, and is now the subject of books. Mr. Bottone's is the latest contribution in this form, but, as the title implies, confines itself to one only of the three orders of wireless telegraphy—the Marconi method.

Chapter I. deals with the elementary facts of electricity shortly and clearly, but this information is not wanted by readers who know anything about the science, and for those who do not it is too scanty to be of any help. Chapter II. is more to the purpose, and deals historically with a few subjects of interest, as the action of charged conductors, lateral discharge, action of discharge on iron filings, electric syntony, and one or two other matters. Chapter III. is excellent so far as it goes. It gives a good *aperçu* of Hertz waves and their application to telegraphy, to firing cannon and mines, and to steering torpedoes; but in a work on telegraphy by Hertz waves one would expect to find this particular application worked out in more detail, giving a view of the whole art and practice, and with some references to the scientific and physical conditions making for and against its use and extension. The fourth and last chapter, occupying 54 out of 113 pages, is devoted to "constructional details," of no use to the general reader, who does not want to make the machinery himself, but to learn something about its working and its possibilities. Twenty-two pages of minute instructions tell us how to make an induction coil, nearly eight pages are given to the making of a Wimshurst machine, and the remainder to the fabrication of transmitters, coherers, relays, bells and tappers, and batteries. Very many of these 54 pages could be better employed in the way we have suggested above.

We have noted a few errors, possibly clerical, in figures and names, and there are, besides, two or three statements of facts to which we must take exception. We do not think that Righi had any share in Branly's discovery, and we are under the impression that Branly himself (not Lodge) observed the property of decoherence in filings and the ways of effecting it, as did Varley and Onesti before Branly (p. 20). The references (pp. 24, 59) to Guarini's "invention called a repeater" and "very delicate and peculiar form of relay" give altogether a false impression. There is nothing peculiar or delicate about it: simply the ordinary relay as used by Marconi actuates (instead of a Morse instrument) another transmitter which sends on fresh strong waves corresponding to the enfeebled ones received (see *The Electrician*, Vol. XLIV., p. 932). Syntony is said to be essential for the detection of electric waves (p. 29 *et seq.*). It is desirable certainly, but not absolutely necessary. The Marconi long-distance apparatus is not syntonised, and if Mr. Bottone can make it so he will have done something for fame.

The "Practical Engineer" Electrical Pocket Book for 1900. (Manchester: Technical Publishing Co., Ltd. 1900). 1s.; in leather, 1s. 6d.

In a technical pocket book one might, from its name, expect to find a collection of tables and memoranda on matters concerning which the owner is likely to require information when away from his office and books of reference, yet it has become the custom that such a book should be a miscellaneous compilation, half text-book, half encyclopædia, embracing for instance subjects as widely apart as dynamo design and statistical data of existing submarine cables; and these so-called pocket books are frequently of such a size and weight as to test to its utmost the capabilities of even a schoolboy's pocket.

The new electrical pocket book brought out by the publishers of the *Practical Engineer*, although excellent value for its price, does not yet, however, fulfil the ideal of what a book of this class should be. Its convenient size and shape ($5\frac{3}{4}$in. × $3\frac{1}{2}$in. × $\frac{1}{2}$in.) certainly affords no ground for complaint, but considering the wideness of the subject and the impossibility of dealing with it educationally, practically and in detail in 250 small pages, it is to be regretted that the editor has not omitted those parts which are purely of the text-book order, and replaced them by useful tables of which there are already some—but, alas, too few—excellent examples in it. For instance, the chapter on magnetism occupies more space than that on electric traction, and the only tables in the latter section are some giving the relative costs of working, &c., on horse, cable, steam and electric lines. In another part of the book, reference is made to Matthiessen's standard, but no value of it is given, and a table of "feet per ohm" for solid wire and stranded cable is calculated to four and five figures, but it is not stated to what standard they are calculated. The areas and circumferences of circles are given for diameters, advancing by eighths of an inch, it being forgotten apparently that wire is gauged in decimals of an inch. In the section on polyphase systems, no formulæ are given for the currents carried by the several wires for transmitting a given power at a given pressure. The "earth-lamps" method is cited for indicating leakage on mains, but it should have been added that it is useless in the majority of existing three-wire networks in this country so long as the permanent Board of Trade earth connection is left on the middle wire. The table of the "most valuable types of primary cells in common use" should include the Fuller double-cell bichromate battery.

We hope to see a second, and indeed a third and fourth edition of this pocket book in which the above-mentioned defects are rectified.

The Slide Valve Simply Explained. By WILLIAM J. TENNANT. (London: Dawburn & Ward, Ltd.)

This little pamphlet—one of the "Model Engineer" series—should prove of great help to those many budding engineers who find the intelligent following of the movements of the slide valve an intellectual poser. The illustrations, being clear, generally well fulfil their function, and the author is to be commended for recognising the importance of showing what is the full effect of altering any particular quantity in the valve dimensions or movements.

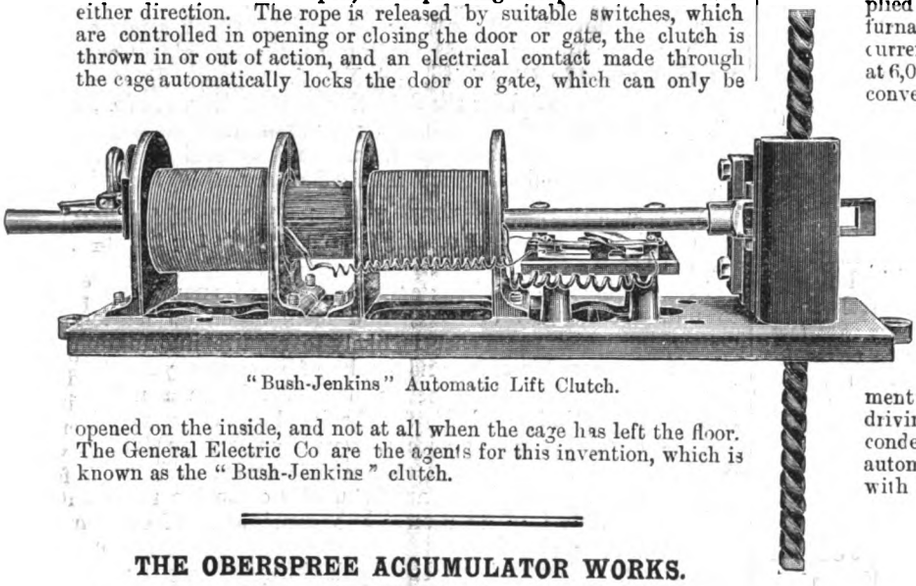
AN AUTOMATIC SAFETY LIFT CLUTCH.

There has recently been patented and placed on the market a new safety lift clutch, which is automatic in action, and is claimed to be the simplest and most effective safety clutch in use. It is further claimed that with it the possibility of lift accidents due to the cage being moved away from the floor while the door is still open, or insecurely fastened is prevented. The lift cannot be started when the door is open, nor can any lift-door be opened excepting the one at which the lift is stationary. In the illustration the clutch is shown with the starting rope seized. This condition is maintained all the time the door is open, the rope being incapable of motion in either direction. The rope is released by suitable switches, which are controlled in opening or closing the door or gate, the clutch is thrown in or out of action, and an electrical contact made through the cage automatically locks the door or gate, which can only be opened on the inside, and not at all when the cage has left the floor. The General Electric Co are the agents for this invention, which is known as the "Bush-Jenkins" clutch.



"Bush-Jenkins" Automatic Lift Clutch.

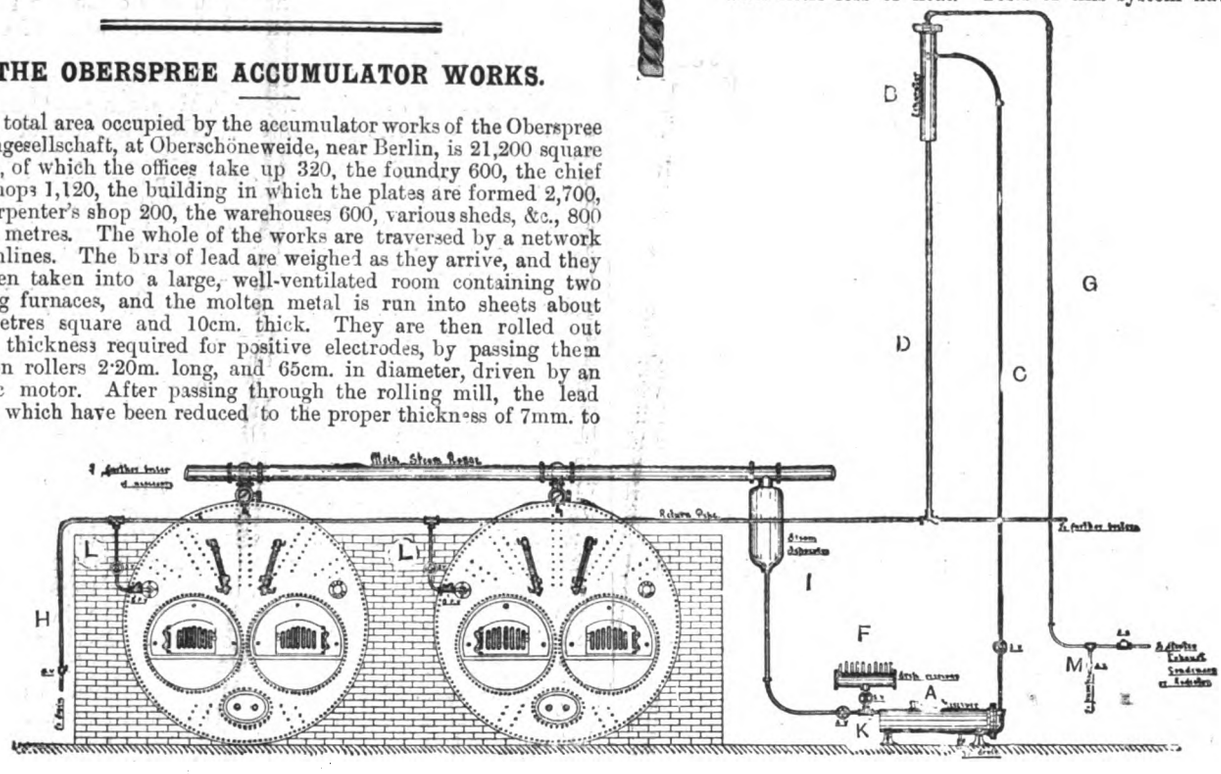
THE OBERSPREE ACCUMULATOR WORKS.

The total area occupied by the accumulator works of the Oberspree Aktiengesellschaft, at Oberschöneweide, near Berlin, is 21,200 square metres, of which the offices take up 320, the foundry 600, the chief workshops 1,120, the building in which the plates are formed 2,700, the carpenter's shop 200, the warehouses 600, various sheds, &c., 800 square metres. The whole of the works are traversed by a network of tramlines. The bars of lead are weighed as they arrive, and they are then taken into a large, well-ventilated room containing two melting furnaces, and the molten metal is run into sheets about two metres square and 10cm. thick. They are then rolled out to the thickness required for positive electrodes, by passing them between rollers 2·20m. long, and 65cm. in diameter, driven by an electric motor. After passing through the rolling mill, the lead sheets, which have been reduced to the proper thickness of 7mm. to 8mm., are cut up into plates of the required size by an electrically-driven circular saw. The plates are next taken to the principal workshop, which contains 18 Majert-Berg planing machines (see *The Electrician*, Vol. XLIV., p. 218), which turn up a series of thin shavings on the rough lead plate. The Majert positive plate in its most recent form is stamped out with a stiffening rim. instead of having the latter burned on to it as formerly. The grids for the negative plates are cast in another room, in moulds of the well-known pattern, and about 6,000 can be turned out daily. These castings are trimmed by a circular saw, and then taken to a room where they are cleaned by means of a sand blast, and are well brushed, after which they are taken to the pasting room. Here the active material, which has been prepared in an adjoining room, is applied to them by hand. From the pasting room the plates are taken to the forming room, which contains about 1,000 vats, capable of holding 20,000 plates. At about the level of the height of the vats there are exhaustors, opening into underground channels, to carry off the air laden with sulphuric acid spray and the gases given off in formation. After the plates have been discharged and washed, they are dried on frames in a current of air, and prepared for sending off. In this part are also stored the glass and other containing cells.

On the first floor of the building in which the plates are formed is the testing room of the electrical laboratory, and in the passage near it is the main switchboard, and a large window which enables the whole of the forming tanks to be kept under observation. The chemical laboratory is on the next floor, and amongst other features worthy of notice is the plant for producing water-gas, which is capable of yielding 20 cubic metres of gas per hour for use in the laboratories, and for soldering, &c. The steam required for heating the factory is supplied from two boilers, and the administrative block is separately heated. Washing and bathroom accommodation is supplied for the employés, as well as dining rooms. Next to the furnace room is the chamber in which the pressure of the current supplied by the Allgemeine Elektricitätsgesellschaft at 6,000 volts is transformed down to 70 volts or 80 volts, and converted into continuous current for use in the tanks and for lighting purposes. In the factory, which is thoroughly equipped in every respect, about 250 hands are employed, while 150 are engaged in installation work. The description of works given in No. 8 of the *Centralblatt für Accumulatoren und Elementenkunde*, from which the above is taken, contains six large illustrations of the various rooms in the factory.

THE HOLLY GRAVITY RETURN SYSTEM FOR STEAM PIPES.

The accompanying illustration shows the arrangement of steam pipes for the "Holly" system of steam driving. This apparatus is arranged so as to draw away the condensed water from steam pipes and return the same automatically and continuously to the boilers, consequently with little loss of heat. Tests of this system have been recently carried out at the Huddersfield electricity supply works where the apparatus is erected. The Huddersfield apparatus is capable of returning 3,000lb. of condensed water per hour to the boilers, an amount of liquefaction and priming which no central station engineer would wish his steam plant to exceed or even attain to. The apparatus is attached in 16 positions to the main steam pipe draining the condensed water from this into a drip receiver. From the drip receiver it passes to a main receiver, and thence, partly by steam pressure and partly by suction, to the separator which is fixed about 25ft. above the boiler water level. Thence it returns by gravity to the boilers. Tests carried out show that the average amount of water returned per hour was 384lb., the temperature of the condensed water thus returned being 363deg. The heat saved per hour was 273 heat units, representing, with coal at 12s. per ton, a saving of £35. 18s. 9d. per annum. As the cost of the arrangement is only about £100, it will be realised what a great profit-making apparatus it actually is. We have taken the details relative to these tests from a report drawn up last August by Mr. A. B. Mountain, the borough electrical engineer at Huddersfield.



The Holly Gravity Return System for Steam Pipes.

ELECTRICITY SUPPLY FOR SMALL TOWNS. *

BY C. S. VESEY BROWN.
(City Electrical Engineer, Lincoln.)

The subject of the Paper, as suggested by the Council of this Association, was "The Best System of Supplying Small Towns," but the above title was substituted, the object aimed at being to elicit, by discussion, the experiences and ideas of those members of the Association who have given the matter their attention. There is no doubt that the rapid advances which have been made in electricity supply in the larger towns of Great Britain, coupled with the facilities which modern legislation has provided for the purpose of municipal ownership of such undertakings as gas, water, electricity and tramways, has prompted the smaller and possibly less densely populated and prosperous districts to apply for statutory powers under the Electric Lighting Acts.

For the purposes of this Paper, the author has chosen those towns and districts with a population not exceeding 40,000. At the end of 1899 there were in operation six towns under this size: 56 works (28 owned by local authorities and 28 by limited companies); there were also 161 local authorities and 23 limited companies who had acquired statutory powers, of which number 50 local authorities and 16 companies were reported to have completed arrangements for equipping works, thus leaving 111 local authorities and seven companies who had not made up their minds what to do. Of these 111 local authorities, the following obtained their provisional orders on the dates given—viz., one in 1890, two in 1891, four in 1892, two in 1893, and two in 1894, and of the remainder the larger proportion were granted in 1897, 1898 and 1899. There are also a large number of applications during the present session, of which it is difficult to give an exact account until the orders are granted.

The analysis of the works in operation, as regards system of distribution, is as follows:—

Local Authorities.		Limited Companies.	
High Tension Alternating.	Low Tension Continuous Current.	High Tension Alternating.	Low Tension Continuous Current.
11	17	12	16

and the capital expenditure and results from those in operation for more than one year is as follows:—

	Local Authorities. 14 Towns.		Limited Companies. 9 Towns.
Capital Invested	£406,175	...	£332,490
Average profit after payment of working expenses	4½ %	...	4½% (average dividend)
Kilowatts installed	5,240	...	3,065
Average price per B.T.U. obtained	5·1d.	...	6·4d.

It will be seen that to a certain extent the local authorities have been oblige to subsidise their works with contributions by the general body of ratepayers, for in order to pay interest and sinking fund on the capital invested at 3 per cent. and repayable in 25 years, a return of at least 5¾ per cent. is needed. The author tried to investigate the corresponding gas returns for these towns, but owing to the involved accounts of new and old capital, different rates of interest, and also the fact that, as a rule, the gas companies supply outside the local authorities' area, the figures would not have been of any real value as a comparison.

Having obtained the necessary powers, the local authority's attention is at once directed to a number of questions, of which the following are the more important:—

A choice of system.

A selection of a site.

The question of an expert to advise on what is to be done and how to do it.

The capacity of the generating plant.

The extent of the area of supply to start with.

Whether or not street lighting should be undertaken.

The price of supply, and on what terms there should be a rebate, according to the consumption of electricity.

Are "free wiring" contracts to be entered into, &c, &c.

It is one of the good fortunes of this country that the municipal government, as a rule, is carried on with the firm desire to do what is best for the "citizens," and the author makes no exception to this rule in the case of electricity supply, and begs respectfully to point out to the local authorities in question the advantages of sinking all differences of opinion in politics, &c., when dealing as trustees to a commercial undertaking for the benefit of the general public. If the expert's advice can be depended upon the local authority can leave all technical details alone, and exercise in a greater degree those commercial and managerial qualifications which it is presumed have placed them where they are.

The choice of an engineer to advise and superintend the scheme is a knotty point to solve in some places. At times the surveyor is asked to carry out the works. Other places depend on a scheme propounded by manufacturers; and, again, some authorities appoint an engineer, after considerable expense in advertising, at the wage of a first-class foreman, who is supposed to be competent to advise on all the intricate questions in the maintenance and construction of the undertaking, which though small in size and area, yet has principles involved which require the same consideration as if the undertaking was to supply a greater district; and not only is he called upon to carry out this undertaking, but to draw plans and specifications, and in contracts provide himself as sole arbiter in cases of dispute with manufacturers, who may have in their employ engineers and experts of world-wide fame. The author's suggestion to small local authorities is that they should employ a competent expert to advise and initiate a policy and system, and for the first stage of the undertaking pay him the usual fees; that then they should engage a resident manager, whose duties would be to manage both commercially and technically the whole undertaking, and that as extensions are required, the consulting expert should be called in to advise, he being paid an annual retainer to cover the advice given. In this manner the local authority would obtain the maximum of expert advice with the minimum of expense, and in connection with this suggestion the author would point to the very magnificent results which have been obtained by gas, water, and railway undertakings where somewhat similar arrangements have been made.

The site for an electricity works should be, if possible, near to a stream of water and adjacent to a coal depôt. If preference is to be given to either situation, that where easy arrangements can be made for condensing the exhaust steam is preferable. In the author's opinion it would be a difficult matter to find a better system than the three-wire continuous current, supplying consumers at a pressure of 200 volts to 250 volts, the choice of pressure being determined by the probable extension of the feeder cables. The generating plant should be of a simple and yet efficient character; nothing should be installed which has not stood the test of time and experience. Lancashire boilers, or where it is possible that foggy weather may be experienced, water-tube boilers are equally suitable; 125lb. to 130lb. steam pressure seems to be the most suitable standard to adopt. The addition of an economiser or feed-water heater is distinctly an advantage, and should not be omitted, especially where the character of the feed-water necessitates some depositing apparatus to soften it. The steam and feed pipe arrangements should be of the best character. There should be no possibility of joints failing or valves leaking, and in the whole of the system of electricity supply there is no policy more penny-wise or pound-foolish than that of the substitution of inferior material or curtailment of expense in this part of the generating plant. The engines and dynamos should be direct coupled to each other, and as far as possible should be arranged in standard sizes. By "standard" sizes is meant the standard size of any manufacturer as near to the expert's "standard" as possible; if the expert's "standard" is insisted on, additional expense is incurred, which in the author's opinion is not warranted.

At the first stage of the undertaking, it is probable that two or three sets of from 50 kw. to 100 kw. each would be installed, and that as extensions are required 150 kw. to 250 kw. machines would be added, the sizes depending on the probable demand to be made for power and traction, as well as for lighting. Compound two or three crank engines appear to be the most useful type. The dynamos, for the first stage, should be so arranged that they will balance the three-wire system, if necessary, without the assistance of a storage battery. A storage battery should be provided of sufficient capacity to take all the lighting that may be required between midnight and some time in the afternoon of the next day, for, say, two years, after which time it acts only as a "safety valve" to the supply pressure. The switchboard should be so arranged as to be easily extended, and at the same time confined to as small a limit as is consistent with safety and ease of controlling the supply. Recording instruments for various purposes should be used. There is nothing more annoying than to be assailed occasionally with the statement that the supply is or was unsteady at some specified time, and there should be recording voltmeters to refute or confirm such statements. Each dynamo should be provided with a recording instrument to enable its output to be calculated.

Sufficient attention is not paid to the necessity for keeping accurate records of everything in an electricity works. The author has had occasion lately to examine the accounts and records of most of the undertakings at work in the country, and is surprised to find that, for example, records as to the number of units generated, or the amount of cable laid, and other details essential to the good order of such an establishment are not kept. In the minor details of the works, the author is inclined to use motors for driving the various pumps, economiser scrapers and cranes that may be required, but would make an exception in the case of providing a reserve steam-feed pump. With regard to the distributing system, concentric and triple concentric cables are most suitable. These should be laid on what is known as the "solid" system, which serves the double advantage of forming a mechanical protection against picks and water, and also against electrolytic effects, which may be

* Paper read before the Municipal Electrical Association, at Huddersfield, June 20th.

Digitized by Google

deleterious to armoured cables buried direct in the ground, where tramways are in operation. The author prefers to adopt one standard size of cable (say, 0·075 sq. in. to 0·125 sq. in. sectional area) throughout the distributing net-work, and to throw out feeders of different sectional areas to different parts of the net-work as the demand increases, and by a judicious selection of the size of feeders, it should be possible at some future date, if the district which is being supplied increases in value or importance, to use the feeder cables already laid as distributors, and re-lay larger feeder cables, for just as the gas and water companies commenced operations with small pipes, &c., so does the electricity undertaking commence operations with small plant and cables. The meters used in consumers' premises should be well tested before being put on the circuit.

With regard to the price of supply, the author is inclined to the adoption of a price which will require little variation in the future. If a high price is fixed to start with, it is certain to have the effect of restricting the output, even though a profit may be made, and the intention of the legislature in granting the local authority powers (which amount to an absolute monopoly) is undoubtedly not that electricity should be for the rich, but for those who desire to avail themselves of it; and in connection with these remarks the author would add that a broad policy of extending the network cables over a considerable area of the district each successive year will have the effect in the long run of establishing a good connection amongst all classes of inhabitants.

In concluding this Paper, the author would refer to the supply of electricity in those towns where the gas undertaking is carried on by the local authority, and would suggest the following possible solutions of the difficulty which may occur in these cases:—

(1) If the town is within the area of supply of one of the large power distributing companies who are or will shortly be operating, then a cheap and efficient way would be to lay down a net-work of distributing mains, and allow the company to supply "in bulk" what electricity is required, the local authority retaining the distribution of the energy and the collection of the accounts in their own hands.

(2) To lay down a net-work of distributing mains, and instal a gas engine plant to the extent of probably 15 kw., as a pioneer undertaking, and if the demand requires, then to put up a steam generating plant.

The author has felt some diffidence in going beyond the bare outline of the suggested arrangement for dealing with this problem of supplying these small towns,* and hopes that the discussion will elicit information which will be useful to guide the powers that be into the right groove towards the establishment of efficient and successful electricity works all over the United Kingdom.

*On account of the many varied conditions which obtain, say for example, in towns in Devonshire, Staffordshire, Durham County, or in the North of Scotland.

CORRESPONDENCE.

ELECTRIC TRACTION CURRENTS AND SUBMARINE CABLE WORKING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In connection with Prof. Jamieson's ingenious theory as to the manner in which the stray sheathing currents have affected the cable at Cape Town, it seems to me that his conclusion as to the nature of the disturbances being electromagnetic is an extremely doubtful one. In a comparatively well conducting homogeneous electrolyte like sea water, it

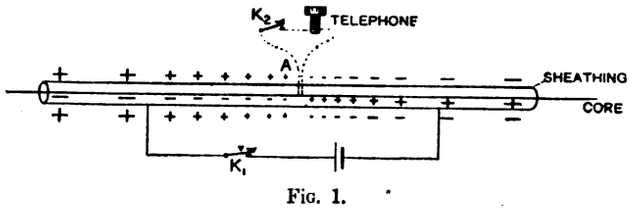

FIG. 1.

seems difficult to imagine a slope of potential of any appreciable magnitude at a distance apart expressed in terms of a single diameter of the cable. During June last year I personally observed a maximum difference of potentials between Robben Island and Cape Town, due to tramway disturbances, which only slightly exceeded one volt.

There are two main disturbing effects, both electrostatic in character, which I think sufficiently account for the phenomena observed, and which I have only just had an opportunity of verifying experimentally. First, consider the case of an ordinary armoured or lead-sheathed cable having the conductor of its core completely insulated (Fig. 1). The difference of potential due to the stray external current has the effect of simultaneously disturbing the normal electrostatic charges on the copper conductor within the dielectric. This results in a redistribution of charges with every variation of the external potentials, and consequently is responsible for internal surgings of charge which sympathetically affect the receiving condensers. By placing a sufficiently sensitive detector in the conductor circuit near the neutral zone at (A), the effect of these surgings becomes apparent. In further proof of the electrostatic character of these undulations, by joining up a

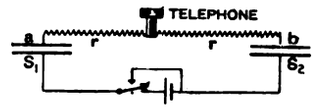

FIG. 2.

key and telephone or other detector, as shown by the dotted lines, and releasing k_2 before k_1, and then again depressing k_2, the click due to the re-arrangement of charges becomes audible.

The case is indeed analogous to that shown in Fig. 2, where S_1 and S_2 are elements of the sheathing at different potentials; (*a*) and (*b*) the elemental portions of the conductor which become charged inductively, whilst *rr* is the resistance of the conductor separating (*a*) and (*b*).

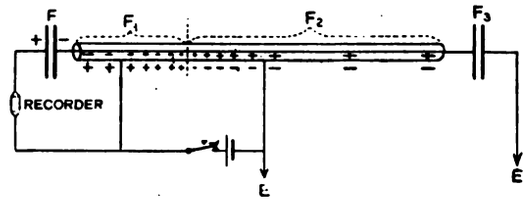

FIG. 3.

Fig. 3 represents the state of affairs in the general case where condensers are used at both ends of the cable. (Compare with Fig. 3A). The condenser F_3 at the distant end may be considered an extension of F_2; or, if instead of it we insert a resistance of 10,000 ohms or more, it acts simply as a leak across F_2. Quite apart from these surgings between F_1 and F_2, the potential due to the stray current operates in charging the signalling condenser F, and the main portion of the cable F_2 in cascade, as pointed out by Mr. Alfred Hay; and the recorder being in that circuit, it is the combination of these effects which disturb the receiving instrument.

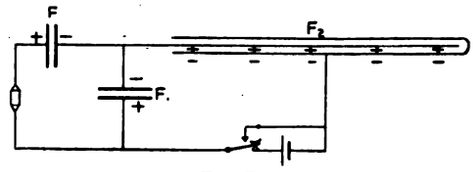

FIG. 3A.

With these explanations of the phenomena it is evident that perfect compensation can alone be secured by means of a twin core cable, which should be laid out well beyond the limits of the affected district.—Yours, &c., C. W. SCHAEFER.

Gibraltar, June 12.

ADJUSTABLE HIGH RESISTANCES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: It may interest some of your readers to know that an excellent and easily adjustable high resistance for use in the "Modified Thomson Capacity Test," recently described by Mr. Elton Young, can be obtained by using ordinary glass siphon tubes filled with water. Their value can, of course, be adjusted by putting a sufficient number of tubes in parallel or series or by altering the conductivity of the water. I find that a tube 8in. long, filled with ordinary drinking water, has a resistance of 25 megohms.—Yours, &c.

Lima, Peru, June 12. A. DAVIDSON.

THE B.E.T. SUPERANNUATION FUND ASSOCIATION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: With reference to the remarks which you were good enough to make on p. 311 of your issue of June 22nd on the subject of the B.E.T. superannuation scheme, it may be of interest to state that the rules relating to the adhesion of our own associated undertakings to the scheme are equally applicable to other electrical companies wishing to make pension arrangements for their staffs, and the directors of the B.E.T. Company are favourably disposed to extend the scheme to such other companies as may desire to join.

There must be many electrical concerns desirous of making proper provision for the old age of their salaried officers and clerks, but unable, owing to smallness of numbers, to start a superannuation fund of their own. The Railway Clearing House superannuation fund was devised to provide for similar circumstances, and the B.E.T. scheme is based on the model of the Railway Clearing House scheme.

The affairs of the Association will be managed on independent lines by a representative committee, and ample protection will be afforded both to the fund and to the officer in the event of his associated company withdrawing from the fund.

Mr. W. G. Bond is acting as secretary to the committee having charge of the matter, and he will be prepared to give further information upon application to him at this address.—Yours, &c., E. GARCKE.

Donington House, June 27.

PARLIAMENTARY INTELLIGENCE.

MUNICIPAL TRADING.

The Joint Committee on Municipal Trading resumed its sittings on Friday last, the Earl of Crewe presiding.

Mr. EMILE GARCKE said that during the last 18 years he had been concerned in the promotion of electrical companies. He formed and was managing director of the British Electric Traction Co., which had a capital of over £1,C00,000, and was interested in nearly 60 tramways and light railways in various parts of England. The concessions which the company held brought it into relation with something like 200 local authorities, and he had consequently had opportunities of looking at the question of municipal trading from all sides. He was very largely in sympathy with the evident desire of many local authorities to extend the sphere of their operations and to undertake industrial enterprises. He was in favour of the municipalisation of industrial undertakings which had for their object the rendering of public services, and which could be better carried out by elected bodies than by public companies or private capitalists, but he was strongly opposed to what was called municipal trading. Any undertakings carried on by local authorities should be so carried on with a view of rendering a service better, more efficiently, and more cheaply than could be done by private enterprise, and not with the view of making profits. Any surplus should be applied in reduction of the price or in reduction of the capital account created for the purpose of the undertaking and not in reduction of rates or in providing for some other enterprise.

The CHAIRMAN: What is your objection to applying a surplus to some other object of equally general use?—I think it would be bad finance to do so. The Nottingham Corporation the other day boasted that they were able to pay for their technical institution out of the profit they made on their gas undertaking. I think that is a wrong view to take. The technical institution, if it is a desirable institution, should be initiated and carried on independently of whether they make a profit on the gas undertaking or any other undertaking. I think it would lessen financial control if the surplus on one undertaking were devoted to making good a deficit on another.

Sir W. FORTEE: You are aware that the Post Office makes a large profit. Do you think that bad finance?—No, but I should think it bad finance if the profits were applied to some other undertaking without separate accounts. Many local authorities were working their undertakings with a view to profit. On the average corporations supply the electric light at rather less per unit than the companies, but they were in a somewhat better position for producing electricity economically, inasmuch as 60 corporations supplied electricity for public lighting, whereas companies had very great difficulty in persuading local authorities to go in for public electric lighting.

The CHAIRMAN: What is your objection to municipalities working at profit?—I think the foremost is the danger of municipalities over-trading they are allowed to extend their enterprises with a view to a profit without a limit or restriction. A corporation having an electric lighting order was most anxious to take up electric tramways for one of two reasons—either because they had made a profit on their electric lighting or because they wanted to largely increase the demand for electricity and thus render remunerative an electric lighting undertaking which would not be remunerative as a lighting undertaking alone. There were several instances in which local authorities who had obtained provisional orders had not taken up electric lighting because they were doubtful whether there would be a sufficient demand for such lighting. When, however, he went forward and asked for a concession for electric tramways, the first question they asked was whether he would buy his electricity from them if they put up a station. There were several cases in which he had made such an arrangement, and had had to wait for the electricity for his tramways until the local authorities were able to establish an electric lighting undertaking, which they probably would not have established but for the possibility of obtaining a large customer for the tramway. He would give the Committee one instance of what he regarded as bad treatment on the part of a local authority. He was interested in the development of a very large electric traction scheme in South Staffordshire, and their railroad company undertaking to supply electrical power over nearly the same area. Some of his representatives went to one of the local authorities in the district, and asked for their consent to the substitution of electric for steam traction on the tramways. The local authority suggested that he should purchase the electric current from them for the purpose of the tramway. His representative replied: "You had not got a power station, and are not likely to have one, for you are in treaty with the other company to take current in bulk." The answer was: "Oh, but we can buy our electricity from the other company and sell it to you at a profit." He thought that municipal trading could hardly be carried farther than that. He considered that it was contrary to the public interest that such things should be done, because it prevented a company giving the lowest fares or working their lines in the most efficient manner. In the case of the electrical industry, he thought that considerable harm had been done to the country generally by the attitude taken up by local authorities. After the passing of the Act of 1888 many local authorities refused to grant concessions to electric lighting companies, and applied for provisional orders themselves. For many years, however, nothing was done to carry out those provisional orders. About one-third of the orders granted to local authorities had not been proceeded with. English electrical manufacturers had been hungering for orders for electrical machinery, but they had been unable to establish large factories. Meanwhile electrical manufacturers on the Continent and in America had had the benefit of supplying the electric light for many years past and had been able to establish large factories, to take up all kinds of experimental work and to develop the industry in every way. The result was that the English manufacturing companies were not in as good a position to deal with the demand that had now sprung up as were foreign manufacturers. Consequently a very large proportion of the electrical apparatus needed was being imported from America and elsewhere. In 1899 the exports of telegraphic apparatus from this country amounted to £1,000,000, while those of miscellaneous electrical apparatus amounted to only about £400,000. It was clear that the telegraph industry, which was not hampered in this country, was in a far better position than any other department of electrical industry. The imports of electrical apparatus for the first two months of this year amounted to as much as £125,000, and this figure did not include the rails and cars, a large proportion of which came from America. He was promoting a system of electric tramways in the district between Leeds, Bradford, and Halifax, and the question had arisen as to the gauge that should be adopted, inasmuch as each of the three towns mentioned had a different gauge. If the tramways in those towns had been in the hands of companies when mechanical traction was adopted he believed that they would have had sufficient insight to have seen that it was necessary to have the same gauge in each of the three towns. He thought it highly desirable that the veto of the local authorities on the operations of companies should be modified.

Mr. A. A. CAMPBELL SWINTON expressed a strong opinion that the great backwardness of this country in electrical matters was almost entirely due to the opposition encountered by companies from municipalities. He agreed with Mr. Garcke and witnesses that municipalities should not be allowed to make profits.

On Tuesday, Sir BENJAMIN BROWN (Messrs. R. W. Hawthorn, Leslie & Co., shipbuilders, Newcastle) said he had experience as a member of local authorities and had also been a director of two electric lighting companies He did not consider that local bodies were suitable authorities for carrying on trading enterprises, particularly as regarded electric tramways. At the same time he thought the power of doing street work themselves ought to be given to the local authorities. He did not think there was much objection to a local authority purchasing electricity in bulk and distributing it to consumers. The development of electric lighting had, in his opinion, been largely interfered with by the policy adopted by local authorities in opposing the formation of companies for supplying electric current. The backwardness of this country in regard to electrical enterprise was largely attributable to the way in which private enterprise had been discouraged.

Mr. W. M. MURPHY, chairman of the Dublin United Tramways Co. and of the London Southern Tramways Co., said that for many years he had been largely interested in the promotion, financing and construction of tramways throughout the United Kingdom, and was now engaged in constructing electric tramways to connect Ramsgate, Margate and Westgate. Electric lighting in Dublin was in the hands of the Corporation and had not been successfully worked. He ascribed the failure to mismanagement and want of enterprise. Last year Dublin charged consumers 6·1d. per unit, and lost money by it. The Cork Tramways Co., on the other hand, which had an electric lighting order, charged only 2·98d. The advance which had been made in the United States in regard to electricity was, in his opinion, due almost entirely to the freedom which the American companies had had. When horse tramways were first introduced into Europe from America they spread from England to the Continent, and several of the Continental lines were built by English enterprise and capital. Now a condition of things which was exactly the reverse of this was observable. In the case of the Cork tramways he got an offer

Digitized by Google

of capital from France, and, in fact, it was French capital which built the line. There had, of course, been cases in which municipalities had been successful in working tramways, but where a local authority became possessed of a tramway undertaking that had been worked for 21 years, and took over the whole of the staff, it could not very well fail to succeed. The legislation which gave local authorities the right to purchase tramway undertakings after a certain period was a great discouragement to capitalists, who would otherwise invest money in tramway schemes. Parliament had set its face against the exaction of wayleaves by local authorities from tramway companies, but they were still paid under private agreements between the parties. The local authorities, of course, had a right to withhold their consent to a scheme unless their conditions were complied with, but in some cases they tried to exact conditions of too onerous a character with the result that schemes were abandoned. He himself had had to abandon tramway schemes from this cause more than once, one of those so abandoned relating to a proposed line at Dumbarton.

Lord AVEBURY (Sir John Lubbock), president of the Associated Chambers of Commerce and of the English Bankers' Association, said he believed the majority of the mercantile community viewed the spread of municipal trading with apprehension, and most of the Chambers of Commerce were opposed to it. The municipal debt had shown in late years an alarming tendency to increase. Hitherto investors had considered that in taking up municipal loans they were making an investment which had no appreciable risk, but if a municipality was to engage in trading operations there must be an increase of risk. The more money a municipality had to borrow the greater amount of interest it would have to pay, though, of course, if a local authority had a very well paying undertaking in its hands that would tend to improve its credit. He was of opinion that the action taken by local authorities under the Electric Lighting Acts had had the effect of checking the development of the electric light and other electrical enterprise in this country. Bills to enable companies to supply electric power to manufacturers had been opposed by municipalities, to some extent successfully, though he thought it clear that if power was to be distributed in the cheapest possible manner it must be from some considerable centre. He also thought it clear that no single municipality was likely to be able to supply electric power as cheaply as a company. One effect of trading would be to involve local authorities in labour questions, and he thought it undesirable that the members of a Corporation should have to settle the wages of their own constituents.

The Committee adjourned till to-day (Friday).

LONDON COUNTY TRAMWAYS.

On Friday the Committee of the House of Commons, presided over by Mr. W. H. Holland, resumed discussion on this bill (No. 1).

Mr. ALFRED BAKER, tramways manager to the London County Council, speaking as to the results of the working of the Council's tramways on the south side of the Thames, said the gross receipts for 1899 were £467,000, and the working expenses £377,964, leaving a balance of £89,036. Interest on capital came to £45,000, which made the net surplus £44,000. He anticipated an improvement of these figures from the conversion of the tramways to electric traction. Experience of electric traction in other places showed that by its adoption receipts increased and expenses diminished. The published accounts of the Glasgow Corporation showed that, for the year to May 31, 1899, the receipts from horse traction were 11·51d. per mile run, and expenses were 8·51d., leaving a margin of 3d. per mile. During the same period the Glasgow electrical tramways receipts reached 13·89d. per mile, and the expenses only 6·38d., leaving a profit of 7½d. per mile, a difference in favour of electric haulage of 2·38d. on receipts and of 2·13d. on working expenses. The receipts per mile on the London County Council's system in South London were at present only 10·64d., the fares being very low, and the expenses were 8·52d., leaving a profit of 2·12d. per mile run. If electric traction were substituted he estimated the receipts would rise to at least 1s. per mile. That was an estimate 2d. below the receipts in Glasgow from electric traction, whereas the Council's receipts from horse traction were only 1d. less than in the case of Glasgow. The Council's expenses should not exceed the horse traction expenses, 6·38d., which would leave a balance of 5½d. against 2·12d. with horse-power. Last year the tramway miles run over the 8 miles of lines proposed to be electrically equipped in South London were 1,917,160, so that the difference on that mileage would amount to £27,000 increased profits. The alteration of the system of haulage over these 8 miles would release 900 horses, which would greatly conduce to an improvement in the sanitary condition of the streets. There would also be an economy of space, as the electric car would carry 70 passengers, against the 46 of the horse car, and would occupy 5ft. less of road space. The electric car would be over all 31ft., whereas the measurement of the horse car and pair of horses was 36ft.

The case for the promoters being closed, the evidence of a large number of local witnesses was heard against the tramway extensions proposed.

Mr. FRANK DODD, for the St. Saviour's District Board of Works, asked the Committee to insert a clause that the County Council should be liable for any damage done by leakage of electricity to the property of anyone along the tramway routes. He said that, while he accepted the assurance of Prof. Kennedy that no leakage would take place under the systems to be adopted, yet electricity might escape by accident or otherwise, and it was reasonable to ask that nothing under the Act should exonerate the Council from liability.

Mr. VESEY KNOX, for the Wandsworth District Board of Works asked the Committee to strike out the provision from the bill before the Committee providing for the electrical equipment of the Westminster and Tooting tramways. As a similar power was included in bill (No. 2) and the Wandsworth Board asked for power of veto with reference to the surface-contact system, the board considered they ought not to be called upon to oppose the same proposal in two bills.

Mr. POPE, Q.C., for the promoters, said that whatever provisions had been or might be inserted in bill (No. 2) in favour of the local authorities should also be placed in the present bill.

Mr. H. J. MARKHAM, surveyor to the parishes of Streatham and Tooting, said two systems of traction were put forward by the Council—the surface-contact and the conduit systems. There was no objection to the conduit system, but the surface-contact system was an experimental one. It might be dangerous to the traffic and would certainly be inconvenient where a gradient occurred. There was an incline of 1 in 22 on the proposed route, and if a series of plates were placed in the road 18in. in length there would be danger to horse traffic. The Wandsworth Board therefore desired to retain a veto in regard to the surface-contact system, or any other system that had not been properly tried.

Mr. H. EDWARDS, surveyor to the Lambeth Vestry, said he considered the surface-contact system would not be suitable. He agreed that the knobs or studs projecting up in the roads would be very dangerous, especially to cyclists. The centre of the plates would be formed of metal and the remainder of another material, probably unequal in its wear.

On Tuesday, after hearing the addresses of counsel, the Committee decided that the preamble of the bill had been proved, inclusive of all the new tramways proposed. The application of Wandsworth and Lambeth in respect to placing the mains from the generating station to the tramways under the Electric Lighting instead of the Tramways Acts was refused. With respect to injury from nuisance, the Committee considered it was quite right for the Council to be liable for any injury caused by their own negligence, but not for injury arising otherwise. With reference to omnibuses, the Committee considered that it was inevitable in the march of improvement that omnibuses should be supplanted in some streets to meet the needs of a growing population.

The clauses were adjusted, and the bill was ordered to be reported.

WELLINGBOROUGH AND DISTRICT TRAMROADS BILL.

This bill came before a Select Committee of the House of Lords, presided over by Lord Fermanagh, on Tuesday.

Mr. BALFOUR BROWNE, Q.C., said the bill was promoted by the British Electric Traction Co. for the purpose of constructing tramroads in the county of Northampton. It was proposed to make a line beginning at Wellingborough, which had a population of 20,000, whence (from the centre of population) it passed to the goods yard of Wellingborough station on the London & North-Western Railway Co., so as to carry passengers the considerable and inconvenient distance between the two places, and thus feed the railway company. From this place the line would run to Irchester, where it would enter the station yard of the Midland Company, and so lead to an exchange of traffic to the mutual advantage of both. Thence the line would pass to Rushton on to Higham Ferrers, going north again to Higham Ferrers station on the London & North-Western Railway, and so on to Raunds. To complete the circle it was proposed to pass through Irthlingborough and Finedon, returning to Wellingborough station on the Midland. The whole district, with a population of from 60,000 to 70,000, and all the local authorities supported the proposal, and not only offered no objection, but were anxious to have the tramways. The only petitioners were the London and North-Western Railway, who objected to a level crossing proposed by the bill. That company, although they crossed 22 public roads on the level between Northampton and Peterborough, objected to the tramway crossing their line at one place. The objection was utterly unreasonable, because the road belonged to the public, and there was no danger. In Hull, where they had electric tramways, there was not a single electric line which did not cross the lines of the North-Eastern Railway Co. on the level; and the traffic in a town like Hull was infinitely greater than on a country road between Wellingborough and Irchester. The Committee of the House of Commons which considered the bill passed the preamble, but hoped the promoters would be able to come to some understanding with the railway company with a view to constructing a bridge, to which both parties should contribute. Negotiations had followed, but the railway company stated that they could not approach the promoters with any offer of constructing a bridge in lieu of a level crossing, and so no progress had been made.

Mr. C. WOOLESTEN, member of the Northampton County Council said it was of importance that when goods were placed on a tramcar to be transferred to a railway that the car should enter the goods yard of the railway so that the exchange of traffic could take place without cartage. As to the objection of the London & North Western Company to the tram crossing their line near Wellingborough station on the level, it was on a main road, and the proposal had received the approval of the County Council, who were the road authorities. He knew of no instance of an electric tram crossing a railway on the level.

Mr. STEPHEN SELLON said the length of the tramway in this bill was 20 miles and its estimated cost £136,000. It was intended to carry every possible class of goods which could be laid hold of—to make the line common carriers all over the district to the various railway stations. As the handmaid of the railway companies, the tramway would be of great assistance in distributing goods between the railway stations and the various towns, from which the stations were some distance. There would also be considerable local traffic arising from local industries such as iron smelting, brick making, boot making and coal carriage. Protection was given to the London & North-Western Railway Co. by clause 9 of the bill, under which these tramways could not be constructed without the consent of the railway company; but there was a provision that if they refused their consent they should, in the event of the tramway company constructing the remaining portions of the tramroads, afford reasonable facilities for the exchange of traffic at the cost of the tramway company, and if any difficulty arose it should be determined by arbitration in the

Digitized by Google

usual manner. The effect of that was that the tramway company could not make trams within the bounds of the London & North Western Company; but that if they made the outer portions they could require the railway company to give reasonable means of interchange at the stations. As to the level crossing at Wellingborough station, the proposal was simply to lay the line in a road which already crossed the railway lines. If the railway company's objections were sustained it would mean that all light railways or tramways in the district would have to provide bridges at serious expense, which would go far to prevent the development of schemes of this nature. A bridge was not necessary, and he was quite unable to appreciate the argument of the railway company that there would be danger. There were plenty of cases of tramways crossing a railway on the level. A man in the signal box at the level crossing could see the whole country round, and thus know when a train or car was approaching.

Mr. COOPER, C.E., gave similar evidence.

Mr. LITTLER, Q.C., for the London & North Western Railway Co., said that if the present proposal were sanctioned, it would be quoted in support of similar proposals in respect of many other level crossings on their system. The promoters were going to make the profit from the scheme, and they should bear the cost of making the bridge which was required to carry the scheme out. It was said that the railway company would be safeguarded because the regulations for the crossing would have to receive the approval of the Board of Trade; but the Board of Trade could only make such regulations as were consistent with the running of the trams,—to which the railway company object. The proposal to run into the railway company's yards was an audacious one, because it was an interference with the private property of the railway company; and if assented to would open all the company's stations to speculators who might desire to save themselves the cost of purchasing land alongside stations. If the tramway company wanted to come to the railway, let them buy land alongside; and if they could not or would not do that, they should trust, as omnibus and cab proprietors trusted, to the goodwill of the railway company. The railway company were not opposed to the tramway scheme, and if the bill were passed would give the tramway company such facilities and access to the stations as were reasonable; but they strongly objected to this compulsory power. If the railway company did not give them reasonable facilities the tramway company could always apply to Parliament for relief. As to the crossing of the railway company's main east and west line on the level, surely they were entitled to the protection of a bridge, which would add little to the whole cost of the scheme.

Mr. TURNBULL, superintendent of the London & North-Western Railway Co., said there was the strongest possible objection to any railway crossing another railway on the level; and in this case the tramway was practically a railway, for they proposed to carry goods. All the danger which attached to the crossing of one railway by another attached to the crossing of the railway line by the electric tramway; in fact, in this case the danger was greater because, whereas in the case of two railways crossing there was an elaborate system of block sections to protect each of the trains coming from the four directions, in the present case there would not be that protective system. Further, the man in the signal box at the crossing would not have a good view of the train coming from Irchester because the line turned a corner just before approaching the railway.

Mr. FRANCIS STEPHENSON, engineer-in-chief to the London & North-Western Railway Co., said in some places level crossings could not be avoided, but where possible they should be avoided; and therefore the proposed level crossing in this case should be avoided, as might easily be done, by a bridge. The gradient of the road towards the crossing was about 1 in 28, and therefore, if the rails were greasy, quite possibly a tram might run through the railway gate when they were closed.

Major-General HUTCHINSON, for 28 years an inspector of railways under the Board of Trade, said during the latter part of his career one of his special duties was to report on level crossings. It was absolutely unknown for railways in these days to cross on the level; and of late years everything possible had been done to discourage the crossing of a road on the level. Such crossings were only recommended for adoption where local and other considerations rendered them desirable. All level crossings were dangerous, admittedly; if a railway line was crossed on the level by a horse tramway it tended to increase the danger, and if the tram was worked electrically it still further increased the danger. An electrically worked tramway was to all intents and purposes a railway. If from any cause the driver of an electrically or mechanically worked car became incapacitated or lost control of the car as it approached the railway when the gates were closed the car would dash through them, whereas horses would stop almost of themselves against the gates. Then, when trains crossed on the level there was a system by which trains were prevented from approaching the crossing-place while one was passing there, but that was not the case with tramways. A similar case to the present was before Parliament in the Grimsby Tramways bill, and was rejected.

Mr. J. L. WILKINSON, general manager of the Great Western Railway Co., gave similar evidence.

Mr. WORSLEY TAYLOR, Q.C., for the promoters, pointed out that the contention of the railway company in this case amounted to this, that simply because there was a level crossing in a bill the scheme should not be sanctioned. There was no general rule that level crossings were not to be allowed. For about 21 hours of the day the gates at the level crossing were open to all classes of traffic. A traction engine drawing a number of trucks could cross the lines at any time that the gates were open, and it was absurd therefore to say that the tram drawing probably two cars should not cross. The answer to the contention that a bridge should be erected to take the tramline over the railway was that the local authority did not want it because they recognised that it would be a mistake to have a gradient on a tram route like this. As to the tramway running into the Wellingborough and Higham Ferrers stations on the London & North Western Railway, that company were given protection which in similar cases had satisfied the Midland Railway Co.

The chairman said the Committee found the preamble of the bill proved, but disallowed the two portions of line giving access to the two stations on the London & North Western Railway, and allowed the level crossing.

READING CORPORATION TRAMWAYS BILL.

On June 21 the Reading Corporation Tramways bill came before a Select Committee of the House of Lords, presided over by Earl Erne.

Mr. PEMBROKE STEPHENS, Q.C., for the promoters, said the bill provided, amongst other matters, for the introduction into Reading of the modern system of electric tramways. The horse tramways, in Reading were owned by a company which obtained its powers in 1878. In 1899 the Corporation obtained authority to extend the tramways and the use of mechanical power generally; and the present bill was for a further extension. The existing line was 2½ miles in length. Under the company's Act of 1878 the Corporation had power to purchase within a shorter period than that authorised by the general Act of 1870. The contention of the company was that having failed to purchase within that shorter period the Corporation could not now purchase at all, because by the Act of 1878 the Corporation varied the provision of the general act as to period of purchase, and they had not acted in accordance with that variation. The same point arose in the case of the Wallasey tramway and the Wallasey District Council. Mr. Justice Ridley, in that case, held that the contention of the company was correct, but the Court of Appeal decided the other way, and an appeal was now pending to the House of Lords. If the House of Lords agreed with the first court, the Corporation of Reading could never purchase at all; consequently the company held that the Corporation should not have the powers sought in this bill, which must have the effect of injuring the tramway company if they could never purchase. Counsel urged that the company were trying to raise some legal point which, if raised at all, should be raised elsewhere. Continuing, he said running powers were authorised over the company's lines as soon as the proposed lines of the Corporation, five in number, were constructed. These new lines were greatly needed, and would be of real public advantage, and in any case would not affect the tramway company in the least, except at the points of junction. The only opposition other than that of the company to the tramways portion of their scheme was by Messrs. H. & G. Simonds (Ltd.) and others, who alleged that part of the route was too narrow, that the trams would interfere with their business, and be dangerous.

Mr. HENRY DAY, town clerk of Reading, in supporting the bill, went into the history of the tramways, pointing out that as late as last year, in certain objections made to the Board of Trade, the company recognised the right of the Corporation to purchase under the general Act of 1870, statutory notice was given in proper form to purchase under that act, and was followed by a writ from the company against the Corporation proceeding with the purchase. That case was now pending before the Courts. The contention of the Tramway Company was that inasmuch as the Corporation had varied the language of the general Tramways Act, and did not purchase under the terms of that variation they could not purchase at all.

Mr. COWARD said all he wanted to do was to preserve the *status quo*. Even if the House of Lords restored the decision of Mr. Justice Ridley, the effect of this bill would be to give powers to the Corporation to construct tramways which might injure the company.

Mr. W. B. MONK, chairman of the Tramways committee of the Reading Corporation, said the Corporation had for years desired to purchase the tramways, but had decided to wait till they could do it at old-iron price. The power sought was to make a north and south and a supplementary east and west system, and to couple with it the trams proposed to be acquired from the company.

Other evidence having been given,

Mr. STEPHEN SELLON said the scheme was a good one and there would be no engineering difficulty in construction, or in running the trams by electricity. As to the crossing he could give no case of two opposition lines crossing at right angles; but there were a number of cases in which lines crossed in that way. There would be no difficulty in lines in either case so crossing.

Mr. G. W. PALMER, M.P. for Reading, generally supported the scheme.

Mr. JOHN BOWEN, borough engineer and surveyor of Reading, said there had been a growing feeling that something better than the existing horse tramways on single lines with passing places was needed. The present proposal would add a north and south system to the existing east and west system and would be worked with the most modern electrical equipment. The estimate for the electrical equipment, trams, and works, &c., was £135,000, which would provide power sufficient not only to work the tramways in this bill, but the Corporation tramways authorised in 1899, and the tramways of the company when they became the property of the Corporation.

Mr. J. KINCAID (Messrs. Kincaid, Waller & Manville) said the tramway scheme was well laid out and would be advantageous to the town.

Mr. I. WINSLOW gave evidence as to the suitability of the electric system proposed. The overhead trolley system, which the Corporation had adopted, was well adapted to the requirements of Reading. There was no electrical or engineering difficulty in working or constructing a line worked by electricity which crossed a horse tramway.

This closed the case for the promoters, and evidence having been given on behalf of the frontagers,

Mr. LEWIS COWARD, on behalf of the tramway company, submitted that until the House of Lords had given their decision in the Wallasey case—the legal principles involved in which were identical with those in the present bill—it would only be right and fair that the Committee should

Digitized by Google

give a clause to the company, protecting them in the event of the Corporation never being in a position to purchase the tramway undertaking. He asked for a clause similar to that inserted in the Tramways Order Confirmation Act, obtained by the Corporation in 1899, to the effect that nothing in the Act should authorise the interference by the Corporation with any of the lines of the tramway company until the tramway undertaking had been actually purchased and taken over by the Corportion. It had been admitted that two tramways, worked electrically, crossing each other at right angles, in different hands, must be not only a source of considerable interruption to the traffic of both systems, but of real danger to the public. Hence the necessity for the clause.

Mr. PEMBROKE STEPHENS, for the promoters, offered the tramway company, in place of the clause suggested, the ordinary junction clause.

The CHAIRMAN announced that the Committee found the preamble of the bill proved, They thought, however, the river opposite the brewery, and near the site of the proposed generating station, should not be narrowed; and with regard to No. 2 tramway (the Bridge-street main proposed route), they held that the ordinary junction clause offered by Mr. Pembroke Stephens would be sufficient.

Subsequently the clauses were adjusted, and the bill ordered to be reported.

WESTON-SUPER-MARE TRAMWAYS BILL.

On Wednesday the House of Commons Committee, presided over by Mr. de Tatton Egerton, considered the bill to confirm the provisional order granted by the Board of Trade authorising the Weston-super-Mare and District Electric Supply Co. (Ltd.) to construct some 3 miles of tramways at Weston, to be worked by electricity on the overhead trolley system.

Mr. J. C. GRAHAM, for the promoters, said the only opponent remaining was the Commercial Cable Co. That company alleged that the current leakage from the tramways would prevent the reading and proper working of the delicate recording instruments in use at their cable station at Weston. The answer of the tramway company was that the whole question had been considered by a Committee of Parliament in 1893 in the case of the telephone companies, who had for a long time opposed all electric tramways. Before that Committee it was proved that the telephone company could entirely get rid of interference by the adoption of metallic returns. That Committee had reported against compelling tramways to use insulated returns. Interference with telegraph cables, such as was now referred to, had occurred at Coney Island, New York, but in that case it was got rid of by running a wire to earth some 2 miles out at sea outside the area of interference. The same kind of interference had been neutralised at Capetown by laying a second cable parallel to the existing one for some miles out to sea. The promoters said that the obvious remedy in this case was for the cable company to do what had been done with success in other cases.

Mr. J. E. NORMAN, vice-chairman of the District Council, and of the Electric Lighting committee of Weston, said his Council were unanimously in favour of the proposed tramways, which were much needed.

Mr. STEPHEN SELLON, C.E., said the Commercial Cable Co. could protect itself from these electric leakages by the adoption of twin core cables. When the first electric tramway was laid down at Leeds it was found that the whole telephone system was affected, and an action was brought against the Leeds Corporation, which failed. Since that time the telephone company had put up a service of metallic returns. The proposed tramway would pass along the sea front, and the conduit system would be objectionable there, as at Blackpool it had been found that the sand and water so affected the working as to cause frequent stoppages. He considered the expense of a double trolley insulated return system would be too great in the present case, and he should not advise the construction of the tramways under such conditions.

Mr. H. M. SAYERS, said that although a twin-core cable would obviate interference from the tramways, it was difficult to say how far the double cable would have to be carried out to sea. If the strata were a good conductor it would extend the area of disturbance. On the other hand, the earth round the tramway might be a good conductor and the outlying strata a bad one. The shape of the tramway and its position in relation to the line of the cable and the position of the sea were all factors in the question of disturbance. In this case the line of tramway would give rise to the smallest amount of interference. It was not practicable either theoretically or commercially to have insulated returns on this tramway. All conductors negative to the rail leaked much more than the positive, and caused disturbances. If the surface-contact system were adopted there might be less interference than with the rail return.

This evidence closed the promoters' case.

Mr. GEORGE G. WARD, vice-president of the Commercial Cable Co., said the cable at Weston was worked nearly all the 24 hours. Three-fourths of the messages received at the cable station in Ireland came on to the Weston cable, which was the most important cable owned by his company. Another cable from Ireland was about to be landed at Weston. By the expenditure of money his company might protect the cable from disturbance, and the tramway company by spending money might also prevent their system doing the Commercial Company any injury. There was some doubt, to his mind, as to whether his company could efficiently protect the cable. This company had found a current of 25 volts 4 miles or 5 miles out to sea in the case of their cable at New York, caused by the electric tramways. Even if they moved their cable station from Weston, which would be most expensive, there would be no assurance that they would not suffer from disturbance. The instruments used by his company were very delicate, and even a small tramway like the present would release enough electric current to seriously disturb the instruments.

Mr. J. GOTT, chief electrician to the Commercial Company, said the cable at Coney Island was a four-core one. Two cores were used for working the cable and two cores for neutralising the leakage disturbances. The cost per mile of carrying a twin-core cable out to sea would be £600. No case of interference with cables from electric traction had yet arisen in this country. The interference arose both from induction and direct transmission of currents into the cable. If the tramway were sanctioned it might even be necessary to protect the cable for 100 miles.

Mr. H. A. C. SAUNDERS, electrician-in-chief to the Eastern & Associated Telegraph Companies, agreed that the proposed tramway would be detrimental to the working of the Weston cable. What had happened at Capetown, where the positions of the tramway and the telegraph cables were somewhat similar, was that the cable had been doubled—first for 5 miles, and then 10 miles, and eventually for 40 miles out to sea—which had to a certain extent overcome the difficulty. He had no doubt as to the certainty of the tramway now proposed affecting the cable.

Yesterday, Mr. JAMES SWINBURNE said in the present case it was impossible to say how great the disturbance would be to the telegraph cable; they could only judge by what had happened in other cases. The remedy for the disturbances was to run a return circuit out for some miles to sea. It would not be fair to ask for compensation for an indefinite number of miles. The Commercial Company's cable was a short one, about 350 miles in length, and the signals used upon it could be stronger ones than in the case of a longer cable. The cost would be about £1,000 per mile to carry out a second cable to sea. The question here was, who was to pay for this cable and its laying. The Committee of 1893 did not consider the question of cables in relation to disturbance by electric tramways.

Prof. W. E. AYRTON said that from his experience in relation to other submarine cables, the chance of disturbance would be very great. He said that with a knowledge of the working of the cables at Weston, and what had occured at Capetown. A tramway could be so constructed with insulated returns that there would be no risk of disturbance, but perhaps the tramway in this case could not bear the expense. The laying of a twin-core cable end to the telegraph cable at Weston was perhaps the simplest way of obviating the disturbance.

Mr. PEMBER, Q.C., for the Commercial Company, said there could hardly be a more important public interest than the protection of telegraph cables against disturbance. The promoters admitted the probable disturbance, and the only question was who should pay the cost of remedying that disturbance. He asked the Committee to insert a clause that if the promoters constructed this tramway the Commercial Company should be allowed to carry out any works necessary to prevent disturbance at the expense of the tramway company, with reference if necessary to an arbitrator to be appointed by the Board of Trade.

Mr. BALFOUR BROWNE, Q.C., for the promoters, said that what was being now attempted in the matter of submarine cables had been attempted before in the case of telephones, and had had for the time the effect of stopping the tramway industry. But Parliament had interfered, and while giving a certain amount of protection to telephones, and compelling the tramway companies to stop leakage where possible, had otherwise left the telephone companies to protect themselves by metallic returns. Bristol was not far from Weston and was extending its electric tramways, and a tramway was coming into Weston. The Commercial Cable Co. were now seeking to protect themselves from all these at the expense of this small undertaking. They had no protection granted them on the American side, and there was no reason why it should be granted here. If it was, Parliament would again have to interfere to prevent the crushing out of these small tramway enterprises.

The Committee adjourned, postponing their decision.

PLYMOUTH, STONEHOUSE AND DEVONPORT TRAMWAYS BILL.

This bill came before the House of Commons Committee on Unopposed Bills on Monday. The object of the bill is to confer further powers upon the Plymouth, Stonehouse and Devonport Tramways Co., which seeks power to construct double lines of tramway in Plymouth and Stonehouse to a gauge of 3ft. 6in. and to work these and the existing tramways of the company by electric power. The period assigned for the completion of the works is three years. The preamble was proved, and the bill was ordered to be reported.

SOUTH LANCASHIRE TRAMWAYS BILL.

The Leigh Rural, the Tyldesley, Atherton, and Westhoughton Urban Councils, and other local authorities in the Manchester and Wigan districts have been informed by their Parliamentary agents that practically the whole of their protective clauses in this bill, which were inserted by mutual agreement with the promoters, have been struck out by Lord Morley, the chairman of Committees in the House of Lords. At a conference on Monday it was decided to appoint a deputation to wait upon Lord Morley with a view to securing the clauses, which relate principally to road widenings, failing which the Councils will oppose the bill and endeavour to throw it out.

CAMBORNE AND REDRUTH TRAMWAY BILL.

On Wednesday, the Committee of the House of Lords, of which the Duke of Northumberland is chairman, commenced the consideration of this bill.

Mr. ERSKINE POLLOCK said the bill was promoted by the Urban Electric Supply Co. (Ltd.) to construct tramways from Camborne, passing through Illogan, to Redruth. It would be 3 miles 3 furlongs in length, 2 miles 6 furlongs being single line and 5 furlongs double line, and the gauge would be 3ft. 6in. The motive power was electricity, and the system proposed to be used was the overhead or trolley. The trams would run along the main road between Truro and Penzance to the centre of the town of Camborne. The population of Redruth was 10,000, of Camborne 14,000,

Digitized by Google

and of the intermediate district over 9,000, and the tramway would meet a great want in the neighbourhood. The only opposition came from the Great Western Railway Co., who ran eight trains daily each way between Camborne and Redruth. Tramway traffic was essentially pick-up traffic, and while the line would doubtless do some injury to the railway in some respects it would prove a feeder. The opposition of the railway company was on the ground of competition. They alleged that the service of trains run by them was sufficient to meet the needs of the traffic.

Yesterday the Committee found the preamble proved.

Mr. MOON, on the consideration of clauses, asked that as the tramway company's line crossed the line of the Great Western Railway Co. on the level, in the interests of the public the promoters ought to pay for any additional cost incurred by the railway company in consequence of the passing of the bill. The Board of Trade might direct that the railway company should put up additional signals in consequence of the tramways crossing the line.

Mr. ERSKINE POLLOCK contended that the provisions of the general law covered the case.

The Committee decided against Mr. Moon's proposed clauses.

MUSSELBURGH ELECTRIC TRAMWAYS BILL.

Opposition has been withdrawn, and the bill will now proceed as an unopposed measure.

BRAY AND ENNISKERRY RAILWAY BILL.

This bill came before a Select Committee of the House of Commons, presided over by Mr. de Falton Egerton, on June 20. The object of the measure is to empower the Bray and Enniskerry Railway Co. to make extensions of their authorised lines in the counties of Dublin and Wicklow, and to work the same and the railways authorised by an Act of 1886 by electric power; to raise £25,000 additional capital by shares and £12,500 by loan; to extend the time for the completion of the railways authorised by the Act of 1886, and to empower the company to enter into agreements with the Bray District Council and the Dublin, Wicklow & Wexford Railway Co. The Wicklow County Council suspended their appearance, it having been stated that the promoters agreed to insert a clause protecting their rights as the road authority, and to lodge £1,000 in the bank as security for the completion of the line.

Mr. Worsley Taylor, Q.C., represented the promoters; Mr. Littler, Q.C., the Dublin, Wicklow & Wexford Railway Co., who opposed, and Mr. Pembroke Stephens, Q.C., the Earl of Pembroke, who also opposed.

After hearing the evidence,

The CHAIRMAN said the Committee found the preamble proved so far as related to the extension of time for the completion of the original line from Bray to Enniskerry, and so far as related to the new branch from Bray to Bray Harbour; but declined to grant the proposed extensions to Hollybrook and Scalp.

Protective clauses were inserted for Earl Pembroke and the railway company, and the promoters were ordered to lodge £1,000 with the National Bank at Wicklow as security to the County Council for the completion of the line and the re-instatement of the Council's roads.

THE ELECTRIC POWER BILLS.

The Select Committee of the House of Commons on Electric Power Bills resumed, on Friday last, its investigation into the South Wales Power Bill. Sir J. Kitson presided.

Mr. PEMBER, Q.C., continuing his opening speech for the promoters, said his clients sought nothing more than the right to trade in the ordinary course of commercial competition in the business of electrical supplies, and did not seek to prevent local authorities or anyone else competing with them. As to the districts already supplied they would restrict their business to dealing with the local authority except in regard to customers for whom the local authorities did not attempt to cater, and for whom they would never be able to cater. He then referred to the restrictions imposed by the Board of Trade on electric supply companies, and, in illustration, produced specimens of two kinds of cable—one the overhead cable used by the Niagara Co., and made at Providence, U.S.A., and the other the kind of cable that was to be used by the South Wales Co. The first, he said, cost £700 a mile, and the second, under the restrictions of the Board of Trade, £2,000 a mile, and yet the first did over three times the amount of work done by the second.

Mr. E. H. REECE said he wished to give evidence in place of his partner, Mr. Porter Brown. His firm acted as agents for many large colliery owners in the South Wales district, the total output of the collieries at present under their control being 2,000,000 tons per annum. At the present moment the question of the cheap production of coal was exercising the minds of everybody in the district, the more cheaply worked seams being now exhausted. He understood that the promoters of this bill would provide power at from £4 to £10 per H.P. per annum. It was costing at present more than that at the collieries, and if only a portion of the power used at the collieries could be obtained at a cheaper rate it would make a considerable difference in the actual production of coal and would simplify the problem of working the more costly seams. Some of the collieries had already electric installations, but only for lighting. The capital of the undertakings represented by the promoters of the company was nearly £23,000,000, and they were interested in pretty nearly all the large works in the district. He admitted that if the company spent £50,000 on the undertaking they would have the right to supply the whole area. They would not, however, ask for powers unless they did intend to supply. The bill provided that the company would not supply within the area of any local authority without the consent of the local authority. There was a sliding scale clause in the bill so that the company would only be able to increase their dividend when they reduced the charge for electricity to 2½d. per unit. He did not know that the second readin of the bill in the House of Commons was obtained by the promoters accepting the undertaking of the President of the Board of Trade that they would not supply within the district of any local authority without the consent of such authority.

Mr. RAM, Q.C., for the promoters, said that as soon as it was found that Mr. Ritchie had made the statement referred to the promoters waited on him and said they could not agree.

WITNESS (continuing) said he did not think the operations of the promoters would ruin the Pontypool Electric Lighting Co., but if the promoters supplied more cheaply than that company the public of course would benefit. He did not see why a company should be protected from the effects of competition. Electric power could be used in collieries for lighting, pumping, and hauling. In a large colliery as much as 1,000 H.P. could be used for hauling purposes alone. The charge under the bill was to be £10 per H.P. per annum at the outside, while the promoters hoped that it would not exceed £4. Under present circumstances £15 per H.P. was the cost of fuel alone, so that he anticipated that in a colliery raising 750,000 tons of coal there would be a saving of £10,000 a year. He was of opinion that the development of electric energy in the district was behind the times, and he did not think that the local authorities contemplated supplying electric energy except for lighting. As he objected to local authorities engaging in trade, he did not blame them for having neglected to provide power.

Mr. CORBETT, surveyor of the South Wales estates of the Marquis of Bute, said there were enormous industrial works at Cardiff, and most of them needed steam power. It was only the largest undertaklngs that could afford to provide electric installation of their own, and he thought there was little chance of the Corporation of Cardiff supplying electricity for power purposes. Even if they did, he doubted if it would be possible for them to do so as cheaply as the company. The Corporation, of course, having to safeguard the ratepayers' money, could not be as speculative as a company. He considered it essential the bill should provide for lighting as well as power, and thought that a limited competition with local authorities would be a wholesome stimulus. The Cardiff ratepayers had recently declined to allow the Corporation to extend electric tramways into the outside areas.

Mr. JENNINGS, timber merchant, Cardiff, said if timber merchants could obtain electric power they would be able to insure their yards and stocks at a much lower rate than at present. He did not know Cardiff Corporation had offered to supply electric power at 2d. per unit for 4,000 units, and 2½d. per unit for smaller quantities, but he saw from the local papers that they could not generate enough current for lighting.

Mr. ANDREW, Chairman of the Cardiff Chamber of Commerce, said that body had passed a unanimous resolution in favour of the bill.

Mr. E. P. MARTIN, manager of the Dowlais Iron Co., and a director of several large colliery companies, said he was anxious to obtain electric power both in the collieries and in the ironworks. He considered it necessary that manufacturers and traders in South Wales should have such a power in order that they might compete effectually with the foreigner.

Sir J. GUNN, director of many large colliery and other companies in South Wales, considered it important that a good and cheap supply of electric power should be forthcoming, and that the local authorities would hardly be justified in putting down plant sufficient for such a supply.

Mr. G. W. WILKINSON, director and engineer of the United and National Collieries (Ltd.), declared that the company would be very glad to get such a supply of electric power as would be obtainable under the bill. Electric power would be admirable for driving drilling machinery, and he believed it would enable colliery proprietors to work small seams of coal which could not be at present worked at a profit. He thought it would be possible in time to use electricity as an explosive and for hauling and other colliery purposes.

Mr. MAURICE DEACON, mining engineer, said steam and compressed air were the chief sources of power at present in use in mines, and the transmission of the power from the engines was managed by means of compressed air, electricity and hydraulic power. It would be very costly for individual manufacturers to supersede the present method by the adoption of electricity entirely. There would not only be the cost of installation but the old plant would have to be abandoned. He believed that the cheapest method of supplying electricity was by establishing generating stations over a large area, though very large mines could supply themselves economically by having installations of their own. Something must be done, and done quickly, to meet the very serious foreign competition now threatening the South Wales industries, and in the general use of cheap electricity he saw a means to that end.

Mr. T. CALLENDER said the solid system of laying electric mains was the one almost universally adopted. He regarded the provision in the bill empowering local authorities to break up the streets and lay the cables as affording sufficient protection to local authorities.

Mr. H. GRAHAM HARRIS (Messrs. Bramwell & Harris) thought the company would be able to carry out their undertaking throughout South Wales. He considered that the "brand" of electric current supplied by the Cardiff Corporation though suited for lighting was unsuitable for power.

On Wednesday Mr. BALFOUR BROWNE, Q.C., for the Corporations of Cardiff, Swansea, Newport, and Barry, contended that the South Wales district was unsuitable for a scheme of this kind, as there was plenty of steam coal with which the collieries could produce power more cheaply by electricity. Under one of the clauses of the bill a town like Barry would be deprived of its right to set up a generating station, and would be compelled if it supplied electric power at all to purchase current from the company in bulk. Consequently, if the Corporation could manufacture electricity more cheaply than the company it would not be allowed to do so.

Digitized by Google

The CHAIRMAN: The Committee think the time has arrived when it would be convenient for them to make a declaration. Sir J. Kitson then read the following statement:—

"A local authority which undertakes and is prepared to give a full "and ample supply of electrical energy for all purposes to consumers "within its district ought not, without its consent, to be required to "give facilities for the supply within its district of electrical energy "by other undertakers. But if a local authority is unable or unwilling "to provide, on reasonable terms and within a reasonable time, a full "and adequate supply of electrical energy for any purposes to any "company or person applying for the same within its district, such "company or person should be at liberty, after notice to the local "authority, to obtain their supply from other authorised undertakers, "and the local authority should be required to give all necessary "facilities for this purpose. Any difference arising out of the above "questions should be the subject of arbitration, as provided by the "general acts."

Sir James Kitson added: Of course this overrides the clause providing that in any event the company shall be at liberty to supply to any person within such area as is willing to undertake to receive a supply of not less than 20,000 Board of Trade units per annum.

Mr. BALFOUR BROWNE said in view of the Committee's decision he would close his case and concede the preamble.

Counsel representing other local authorities took a similar course.

Evidence was then given in support of the petitions of the Venarth and Pontypool electric lighting companies.

Yesterday Mr. WEDDERBURN was allowed to speak on behalf of some of the smaller local authorities. He pointed out that Tredegar and Ebbw Vale were partly in Brecknock and partly in Monmouthshire, and would therefore have to be specially dealt with. He also drew attention to a circular issued by the South Wales Electrical Power Distribution Co. in which they stated that they did not intend to deal with electric lighting, and said that if the Committee allowed lighting powers to remain in the bill it would permit the company to break faith with those who had acted on the circular. He hoped the Committee would agree to make clearer the provisions in the bill as regarded consent of the local authority and supply in bulk.

Committee's Decisions.

The CHAIRMAN said:

"I have to announce that the Committee are of opinion that, subject "to the principles contained in their declarations being embodied in "clauses to be approved, and subject to such additions to and amend-"ments in clauses . . . . as on going through the clauses of the "bill appear necessary, the preamble of the South Wales Electrical "Power Supply Bill is proved. It may be convenient, though the "business is not down for to-day, to announce that the preamble "of the Durham Electric Power Supply Co.'s Bill is proved, that the "preamble of the Tyneside Bill is not proved to the satisfaction of "the Committee, and that the preamble of the Lancashire Electric "Power Bill is proved to the satisfaction of the Committee. The "intention of the Committee is to insert, as far as may be applicable, "the same conditions in each of the bills."

The Committee then adjourned until Tuesday, when the clauses of the bills will be considered.

ELECTRIC LIGHTING ORDERS.

The bill to confirm the Electric Lighting Provisional Order (No. 9) came on Tuesday before the Select Committee of the House of Commons presided over by Sir A. Godson. The bill was to confirm five orders, but the only orders opposed were those referring to the Isle of Wight and Gosforth (Northumberland).

THE FRESHWATER ORDER.

The first order considered was the Freshwater and Totland Bay order. This was an order of the Board of Trade under the Electric Lighting Acts of 1882 and 1888, empowering a company to construct works and supply electricity in the districts of Freshwater, Totland Bay, Yarmouth, and the Isle of Wight.

Mr. RIGG, for the promoters, called

Mr. C. EDMUNDS, solicitor, a director and present secretary of the proposed company, which, he said, was formed in March last to supply the district. Except at Yarmouth, where there was a small gas works, there was no system of lighting at all. The capital of the new company would be £15,000, with borrowing powers of £5,000. There would be five directors, who were all residents. Since the provisional order was issued the circumstances had somewhat changed. The period for the purchase of the undertaking by the local authority had been fixed by the Board of Trade at 42 years; but in the case of Bonchurch the period had been fixed at 7, 14 and 21 years. In this case, however, current was supplied from Ventnor, Bonchurch having no independent generating station.

Mr. FRANK CHRISTIE (Messrs. Christie Bros. & Middleton, Chelmsford) gave details of the equipment of the undertaking, which he considered would be a successful commercial speculation. They had secured a site close to the station with a siding from the railway, where there was a good supply of water. They would instal a plant capable of supplying 3,000 8 c.p. lamps at a cost of £10,000. They estimated that the first year they would supply from 1,200 to 1,500 8 c.p. lamps, which would about pay the expenses and leave a small margin. When they got a supply of 3,000 lamps they would be able to pay a dividend of 5 per cent. They could double the plant at a cost of £5,000, and could then pay a dividend of 10 per cent. The charge for current would be 7d. per unit, which was less than the usual charge in places of like population.

Mr. WEDDERBURN, Q.C. (for the District Council of the Isle of Wight, who opposed, but called no witnesses) said when the order was promoted Freshwater was only a rural district, but since that time it had become an urban district, and as such would be able to get a loan for electric lighting from the Local Government Board. They thought, therefore, they should not be debarred by any grant to the company from exercising their rights. He asked, in any case, that the period of purchase should be reduced to a maximum of 21 years; that the price for current should be reduced from 7d. to 5d., and that they should have some security beyond the deposit of £500 for the Company going on with the works.

The Committee found the preamble proved, but reduced the period for the purchase from 42 years to 21 years, with a premium of 15 per cent. above the value, 28 years with a premium of 10 per cent., or 35 years with a premium of 5 per cent.

THE GOSFORTH ORDER.

This was a Board of Trade provisional order empowering the Newcastle-on-Tyne Electrical Supply Co. (Ltd.) to extend their area and supply electricity in Gosforth. The only opponents were the Newcastle Corporation.

Mr. MOON, for the promoters, said the company was formed in 1889, and in 1890 erected their present generating station at Pandon Dene. At that time there were very few houses near but with the growth of the town building operations had been carried on, and the Corporation objected to any increase of the station. But the company were proposing to take an area of land outside the town, near the Tyne, on which to erect a generating station. The Council objected also to the interference with their streets in the company's carrying their mains to Gosforth, but it was now generally held that a company had the right to pass through the roads of any public authority for the purpose of supplying a district beyond. Dr. Merz, a director, and Mr. W. M. Harris-Burland, engineer of the company, gave evidence in support of counsel's statement, and after consultation an arrangement was arrived at by which the Corporation withdrew their opposition.

Yesterday a clause was brought up to protect the rights of the Corporation as to the route of the cable through the city, and the bill was ordered to be reported.

WEST HAM CORPORATION BILL.

The Select Committee on Police and Sanitary matters, presided over by Mr. Reginald M'Kenna, last week considered the bill of the West Ham Corporation, which empowers the Council to enlarge the present electric generating station, to acquire and work by electricity several lines of tramways, &c., at an expenditure in all of nearly £900,000.

Mr. BALFOUR BROWNE, Q.C., for the Corporation, said West Ham was a rapidly growing place, and at present the population was estimated at 310,000. The only opposition to the tramways portion of the bill was that of the North Metropolitan Tramways Co., the point raised being as to the portion of the company's undertaking the Corporation desired to purchase. The present tramways in the district were two—one from Bow to Wanstead (the lease of this portion had expired, and an arbitration was now pending as to what the Corporation had to pay); the second was from Stratford to East Ham, the lease of which would expire in 1904. The Corporation were endeavouring to arrange for the purchase of this undertaking at once. The estimated cost of the tramways would be £210,000, and the whole were to be electrically equipped.

Mr. JOSEPH WALLER (Messrs. Kincaid, Waller & Manville) detailed the proposed lines, which would be of great service in bringing people from the docks to the centre of the town and from the centre to the country. The tramways would be worked in connection with the proposed lines of East Ham, and would become an important system. Notice had been given to purchase so much of the undertaking of the North Metropolitan tramways as was in their district. As soon as the price has been decided by arbitration, the Corporation would be able to take over that portion of the North Metropolitan system, but until 1904 they would not be in possession of the remainder. The overhead system of electric working could be adopted.

The Committee ultimately passed the tramways portion of the bill, and the bill was ordered to be reported.

DUBLIN ELECTRIC LIGHTING BILL.

In the House of Commons on Tuesday, on the motion for the consideration of this bill, Mr. CAREW moved: "That the bill be considered this day three months." He maintained that if the bill passed, it would be the first time that a private company had been allowed to enter into competition with a local authority. The Dublin Corporation had power under a provisional order to supply electricity, but having spent £89,000 in plant and exhausted their borrowing powers the service had not been satisfactory. They had recently, however, obtained new borrowing powers, and the Local Government Board had sanctioned an electric lighting scheme which had been prepared for them by a competent engineer. Parliament ought not therefore to allow a private company to come in and compete with the Corporation.

Mr. BROWN, chairman of the committee which considered and passed the preamble of the bill, said it was proved that for many years past the Corporation of Dublin had had power to generate and supply electric current for lighting, and had failed to do so. If the Corporation had done their duty there would have been no case for this bill. As they had failed in their duty, the Committee thought it reasonable and fair that a new company should be allowed to enter into competition with the Corporation and to supply this great want to the citizens of Dublin and to some of the out townships.

Mr. TREVELYAN, another member of the committee, said he differed so strongly from his colleagues that he took a division on the preamble of the bill. The House was asked by this bill to create an entirely new precedent. It had been the consistent policy of Parliament to refuse to

Digitized by Google

permit any private company to come in and compete in the matter of electric lighting in any town where the Corporation had undertaken the work and was unwilling to permit any private company to enter into competition. He contended that the Dublin Corporation had done their best under the circumstances. They had obtained power to borrow £250,000 to put stations all over Dublin. He believed if such a bill as this were proposed for, say, Glasgow, it would not be listened to.

Mr. T. M. HEALY said it was a remarkable fact that the people who were most anxious for a continuation of this monopoly in the hands of the Corporation of Dublin were the gas company. Why was the gas company so extremely anxious that this monopoly should remain in the hands of the Dublin Corporation? Because it knew well that the Corporation, having muddled away, with the assistance of the gas company, £100,000 of the ratepayers' money, would muddle away £100,000 more. Why should he pay as a ratepayer of Dublin 7d. for electricity which, if he lived in Cork, he could obtain for 3d.? The chairman of the tramway company, about which a good deal had been said, was formerly a member of the House—Mr. Murphy. What the House had not been told, however, was that the tramway company was paying the Corporation for this concession a rent of £12,000 a year and £300 per annum extra for every mile of tramway it made. He thought the Corporation had made an extremely good bargain for themselves. The Corporation had never taken any step to improve their position in the matter of electric lighting until this bill was brought in.

Eventually the motion for the consideration of the bill was carried by 13 votes, and with slight amendment, the bill was ordered for third reading.

CITY OF LONDON ELECTRIC LIGHTING CO.'S BILL.

This bill, which empowers the company to acquire lands for erecting additional generating stations, has now been sanctioned by a Committee of the House of Lords in the form in which it was amended by the House of Commons.

TELEPHONING TELEGRAPHIC MESSAGES.

In the House of Commons on Monday, Mr. HENNIKER HEATON inquired of the Secretary to the Treasury whether it was an instruction to postmasters throughout the country that they were not to forward telegraphic messages over the wires of the National Telephone Co.; and, if so, what was the explanation of the new policy exemplified in such an instruction?

Mr. HANBURY: The Postmaster-General does not now undertake to deliver telegrams by telephone to subscribers of the National Telephone Co. who may desire this privilege, but it remains to explain that this arrangement has not been withdrawn from any subscriber to whom it has been accorded in the past.

Mr. HENNIKER HEATON: When was this extraordinary new principle introduced?

Mr. HANBURY said the instruction had been issued because it was found that there were obvious disadvantages in the Post Office entering into what was practically a partnership arrangement with a private company, especially as that company was itself in direct competition with the Post Office and persistently refused similar facilities to Post Office subscribers.

LEGAL INTELLIGENCE.

Tramway Track Sanding.

On Tuesday and Wednesday last week, in the Queen's Bench Division Dublin (before the Lord Chief Baron, Mr. Justice Andrews, Mr. Justice Madden, and Mr. Justice Boyd) arguments were heard in the appeal of the Dublin United Tramways Co. from the decision of the divisional police magistrate (Mr. Swifte). Particulars of this case were given in our issues of Nov. 10, Dec. 1 and Dec. 10, 1899. The defendant company had to answer two summonses at the instance of the Dublin Corporation for having made default in maintaining and keeping in good condition and repair with such materials as the Corporation directed the tramway tracks within the city. On the hearing of the summonses by Mr. Swifte, fines of £5 and £10 costs in each case were inflicted. From the evidence submitted Mr. Swifte found that the tram tracks had not been maintained and kept in good condition and repair as directed by the Corporation, and had become, through their slipperiness, a danger and annoyance to the ordinary traffic. One cause of the slipperiness of the track was that in dry weather the "swishing" or brushing away of grit, gravel and dust lying on the tram tracks, which, if permitted to remain, would afford a certain amount of foothold to horses' hoofs, but which were "swished" away by the draught produced in the transit of electric cars over the track at a high speed. Mr. Swifte further found that to a small extent the slipperiness was caused by the setts or stones forming the tram track requiring to be re-dressed. He found, however, that defendants had made reasonable effort to keep the tram tracks re-dressed from time to time, and that their structural condition was fairly satisfactory. This latter was the only question of fact substantially controverted in the case, and he thus found it in favour of defendants. The proper remedy for the slipperiness complained of was, in his worship's opinion, the sanding of the tram tracks. Defendants raised a preliminary objection to his worship's jurisdiction to hear the summons founded on sec. 33 of the Tramways Act, 1870, and contended that under that section he should have sent the case to be settled by an engineer or other fit person nominated as referee by the Board of Trade; but he was of opinion that, even assuming that section to be applicable at all, as the main question in controversy was one of law—namely, the construction of the 28th section of the Act of 1870 and the 37th section of the Act of 1897—he had at least concurrent jurisdiction, and he convicted the defendants. The judgment of the Appeal Court was sought on the following points:—(1) Had the magistrate jurisdiction to adjudicate on the summonses? (2) If so, was he right in deciding that, on the facts so found by him, the defendants were guilty of the offence charged by having failed to comply with the provisions of sec. 28 of the Tramways Act, 1870, taken in connection with sec. 37 of the Dublin United Tramways (Electrical Power) Act, 1897?

The arguments against the magistrate's decision were delivered by Mr. Ronan, Q.C., and Mr. Gordon, Q.C.; and in support of the decision by The MacDermot, Q.C., and Mr. O'Shaughnessy, Q.C.

JUDGMENT.

Judgment was delivered on 14th inst., and by a majority the Court affirmed the magistrate's convictions.

Mr. Justice BOYD reviewed the Acts regulating the construction and maintenance of tramways in the city of Dublin, and held that the obligations cast on the company by these Acts had reference only to the fabric of the roads. It was not contended that the company had not constructed their lines in strict conformity with the statutes, or that they had not kept them in good repair. The words in sec. 37 of the Act of 1897, "Shall maintain in good order and repair, &c., so as not to be a danger or annoyance to the ordinary traffic," referred, according to his construction of the section, to structural works, wires, tubes, and electrical apparatus. The work which the Corporation could compel the company to do should be constructive work and nothing else. He thought it was to be regretted that the Corporation did not adopt the alternative provided by the section of the Act, do whatever work was necessary, and then sue the company for the cost. Had they done so the matter could be taken to a higher Court, but under the course that had been pursued there could be no appeal from the decision of the Queen's Bench. He was of opinion that the conviction should be set aside.

Mr. Justice MADDEN, in delivering the judgment of the majority of the Court, said the obligation cast on the tramway company by the Act of 1897 was obviously a duty with regard to the general public. Was a pavement that in certain weather became so slippery as to be a danger and annoyance to the ordinary traffic maintained in conformity with the statute, which provided that the tram tracks should at all times be maintained and kept in good condition, so as not to be an annoyance and danger to the ordinary traffic? So long as the roadway was a danger to themselves the tramway company sanded it, but when it only became a danger to the public they ceased to sand. The sections seemed to be for the protection of the public. He was of opinion that both convictions of the magistrate should be affirmed.

Mr. Justice ANDREWS thought the evidence of the chairman of the company was admissible, but as the magistrate said it would not have affected his findings, his disregard of it was immaterial.

The LORD CHIEF BARON concurred.

Washington & Co. v. Barraclough.

In the Chancery Division, last week, Mr. Justice Buckley heard an action brought by plaintiffs, manufacturers of electric cable-making machinery at Sowerby Bridge, against defendant, engaged in the same branch of industry at the same place. The parties had worked as partners. They had separately purchased certain patterns, drawings, &c., and agreed to work jointly, but disputes arose, plaintiffs contending that defendant had failed to produce proper accounts, and defendant alleging that plaintiffs had not paid him the proper proportion of profits due to him.

His LORDSHIP held that plaintiffs' version of the partnership agreement was the correct one, and directed an account to be taken on that basis. He also held that defendant had failed in his counterclaim for damages for alleged negligence by plaintiffs in manufacturing certain machines. Judgment for plaintiffs, with costs.

Telephone Rentals.

In the Westminster (London) County Court last week the National Telephone Co. sought to recover £18. 5s. for the hire of a telephone from the Transvaal and Australian Gold Concessions (Ltd.). The defence was that the Concessions received a letter from the company, stating that as the London County Council objected to underground wires and the Duke of Bedford to overhead, excepting upon very onerous terms, the National Company saw no prospect of being able to continue the service. The defendants therefore claimed that they were not responsible for the rent until after the year had expired; but Judge Lumley Smith, Q.C., held that, as the service was still supplied, and the defendants' contract with the National Company bound plaintiffs to return the money for the unexpired portion, they must pay, and he gave judgment for plaintiffs for the amount claimed, with costs.

In re the River Plate Electric Light and Traction Co. (Ltd.)

On Tuesday Mr. Justice Cozens-Hardy granted a compulsory order for winding up this company on the petition of Messrs. Glyn, Mills, Currie & Co.

Mr. YOUNGER, Q.C., on Wednesday mentioned the petition against the company and said before granting the order the learned judge had asked if anyone appeared for the company, and as no answer was given his lordship presumed the order must go. The petitioners had misunderstood the fact that negotiations for reconstruction of the company were still proceeding, and if carried through (as they probably would be) everyone would be paid. Counsel now asked that the order might be stayed, and that the petition might be put in the paper in a fortnight's time.

Mr. Justice COZENS-HARDY ordered the petition to be restored to the paper on July 10, and in the meantime to stay the order.

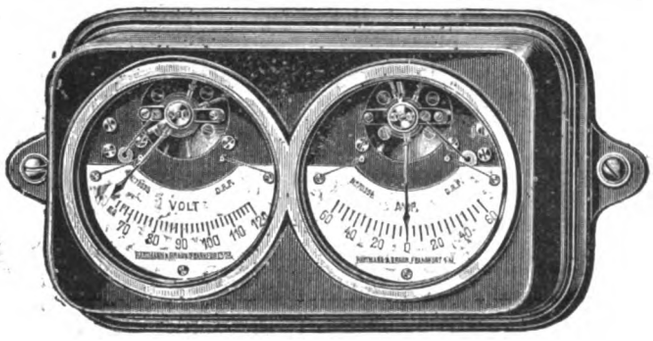
COMBINED VOLT AND AMPERE-METER FOR ELECTRIC TRAM AND MOTOR CAR WORK.

The combination volt and ampere-meter, shown one-third size in the accompanying illustration, is placed on the market by Messrs. O. Berend & Co., of Basinghall-avenue, London, E.C., and is especially designed for electric railway, tram or motor car work, for electric launch and crane work, and for use on small switchboards where space for separate instruments is frequently not available. Both instruments are constructed on the Deprez d'Arsonval principle—a moving coil in a permanent magnetic field—and are mounted in an air and watertight iron case. Iron has been selected for the case in preference to aluminium, as it renders the case less liable to accidental damage and at the same time protects the instruments from external magnetic fields. The slightly increased weight arising from the use of iron is therefore more than compensated for by the increased accuracy of the instruments and the efficient protection this material affords. Each instrument is entirely independent, and in the event of damage can be replaced without interfering with the other.

It is claimed that the frame on which the moving coil is wound, in fact, the complete coil, has been kept as light as possible, which is of great importance in instruments exposed to extreme vibration in use; moreover the powerful damping action of the magnetic field renders the instruments absolutely deadbeat. The dials of the instruments are protected by glass covers of $\frac{5}{16}$in. plate glass, bevelled and bedded into the case in cement. As will be seen, the pointers are not arranged opposite. With the pointers side by side, and pointing either upwards or downwards, errors in reading due to the instruments being at an angle to the observer's eye are practically eliminated.

The amperemeter scale is arranged either with zero in the centre or with zero somewhat away from the centre, as the rate of charging is scarcely ever at the maximum rate of discharging, and this design



admits of higher readings for the discharge. The scale can, of course, be graduated with zero at the left hand for motor work. The instrument shunts for current measurement are not fitted in the case, but can be fitted where most convenient, which saves taking large cables to the instrument, the connections from the instrument to the shunt being made with small flexible leads about 2¼ yards long; these flexibles should not be cut or lengthened, as this would affect the calibration of the instrument.

The voltmeter scale can be arranged either to read from zero or from any desired initial pressure. In the latter case the initial readings are about half the maximum limit, a more open scale at the normal working pressure can thus be obtained.

The voltmeter resistances up to 160 volts are mounted inside the case, but for higher pressures the resistances are in separate cases with perforated metal sides.

The above arrangements also apply to this type for switchboard work, and the instruments can be supplied with either back or front connections for this purpose.

City and Guilds of London Institute.—The report of the Council upon the work of this Institute for the year 1899 is just issued. This is the 20th year of the Institute's working, and a perusal of the report shows the important position occupied by the Institute in connection with secondary education. It is interesting to read that many students of the Institute are at present engaged in the military operations in South Africa, and the names of these students are given. Further, most if not all of the assistants in charge of the Marconi wireless telegraph apparatus in South Africa are men from the Finsbury and Central Colleges. A communication has been received by the Council from the Secretary of State for War offering 15 commissions in the army (viz., 10 in the Royal Artillery and five in the infantry), to students in the schools and colleges maintained by the City and Guilds of London Institute. Much matter of a similarly instructive character is given in the report, which can be obtained at the head offices, Gresham College, Basinghall-street, London, E.C.

TRAMWAY AND LIGHT RAILWAY ACCESSORIES AT ISLINGTON.

In another portion of this issue space is given to a description of the chief electrical features of the Tramways and Light Railways Exhibition now being held at the Agricultural Hall, Islington, London, and those particulars may here be supplemented by a cursory reference to the remaining exhibits, which give the exhibition a fairly representative character. The show is not a large one, but may be taken as an earnest of what is to follow. In the near future an electric tramway and light railway exhibition will doubtless have to be run on a much more extensive scale; for there is gradually being developed all the material for a most instructive and interesting display of electrical power and traction, calculated to vie with the most ambitious of the Earl's Court shows. From the commercial aspect such a show would undoubtedly be remunerative. The British public has by this time become fully acquainted with the overwhelming advantages of electrical over all other kinds of illumination, but it has still something to learn in respect to the advantages of the application of electricity to domestic purposes of almost every kind—to the propulsion of vehicles, and for driving machinery. In London especially, the public knows little of the great development of these branches of the electrical industry, and the time is near at hand when an opportunity on a large scale, with all the éclat of a royal inauguration &c., should be provided for its delectation. This expression of our views is not intended to detract from the usefulness or the interest of the Islington show, which, although small, serves a useful purpose in bringing together under one roof many of the latest improvements in electric tramway and light railway equipment. We miss from the show a great many of the leading firms in the electrical industry, who most probably at the present time are much too busy to give the necessary attention to such secondary aids to business as a small exhibition must necessarily be; but, notwithstanding, this the list of exhibitors include many firms in the first rank. We have only room here to deal briefly with the principal remaining exhibits.

Messrs. Askham Bros. & Wilson, of Sheffield, show an infinite variety of points, crossings, springs, tyres, plates, tools, and general accessories for permanent way construction, similar to those supplied by the firm to Nottingham, Manchester, Halifax, Blackburn, Aberdeen, Dundee, Glasgow, Bury, Dublin, Liverpool, London, Bristol, Sheffield, Bradford, Birmingham, Hull, Middlesbrough, Oldham, Birkenhead, and other towns, and to the numerous lines owned and worked by the British Electric Traction Co. Wherever electric tramway working has been introduced this firm's manufactures are much in evidence.

Messrs. R. Becker & Co. show several continuous-current electric motors of their enclosed type, one of which is at work driving a patent circular cold-sawing machine of the same firm's manufacture.

At stand 18, at the top of the hall, is a neat display of the well-known cables of the British Insulated Wire Co. Typical examples are shown of paper-insulated cables used on the Aberdeen, Glasgow, Manchester, Bradford, Blackpool and Fleetwood, Sheffield, and many other tramway lines in this country. A short length is also shown of the three-phase cable to be used on the Isle of Thanet tramways, now in course of construction and expected to be opened, in part at least, in the autumn. Some good examples of section pillars are also shown at this stand.

At the British Thomson-Houston Co.'s stand, No. 40, is shown a fully-equipped car, similar to those now being supplied by the company to the London United Tramways. A fine type of car, built by Messrs. Hurst, Nelson & Co., mounted on Brill trucks, is also shown here. In this car electric heaters are installed, controlled by a simple switch, giving several easily-regulated gradations of temperature. A quantity of B.T.H. standard overhead material is a feature of the exhibit.

The Brush Company show a bogey vestibule car arranged to seat 44 passengers in two compartments, divided into two classes if desired, or into smoking and non-smoking. The car has a middle entrance, and is a fine example of what can be turned out at Loughborough. A number of tramway controllers are also shown.

The Cape Asbestos Co., at stand No. 72, show a model of a steam boiler covered with the company's patent blue asbestos removable mattresses, and also several steam and hot water pipes, flanges, &c., covered with removable blue asbestos pipe covering. Some interesting examples of crude blue asbestos are also displayed, from the company's mines in Cape Colony. This company are issuing a timely pamphlet containing "Notes on Locomotive and other Boiler and Steam Pipe Coverings." Blue asbestos is claimed to be considerably lighter and to yield a longer and stronger fibre than other classes of asbestos. For use in the form of mattresses and ropes it makes a removable covering for boilers and steam pipes the superiority of which over cement coverings is generally admitted. Removable coverings are made in blue asbestos which are shown by Government experiments to give excellent results compared with many other forms of boiler covering, including silicate cotton, hemp,

Digitized by Google

rope, hair, felt, and Pascal cement. A removable covering for steam pipes is of course of equal if not of even greater importance than for boilers, and for this purpose a blue asbestos hollow rope is woven and is coiled round the pipe. This can be removed and replaced over and over again, and allows of perfect freedom of expansion and contraction in cases where cement covering is likely to crack and fall off. These blue asbestos ropes are made in four sizes. The fact that the company's commodities are in extensive use in the chief electricity supply stations, in many of the largest factories, as well as in the British, Japanese, and other navies and on the locomotives of British, Continental, and Colonial railways is fairly claimed by the company as a standing testimonial to the claims made for Cape blue asbestos goods.

At Messrs. CHAS. CHURCHILL & Co.'s stand, No. 64, a grand exhibit of high-class American machine tools for an infinite variety of work are on view. This exhibit deserves careful attention from machine tool users.

An interesting exhibit is that of the CONSOLIDATED CAR-HEATING CO., who show a variety of electric car-heaters, for which many advantages are claimed.

Messrs. CROSSLEY BROS.' exhibit of gas and oil engines is a representative one. The "O. E." type of high-speed gas engine is shown driving a dynamo for electric lighting. The engine gives 12 actual H.P. as a standing working load.

The combined exhibit of Messrs. DICK, KERR & Co., the ENGLISH ELECTRIC MANUFACTURING Co. and the ELECTRIC RAILWAY AND TRAMWAY CARRIAGE WORKS, will be found at stands Nos. 25, 26 and 27. Here are on show four examples of tramcars—No. 1 a vestibule top-seat car for heavy town service, No. 2 a cross-bench car for high-speed summer suburban traffic, No. 3 a 4-wheeled top-seat car, and No. 4 a 4-wheeled single-deck car, with seating capacity for 26 passengers. The car bodies in each case have been manufactured by the Electric Railway and Tramway Carriage Works, and the electrical equipment by the English Electric Manufacturing Co. A large exhibit of permanent way plant and material, including rails, foundations, junction points, rail joints, &c., manufactured by Messrs. Dick, Kerr & Co., is also displayed.

THE ELECTRIC CONSTRUCTION Co. make a fine show of E.C.C. plant, including a 70 kw. variable ratio transformer now largely employed in the distribution of current on the Oxford system for lighting. These machines are also employed on the City and South London Railway as reducers. The arrangement of double field in these transformers, enabling the ratio of the primary and secondary voltage to be varied within any desired limit, is patented. Other exhibits at this stand include a 30 H.P. tramcar motor, stationary motors of the "Bushbury" type, the E.C.C. form of trolley for side suspension, switchboard apparatus, &c.

The ELECTRIC TRAMWAY EQUIPMENT Co. show a number of trolley line and other insulators, made on the "Verus" insulation. Other features of this exhibit are a good show of cars, arm suspensions, frogs, switches and crossings.

At MESSRS. ELLIOTT BROS' stand, No. 26, at the lower end of the east side of the main hall, is displayed a fine group of electric measuring instruments, speed indicators, recording watt and ammeters, and an instructive switchboard panel showing a variety of instruments and methods of fixing to the switchboard for easy reading. A Board of Trade panel shows the instruments necessary for carrying out the tests required by the Electrical Standardising Department in connection with electric tramway undertakings. This is the best instrument exhibit in the hall.

Messrs. S. Z. DE FERRANTI (Ltd.) are content with an excellent display of photographs of Ferranti plant and apparatus for all classes of lighting and power work, which has been installed in many of the chief supply stations of the country.

MESSRS. WALTER T. GLOVER & Co. have a large exhibit in the centre transept, and here samples of a large variety of this firm's well-known types of cables for lighting, power and traction work, are on show, including a drum of single lead-covered cable for tramway feeders. A notable feature in this exhibit is a good display of joint boxes, straight tee and four-way jointers for single concentric, double concentric, twin and three-core cables of all sizes, including a patent cable connector.

THE BRITISH MANNESMAN TUBE Co. have on show a large variety of traction poles, arc lamp posts, trolley poles, &c., in great variety of design and ornamentation. Large quantities of these poles have been supplied for the principal public installations in Great Britain and the Continent.

Amongst the indispensable accessories for tramway working, car-wheels form an essential part. An excellent exhibit of these wheels is made by Messrs. MILLER & Co. at stand No. 24. It is claimed for this firm's manufactures that they have run under electric motor cars in direct competition with the best wheels of other makes, and have given very satisfactory results. A special design of wheel press is shown, working up to a total pressure of 150 tons. A working model is exhibited at this stand of a system of chilled iron double shifting points, as supplied to the Naples Electric Tramways.

Among other well-known firms exhibiting a variety of apparatus and accessories for electric tramway working may be mentioned Messrs. W. F. Dennis & Co., Doulton & Co., Simplex Steel Conduit Co., St. Helen's Cable Co., Estler Bros., Le Carbone, Ohio Brass Co., Mossberg Roller Bearings, Wheeler Condensing & Engineering Co, and the Worthington Pumping Engine Co.

It is fitting that in an exhibition dealing with the latest specialities in tramway and light railway building and equipment, special attention should be given to minor but essential details, and the exhibition under notice is particularly strong in some of these accessories. A noticeable feature is the large number of patent collapsible seats, the object of all the inventions alike being to provide a dry seat for the passenger. Little exception can be taken to the seat which secured the first award. This is a weighted seat for each passenger and tilts to an angle on the passenger rising, leaves the under part of the seat free for advertisements (not an unimportant feature from the tramway owners' point of view), is reversible by the shifting over of the upper rail, and unless the rain is accompanied by a strong wind will keep the seat quite dry. Many ingenious devices (some very simple others much too complicated) are shown in the annexe adjoining the large hall, where also may be seen several examples of tramcar protection fenders of American design and manufacture.

MUNICIPAL, FOREIGN & GENERAL NOTES.

Correspondence for "The Electrician."—Correspondence, both editorial and business, for *The Electrician*, is suffering such considerable delay at the hands of the postal authorities that communications requiring urgent attention should be sent by rail or special messenger when possible. Any communication containing drawings, original MS., or remittances should be separately advised.

Acts of Parliament.—The Royal Assent was given on June 25 to the Electric Lighting Orders Confirmation Acts (1900), Nos. 1, 3, 4, and 5, and the Central London Railway Act (1900).

Ambleside.—The Local Government Board decline to sanction the agreement between the Council and the Windermere Electricity Supply Co. for the supply of electric energy to Ambleside on the ground that the latter have no powers to supply electricity out of their district, and the Council would either have to erect their own generating station or lease their order to the Windermere Company. The Council deem it inadvisable to incur further capital expenditure at present, and the company is to be approached with a view to taking a lease of the order.

Ashton-under-Lyne.—In presenting his annual financial statement to the Council on Wednesday, Ald. Wilson, chairman of the Finance committee, stated that there was a deficiency on the working of the electricity department for the past year of £1,060. 11s. 8d. The account would, however, soon rectify itself and show a surplus instead of a deficiency. The electricity department was still an undeveloped department of the Corporation, but it was progressing and advancing towards prosperity.

Ballarat (Victoria).—The British Insulated Wire Co. have completed the purchase of the undertaking of the Ballarat Horse Tramway Co. for £12,000. It is proposed to reconstruct the lines for electric traction, and to considerably extend the system, the Council being asked to grant a lease for 30 years.

Batavia (Java).—The electric tramway (serving the Sourabaya and Madura districts), which was commenced in 1898, is now completed and in working order for one-third of its length.

Battersea.—The ceremony of laying the foundation stone of the electricity supply station will be performed on July 28, by the chairman of the Vestry (Mr. W. Matthews).

The dispute with the Post Office authorities on the subject of laying telegraph tubes has been settled. The Highways committee reported that it had been decided to give consent to the works on the following conditions:—

(1) The Postmaster-General shall make good damage done in the execution or maintenance of the work. (2) The Postmaster-General shall give notice in writing to the Vestry, in case at any time any of the said telegraphs shall be used or required to be used to connect exchanges of the National Telephone Co. or exchanges of the National Telephone Co. and Post Offices. (3) On receipt of such notice as last aforesaid, the Vestry shall be at liberty, by notice in writing, to withdraw the consent hereby given so far as relates to any telegraphs to be used as aforesaid, and the Postmaster-General, if he objects to such withdrawal, shall take immediate steps to obtain a determination of the difference thus arising in manner prescribed by the Telegraph Act, 1878.

Birmingham.—The Corporation have acquired the site of the old general hospital in Summer-lane for £23,000. It will be utilised as an electric power station, from which energy for lighting, for tramways and for power will be supplied. The area purchased consists of about 4 acres.

Bolsover.—The Council have entered into an arrangement with the Sheepbridge Company for the electric lighting of Whaley Thorne.

Digitized by Google

Bournemouth.—Electric lighting is to replace gas in the upper and lower gardens, which form so important a feature of this town.

Brighouse.—The new sewage works at Cooper Bridge were formally opened by the mayor (Mr. Councillor Clay) on Saturday. The tanks and exterior of the buildings are lighted by enclosed "Ark" lamps supplied by Messrs. Johnson & Phillips, and a battery of chloride cells has been provided for the incandescent lighting of the works, manager's house, and committee rooms when the generating plant is not running. "Churton" dynamo, switchboard, and controlling apparatus is installed.

Cambridge.—Negotiations between the Council, the Cambridge Street Tramways Co., and the British Electric Traction Co. for regarding the acquisition of the local tramways have, we understand, been dropped for the present.

"Cassier's Magazine."—The July issue contains articles on "Electric Power for Factories," "Invention as a Factor of American National Wealth," "Machine Tools in the Mechanic Arts," "Economies in Machine-Shop Work," and "The Development of Flywheels."

Chatham.—The Chatham, Rochester & District Electric Light Co. will introduce the maximum demand system of charging for electric current from Oct. 1. The charge will be 7d. per unit for the first hour and 2d. after. The company will introduce "free" wiring. A consumer can, under this system, have the first six lamps fixed without initial charge. The revised charge for current to consumers will be 7d. per unit for the first hour and 2½d. after.

City of London.—The City of London Electric Lighting Co. has been granted permission to substitute 14in. by 11in. troughing for the 9in. by 6in. troughing at present in the Queen Victoria-street subway between Blackfriars and St. Andrew's-hill. Increased rent in accordance with the scale laid down by the Council in respect of the space which will be occupied in the subway by the larger troughing has to be paid.

Cleckheaton.—The Council have purchased land for the erection of electricity supply and refuse destructor works.

Cork.—Eighty-five additional public arc lamps are to be erected here. The annual charge for the supply of current to and for the maintenance of the lamps will be about £1,275, and the present cost of gas lighting (about 270 lamps will be displaced) is £766. 8s. 4d. The illuminating power of the arc lamps will be equivalent to 168,000 c.p., against 2,705 c.p. of the existing gas lamps.

Devonport.—An inquiry was held on Wednesday into the application of the Corporation to borrow £69,727 for electricity supply. The town clerk (Mr. A. B. Pilling) gave evidence of the town's assessable value, &c., and technical details were furnished by the borough electrical engineer (Mr. Charles Furness), who explained that the station premises on the waterside frontage would be capable of storing about 1,200 tons of coal. It was proposed to have three steam dynamos, one of 300 H.P. (which would be used for lighting), one of 600 H.P. for traction work, and a third unit of 600 H.P. would be held in reserve. They would start the working of the plant with an assured demand for 700,000 units per annum. The system of distribution would be the low-pressure continuous current.

Driffield.—The Council has resolved to oppose an application by the Northern Counties Electricity Supply Co. for a provisional electric lighting order.

Dundee.—The Perth-road electric tramway route is approaching completion, and the line will be ready for traffic about the middle of July.

Electrical Bills.—In the Westminster (London) County Court on Monday, Judge Lumley Smith, Q.C., heard a claim (Smeeton and Page v. Collings) for £2. 5s. 9d., balance of a bill for £32. 1s. 9d. for electrical work done. An estimate was made for a small electric job at defendant's house to include all materials, casings, tubing, cables, wires, switches and wall plugs, and wiring, for 16 additional lamps. The estimate was £13. 10s. Other items in the rendered account for the work were said to be for extras ordered afterwards. The JUDGE: If I have a pair of trousers made I should not expect a bill to come in for extras. Mr. FIRTH (for plaintiff): Electrical bills are always made out like this. The JUDGE: I have paid a good many, and it was not so. The judge said the charge was in excess of what it ought to be, and found for plaintiffs for 30s. and costs.

Electrical Cabs in London.—On the subject of the failure of the London Electrical Cab Co., Mr. Carl Oppermann (who has occupied for many years a prominent position in the electric automobile industry) writes:—

TO THE EDITOR OF THE ELECTRICIAN.

Sir,—One would think, from reading the circular of the directors of the late London Electrical Cab Co. (Ltd.) that the electrical vehicle was an impossibility, and that the vast sum subscribed by the public was used in endeavouring to put a practical vehicle on the streets. From the manner in which the capital was spent, some might feel inclined to suggest that the only reason for which the company was started was to obtain the £25,000 for the valuable (*sic*) licences, without which, we were told, you could not make electrical vehicles at all, although the electrical landau shown to would-be shareholders at Winchester House, E.C., was made under quite a different system, and one for which no licence was required other than that conveyed to the purchaser of any patented article.

The directors say that although the designs were approved of by engineers and experts, several defects developed themselves in the vehicles. To my knowledge, the directors were advised to make only two cabs in order to find out what was required to stand the London street traffic; but instead without any actual experience to guide them, the directors put in hand 40 cabs at once. They say these were too heavy for the rubber tyres. Of course 38cwt. to 40cwt. was too much for the same kind of wheels and rubbers that one would find on an ordinary four-wheel horse-drawn cab weighing only 8cwt., and which were put on the first electric cabs. The vibration, too, we are told, destroyed the cells. One cannot be surprised at vibration in a vehicle built practically without springs. What further damaged the cells was the enormous amount of the current taken from them owing to the want of attention to the gearing and sending out of the cabs without proper oiling arrangements. Not any of the vehicles had an ampere meter, so that however anxious a driver might be to run the cabs successfully, he had no certain means of telling whether his cab was running properly or not.

Then there was the driver bogey. Can one expect men who have a living to earn not eventually becoming disheartened and reverting to the old horse-drawn vehicle in consequence of the continuous breakdowns—breakdowns which could in all cases have been prevented by proper supervision and examination of the cabs after each day's run? I know that it is possible to obtain any number of men who could, with slight training, properly drive an electrical vehicle.

Consider, again, the large sum spent upon the alternating transformer plant put down to supply current for the accumulators, and which turned out to be practically useless, and was abandoned, as the current ultimately cost 4d. or so a unit, a continuous-current plant being afterwards put down at a further cost of several thousand pounds, although all the current necessary for the undertaking could have been obtained without a farthing outlay at about 1½d. per unit from supply stations in London.

To show that electrical vehicles can be made to run, and at a profit, when properly managed, you have only to turn to New York, where, starting with a modest 20 cabs, the number is now increased to over 200; or to Berlin, where electrical omnibuses are in use successfully; and also to some electrical victorias, which have been recently hired out in London and have proved an unqualified success. But no company started to hire out electrical carriages can ever prove profitable if run upon the lines of the late London Electrical Cab Co.

That smart, comfortable, and reliable electrical carriages will eventually appear in our streets in large numbers there is not the shadow of a doubt, as their popularity is beyond all question. The entire absence of noise and vibration, heat, or unpleasant odours either to the passengers or to anyone in their immediate neighbourhood, and the ease with which they are controlled, all tend to make them an ideal means of locomotion.

Glasgow.—The revenue of the Corporation tramways for the year ended May 31 amounted to £469,965, compared with £439,224. 1s. 8d. in 1899, and the working expenses to £344,661, against £318,105. 18s. 11d, leaving a balance of £125,304, compared with £121,118. The balance has been applied as follows: Rent of Govan and Ibrox tramways, £1,983; interest on capital, £17,295; sinking fund, £11,636; depreciation, £32,079; common good, £12,500; general reserve, £46,809. The traffic revenue showed an increase of £31,658. The revenue on the electric system was about 1s. 2d. per car mile, and from the horse cars 11½d. During the year about £400,000 has been spent on renewal of track and on conversion and electrical equipment.

Hackney (London).—To encourage the demand for electric current the Electric Lighting committee, on a report from the consulting engineer (Mr. Robert Hammond), recommend that the charge for current for private lighting be fixed at 4d. per unit, and 2d. for motive power.

Hammersmith (London).—The Vestry have fully discussed the question of extension of the electric lighting mains, and have decided that 24 additional thoroughfares should be scheduled, and the work carried out at an estimated cost of £8,877. In order to meet the cost of these extensions, the necessary transformers, &c., the Vestry intend to borrow £15,500. The Electric Lighting committee have reported against the proposal to reduce the charge for electric current.

Hanley.—The special Electric Lighting sub-committee recently appointed to consider and report upon the reasons for the deficiency shown on the working of the electricity department for 1899 presented the result of their investigations to the Council on Tuesday. The borough engineer (Mr. Joseph Lobley), in conjunction with the electrical engineer (Mr. C. A. Cowell), had prepared reports on the matter. Mr. Lobley stated that loans amounting to £70,009 had been sanctioned, and £64,990 had been borrowed. Applications had been made for further borrowing powers for £4,000 to cover cost of boiler-house requirements. During the past year £7,044 had been expended on capital account, bringing the total expenditure up to £67,829. The capital outlay amounted to £55 per kw. of generating capacity. There were only three local authorities and one company where the expenditure had been lower than Hanley. There was, therefore, no cause for apprehension as to the future financial success of the undertaking. The total capacity of the station is 1,224 kw. The maximum demand last year was 550 kw.; this year it might be expected to reach 650 kw. There was no ground for the suggestion

Digitized by Google

that the plant was obsolete and out of date, and should consequently be valued at much less than cost price. The land had not become less valuable, and the buildings were maintained up to the original value, or even beyond it. As regarded the mains, there was no general experience extant as to how long they would last. No sign whatever of depreciation had become apparent, and all local defects arising from extraneous causes were put right out of revenue. The street lamp posts did not deteriorate, and the arc lamps were maintained out of revenue. The same remark applied to all other items, with the exception of machinery, which must be specially treated. The early Brush engines and rope-driven dynamos were not quite up to date. The capacity of these Brush engines and dynamos was 324 kw. The remaining plant, including boilers, condensers, pumps, Ferranti steam alternators, rectifiers, &c., were thoroughly up to date. The machinery, including that which was not quite up to date, was doing exceedingly useful work. The mechanical stokers had not proved altogether a success, notwithstanding the efforts of the committee to secure good ones. New furnaces had been provided out of revenue, and thus the plant was maintained at its original value. Mr. Lobley further states that there is no dual control. He did not in any way interfere with Mr. Cowell in the control of his staff. The expenditure on revenue account amounted to £7,632, the receipts to £8,609, leaving a gross profit of £1,177 and interest and sinking fund charges amounted to £3,446, causing a deficiency of £2,269, which had had to be transferred from the general district rate account. Places of worship were charged 4d., and heating and power 2½d. and 1d. per unit, but the total revenue from these sources had been less than £100 a-year. Notwithstanding the reduction in the price charged, the total revenue had steadily increased year by year. The expenditure had also increased, and particularly during 1899. The deficiencies began with the reduction in the charge per unit. It was quite expected that there would be some deficiency for the first year or two. If the original charge of 6d. and 3d. per unit had been adhered to, the revenue would have been greater in 1895 by £200; 1896, by £300; 1897, by £800; 1898, by £900; and 1899, by £1,400; or a total of £3,600. The increase of the sinking fund continued, and now amounted to £5,638. Their high figures charged on revenue account for maintenance disposed of the argument that this fund should not be regarded as a valuable asset to its fullest extent. The expenditure on revenue showed a great increase in several items. If the works had been carried on during 1899 at the same price per unit as in 1898 (2·48d. instead of 3·18d.), the gross profit would have been £2,746 instead of £1,177. There was an increase in the cost of coal of £959, after allowing for the additional output. The average price received for private supply in Hanley was 4·09d. per unit. Sixteen local authorities and three companies in this country had received a lower average price. To a considerable extent Mr. Cowell's report covered the same ground as Mr. Lobley, but went more into detail as to works costs, maintenance, renewals, &c. It concludes by stating that a considerable sum could be saved per year if better arrangements were made for handling coal. In the plans prepared for the new boilers, &c., this had been provided. Hanley was one of the very few stations that did not work with fuel economisers for heating the feed water. What would do more than anything to reduce the quantity of fuel used would be to put down economisers in connection with the present boilers as well as with the proposed new ones. In the plans now being sent to the Local Government Board this provision was included. The sub-committee reported that, after full consideration, they were of opinion that the deficiency in the revenue account for last year was to be attributed to the following causes: (1) Too early reduction in the price of current before a reserve fund had been formed; (2) increased cost of fuel, wages and materials; (3) abnormal repairs to generating plant; (4) increased charges to sinking fund and interest on further capital. They decided to recommend the Council to increase the present prices for the supply of electric current of 5d. and 2½d. to 6d. and 3d. per unit from July 1, less discounts, as before. They also recommended that the charge for supply to places of worship be increased from 4d. to 4½d. per unit, and for heating and power supplied through separate meters from 2½d. to 3d. up to four hours' consumption per day, and 1d. per unit after. The adoption of the minutes was carried after considerable discussion.

Holborn (London).—On the recommendation of the Works committee it has been decided to invite the electric lighting companies serving the district (County of London & Brush Co, the Metropolitan Electric Supply Co. and the Charing Cross and Strand Electricity Supply Corporation) to send in estimates for lighting the district electrically.

Infirmary Lighting.—On the recommendation of the Building committee the Southampton Board of Guardians are providing an electric lighting installation to their new infirmary.

Kilmarnock.—The council have acquired a site for electricity works at Riccarton.

Lancaster.—Profit on the Electric Lighting department for the past year was £420. 18s.

Light Railways.—The Peterborough and District Light Railways Order has been submitted to the Board of Trade for confirmation. Objections must be lodged by July 21.

An inquiry was held on Friday into the application of the Oldham, Ashton & Hyde Electric Tramway (Ltd.) for an order to authorise the construction of a light (electric) railway from Ashton, through Dukinfield to Hyde, and from Hyde to Denton. The Ashton, Dukinfield, Hyde, and Stourbridge Corporations and the Denton Council opposed, and the chairman (Earl Jersey) announced that the Commissioners could not, in face of the strenuous opposition of the local authorities, force a scheme of the kind upon the district. The application was accordingly refused.

The Bexhill and St. Leonards light railway order was recently confirmed by the Board of Trade. The promoter (Mr. W. M. Murphy, J.P.) is also promoting a bill for the construction of electric tramways in Hastings, and both schemes will eventually be connected up and probably amalgamated.

At a special meeting of the Northwich Council the engineers of the United Kingdom Tramway & Light Railway Electric Syndicate (Major Tulloch and Mr. H. W. Handcock) explained the proposal to construct a light electric railway on the overhead trolley system between Northwich, Winsford and Middlewich. For the Northwich district it is proposed to commence the line on the Manchester main road, run to the station, carry a branch to Broken Cross, construct the overhead system from the station through the town and on to the Winsford and Middlewich main roads. These towns would thus for the first time be connected. Goods, as well as passengers, will be carried. The Council unanimously adopted a resolution in favour of the scheme, but subject to details to be submitted to a future meeting being acceptable.

An inquiry was held on Wednesday, at Mansfield, into the application of Messrs. Fell, Lewis & Kershaw for authority to extend their original electric tramway scheme for Mansfield and district. Three new lines were proposed. After hearing evidence, the chairman (the Earl of Jersey) announced that the Commissioners would report in favour of granting the order.

London County Council.—At Tuesday's meeting it was decided that, having regard to the price at which the recent issue of County Council stock was subscribed, the rate of interest for loans granted by the Council to the London local authorities should remain at 3½ per cent. Loans of £20,000 to Battersea, £10,000 to Poplar, and £20,000 to Shoreditch for electric lighting purposes were approved. The Asylums committee presented a report involving a capital expenditure of £39,000 for a central station at the Horton estate for the supply of water and electricity to the Asylum and to the suggested epileptic colony. The report states that the buildings have been so designed that they could be extended from time to time to whatever capacity may be required. The lighting plant is for an installation of 3,800 lamps, equivalent to 8,187·8 c.p. lamps, and will also provide current for 16 motors ranging from 1 B.H.P. to 22 B.H.P. The three-wire system at 400 volts is recommended, with 200 volt distribution in all rooms occupied by patients and staff. The estimated cost of the electric lighting plant was £18,000. Consideration of the report was postponed for a week.

Lowestoft.—The Council have applied for sanction to borrow £20,000 for electric lighting extensions. This sum is to be applied as follows: For extensions already authorised £4,760, additional mains £1,900, feeders and pilot wires to Pakefield and Park £3,890, additional distributing cables to be laid when desirable, together with additional meters, cut-outs and house service connections, £5,000; additional steam dynamo, boiler, steam pipes, switch gear, &c., £3,000; legal and advertising expenses, printing, engineering fees, &c., £1,450. The Council have also decided to invite offers from firms willing to undertake the wiring of premises on the hire-purchase system. The following charges have been fixed for the supply of electric current for lighting: 7d. per unit for the first 100 hours' maximum demand per quarter, and 3d. per unit beyond. For power 7d. per unit for the first hour's maximum demand per day and 1½d. after. The Council have further decided to appoint a resident electrical engineer at a salary of £200 per annum. The consulting engineer (Mr. W. C. C. Hawtayne) has been instructed to submit a specification for the lighting of the town hall.

Lymington.—Some time ago the Council entered into a contract with the Lymington Electric Light & Power Co. for public lighting for five years. The contract for gas lighting terminated on 24th inst., and the gas company refused to continue the lighting for a shorter term than 12 months. The Electric Light Company intimate that they will not be in a position to supply current for three months, but offer to pay the cost of gas lighting in the meantime.

Manchester.—At the Council meeting on Wednesday it was resolved, on the motion of Mr. F. Brocklehurst, to refer a memorial from the Mutual Telephone Co. in regard to their application for a municipal telephone licence to a special telephone committee.

Melbourne.—For some time past negotiations have been proceeding between the Electric Lighting & Traction Co. of Australia and the Victorian Postal Department, regarding the proposed

Digitized by Google

transfer of the undertakings of the A. U. Alcock Electric Light & Motive Power Co. and the New Australian Electric Co.; but it has now been discovered that the Electric Light and Power Act does not authorise the Governor in Council to grant the transfer sought. An alternative arrangement has, however, been come to. The new English company will seek an Order in Council empowering them to carry on operations for the unexpired term of the existing orders held by the A. U. Alcock and New Australian Companies, which will be cancelled, and at the same time the Postmaster-General will introduce a bill in Parliament to amend the present Act, so that the Governor in Council may be able to grant transfers. Some three months will have to elapse before the orders can be issued. The British Insulated Wire Co., who desire to secure similar powers in regard to Ballarat and Geelong, has also determined to apply for an Order in Council.

Motor-Driven Passenger Boats.—The police authorities of Stettin and Swinemünde (Germany) have issued instructions requiring owners and masters of vessels driven by electric power, carrying passengers to and from either of these ports, to provide themselves with certificates from the local authorities granting permission to carry passengers.

Municipal Telephony.—It is stated that the response to a canvass made by the Grantham Council as to the amount of support the ratepayers were prepared to give the proposal to establish a municipal telephone exchange, has not fulfilled the expectations of those members of the Council who have taken the matter up with some spirit.

Newport (Fifeshire).—The Newport Gas Light Co. desired to obtain electric lighting powers but the Burgh Commissioners notify that they propose not only to themselves apply for a provisional order but also to purchase the gas works. The company's proposal has therefore been dropped.

Oldbury.—The District Council has come to an understanding with the British Electric Traction Co. as to the electrical equipment and leasing of the local tramways. The lease is to be extended by 21 years and the lines worked by the company. It was announced at the Council meeting last week that the Oldbury to Dudley electric tramway would shortly be opened for traffic.

Pemberton.—An inquiry has been held into the application of the Council to borrow £20,000 for electric lighting. Mr. Leach opposed on behalf of a section of the ratepayers, and said that at the present time the bulk of the residents did not even use gas, whereupon the chairman of the Council said that that was one of the reasons the Council thought it better to put down an electric lighting installation. In addition to other objectionable features accidents from paraffin lamps had been frequent.

Portsmouth.—The Tramways committee have decided to increase the original estimate of £24,000 to £32,000 for electric tramways; 80 cars are to be placed on the lines instead of 60.

Redfern (N.S.W.).—When Major Cardew recently visited Australia for the purpose of reporting on the electric lighting question for the Sydney Municipal Council, he was also invited to consider the advisability of extending and improving the electricity works at Redfern. The report which Major Cardew presented to the Council concludes as follows:—

My advice to you is to make the best of what you have got, and when the Sydney electric lighting scheme has come into operation make the best bargain you can with the City Council for supplying current for your street lighting and for the goodwill of your undertaking. If you should, however, decide to continue the electric supply business, you should certainly remodel the whole of your arrangements and lay some underground mains. The total cost of conversion would be about £10,000.

A special meeting of the Council was recently held for considering this report as well as that of the Electric Lighting committee, when it was decided to adopt the reports in so far as they recommended that the management of the electric light works shall be placed under one head at the power-house. It was also decided that the future tariff of wages to be paid at the generating station should not exceed that suggested by Major Cardew, viz., electrical engineer, £3. 15s.; engine driver, £3. 5s.; one fireman and driver combined, £2. 10s.; one assistant fireman, £2; one wireman, £1. 15s.; one lamp cleaner, 15s. Total £14.

Rugby.—The Council obtained a provisional order in 1898, and about 12 months ago issued circulars to ratepayers to ascertain their views on the advisability of establishing electricity works. A committee has been appointed to obtain offers from companies desirous of establishing electricity works.

St. Ann's-on-Sea.—The second site for the electricity supply station, which involved a second Local Government Board inquiry, has been abandoned and a third site chosen.

St. George's, Hanover-square (London).—Some time ago the Westminster Electric Supply Corporation offered to supply current to and maintain 600 lamps in this district at a cost of £13,500 per year, or 756, which the Lighting committee considered necessary, for £16,932 per year, without any capital expenditure on the part of the Vestry, and the total cost was to be subject to annual reduction. The corporation's right would extend over 32 years, but if the period of supply was limited to 10 years, the annual cost would be £15,000 for 680 lamps, and £19,230 for 756 lamps. Gas now costs £10,000 a year, so that a penny rate would cover the additional cost of the electric light. At the meeting of the Vestry last month the consideration of this offer was deferred for six months. The large increase in the charge for gas has led to the matter coming up for earlier consideration, and at the meeting last week it was decided (by 40 to 22) to rescind the previous resolution. The gentleman on whose initiation it was again discussed (Mr. W. Everitt), said there was no parish in London which was worse lighted than St. George's. Electric lighting was the best, and seeing that the Vestry could not themselves undertake a scheme he thought they ought to accept the offer of the Westminster Electric Supply Corporation. Col. Sir Howard Vincent, M.P., and Mr. Antrobus also supported the resolution to extend the electric light. Eventually a resolution sanctioning the extension of public electric lighting throughout the parish, and authorising the Electric Lighting committee to obtain expert opinion upon the offer submitted by the Westminster Corporation was approved.

Swansea.—The Corporation have decided to extend the electric lighting area to Morriston, Port Tennant, Cwmbwrla, Sketty Road, and Brynmill.

Tamworth.—Messrs. Handley & Shanks have notified the Council of their intention to proceed with the application for a provisional electric lighting order. The Council have resolved to oppose.

Tewkesbury.—The Council last week deferred the discussion of a motion to apply for a provisional order.

Thornhill.—The increase in the price of gas has led to an agitation in favour of the introduction of the electric light. The advent of an electric lighting company would be welcomed.

Torquay.—An inquiry was held on Tuesday into the application of the Council to borrow £15,000 for electric lighting extensions. The town clerk explained that the electric lighting undertaking had developed so rapidly that additions to the plant, which was laid down so recently as 1899, was imperative. At the end of March, 1898, there were 55 consumers, but on March 31 last the number was 221. The total equivalent number of 8 c.p. lamps connected in March, 1898, was 5,688, of which 3,310 were private lamps, and in March last there were 10,070 lamps. Some applications in hand could not be dealt with. The total revenue for the first year was £2,837, last year it was £3,699. There was a gross profit of £1,057 on the first year's working and of £1,256 on the second year's. Interest and sinking fund in each year was £1,188. There was thus a deficit of £138 on the first year, and a profit of £67 on the second. It showed the undertaking was rapidly coming into favour and was paying its way. Technical details were given by the borough electrical engineer, Mr. P. Storey.

Train Lighting.—The managing committee of the South Eastern and Chatham Railway Co., who are making large additions to their rolling stock, have made experiments in lighting their trains, and, having regard to the risk attendant upon the use of gas, have decided that the whole of the passenger trains on the combined system shall be lighted electrically.

Water-Power Utilisation in Italy.—A company, entitled La Società Italiana per le Forze Idrauliche del Veneto, has been formed in Venice, with a capital of £240,000, to put down plant to utilise available water power in the province of Venice. The company has acquired the rights to utilise the water power of the River Piavè (estimated at 40,000 H.P.) and of the Cellina torrent (22,000 H.P.) A 6,000 H.P. plant is to be at once installed, the electrical energy to be transmitted to Venice.

Watford.—The Council have decided to put down additional plant, and to apply for sanction to borrow £5,000 to cover cost of same.

Worcester.—An inquiry was held here on Tuesday into the application of the Council for sanction to borrow £1,000 for wiring premises in the district on the hire-purchase system. The town clerk explained that the proposed arrangement with the National Electric Wiring Co. had terminated. It was proposed to make such charge to consumers as would repay the capital outlay and interest in 10 years, the period of the desired loan. As most of the houses were let on yearly tenancies neither tenants nor landlords cared to undertake the installation, so the Corporation had drawn up a form of agreement to which the landlord would be made a party. The chief engineer (Mr. Hoadley) mentioned that he had worked out the average cost of electric current to all consumers. The cost to public houses worked out at about 3·3d. per unit, to shopkeepers and private houses about 4½d., and to churches and similar buildings, which required current for only a short period, to about 6d.

Worms (Germany).—Electricity supply works, estimated to cost about £55,000, are to be erected in this town by the Elektricitäts Aktiengesellschaft vorm. Schuckert & Co.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

TENDERS INVITED.

Extension of Time—Tunbridge Wells Corporation invite tenders for telephone instruments, apparatus, material, and accessories, particulars of which are set out in an advertisement. Copies of the specification can be obtained from the telephone engineer (Mr. A. R. Bennett), Castle Chambers, West Regent-street, Glasgow, and tenders have to be delivered to the offices of Mr. W. C. Cripps, town clerk, Town Hall, Tunbridge Wells, not later than Thursday, July 12.

Partick Commissioners invite tenders for the supply and laying of insulated electric mains, conduits, junction boxes, &c., and for the supply and erection of cast-iron arc and incandescent lamp standards, arc lamps, automatic switches, and other fittings. Specification may be obtained at the offices of the town clerk (Mr. Jas. Donaldson), 97, West Regent-street, Glasgow. Specification may be inspected (but not obtained) at the office of the consulting engineers (Messrs. Kincaid, Waller & Manville), 29, Great George-street, Westminster, S.W. Further particulars are set out in an advertisement, and tenders must be sent in to Mr. Donaldson by July 10.

Hammersmith (London) Electricity and Lighting committee invite tenders for insulated high and low-tension cables, junction boxes, &c., and cast-iron pipes, draw-box covers, &c, required, as per schedule, for 12 months. An advertisement contains further particulars, and specification, &c., can be obtained from the engineer and manager (Mr. G. G. Bell), 57, Fulham Palace-road, W. Tenders to chairman of committee by July 12.

Lowestoft Corporation require tenders for (1) direct-current meters, and (2) cutouts. Specifications, &c., can be had from Mr. R. Beattie Nicholson, town clerk, and can be seen at, but not obtained from, the office of Mr. W. C. C. Hawtayne, 9, Queen Street-place, London, E.C. Tenders to Mr. Nicholson, town clerk's office, Lowestoft, by 12 noon of July 3. An advertisement contains further particulars.

Beckenham District Council invite tenders for the "free" wiring of premises. Specification may be obtained from the consulting engineer (Mr. R. P. Wilson), 66, Victoria-street, Westminster, S.W., or from the borough engineer and surveyor (Mr. A. Angell) Tenders to the clerk (Mr. F. Stevens) by 4 p.m of July 16. See advertisement.

Grays Thurrock District Council require tenders for electricity generating plant, particulars of which are set out in an advertisement. Specification, &c, can be obtained, after July 2, at the offices of the consulting engineers (Messrs. Preece & Cardew), 13, Queen Anne's-gate, Westminster, S.W. Tenders must be delivered at the office of the clerk (Mr. Chas. E. Hatten) by noon of Aug. 9.

Croydon Corporation invite tenders for the reconstruction of the present tramway track and the construction of new tramways and paving of roads. Specification, &c., can be obtained at the offices of the town clerk, Town Hall, Croydon, after June 25, and all further particulars can be had from the engineer (Mr. E. W. Monkhouse), 14, Old Queen-street, Westminster, S.W. Tenders must be sent to Mr. E. Mawdsley, town clerk, Town Hall, Croydon, by 12 noon of July 10.

Huddersfield Corporation Electricity committee invite tenders for a single-phase steam-generating plant of 1,000kw. capacity. Specifications, &c., can be obtained from Mr. A. B. Mountain, borough electrical engineer, Electricity Works, St. Andrew's-road, Huddersfield, and tenders must be sent to Mr. F. C. Lloyd, town clerk, Town Hall, Huddersfield, by Thursday, July 12.

Extension of Time.—The date for tenders for the overhead equipment for about 16 miles of equivalent single track of tramways, for the Corporation of *Durban*, Natal, has been extended. Tenders (in duplicate) to Messrs. Webster, Steel and Co., 5, East India-avenue, London, E.C., by July 20, or to town clerk, Durban, on or about Monday, Aug. 13.

Swansea Corporation require tenders for main switchboard and instruments and a battery of accumulators and accessories. Tenders to consulting engineers (Messrs. Kincaid, Waller & Manville), 29, Great George-street, Westminster, by July 5.

Salford Corporation require tenders for overhead equipment for tramways, exclusive of steel poles. Tenders to town clerk by 10 a.m. July 16.

Limerick Corporation require tenders for the supply and erection of electrical plant and apparatus. Tenders to town clerk by July 14.

Edinburgh Corporation invite tenders for copper strip. Tenders to town clerk by July 9.

Blackpool Corporation invite tenders for trolley poles, cables, and trolley wire, boosters, and switchboards and a storage battery. Tenders to chairman Electric Lighting and Tramways committee by July 23.

Aron Electricity Meter (Ltd.), 46, Upper Thames-street, London, E.C., require tenders for the supply and delivery of large and small metal cases. Tenders by noon July 2.

Warrington Corporation invite tenders for the installation of the electric light in the town hall, bank house, museum, school of art, &c. Specification from Mr. W. H. Grimsdale, Bank House.

London County Council require tenders for the supply (within three months of order) of about 70 arc lamp standards for lighting Victoria Embankment. Tenders to clerk (Mr. C. J. Stewart) by July 10.

Trimdon (Co. Durham) Parish Council invite tenders for public lighting by electricity or acetylene gas. Tenders by July 17.

Hackney (London) Electric Light committee require tenders for 220 arc lamp pillars. Tenders to clerk by July 11.

Tottenham Council invite tenders for fire alarm posts and instruments, &c. Tenders to clerk by July 3.

Southend Council invite tenders for about 1,180 tons of steel rails and about 46 tons of steel fish-plates. Tenders to town clerk by July 25.

Leeds Corporation require tenders for supplying and erecting two, four or six steel boilers at their Crown Point generating station. Tenders to town clerk by July 9.

Whitehaven Corporation require tenders for stores, including electric fittings, incandescent lamps, &c. Tenders to town clerk by 30th inst.

Cardiff Corporation require tenders for about 1,000 tons of steel tramway rails, fish-plates, sole plates, tie bars, bolts and nuts, points and crossings, drain rails, copper rail bonds, &c. Tenders to town clerk by July 12.

Tenders are required for wiring the *Stockport* Technical School. Tenders to gas and electricity office, Portwood, by July 5.

Tenders will be awarded on Aug. 18 next for a concession to construct and work a system of electric tramways on the overhead trolley system at *Barcelona* (Spain). Particulars relating to this matter can be consulted at the Commercial Intelligence Branch of the Board of Trade, 50, Parliament-street, London, S.W.

Tenders are also invited for a concession for establishing and working for 20 years electricity supply for the town of *Lora del Rio*, Seville (Spain). This contract is to be awarded on July 5. Particulars relating to this tender are also to be obtained at the Commercial Intelligence Branch of the Board of Trade in London.

Tenders are invited until July 21 by the municipal authorities of *Algemesi* (Valencia, Spain) for the concession for electric lighting for 10 years. Tenders to El Secretario del Ayuntamiento.

Tenders are invited until July 14 by the municipal authorities of *Jumet* (Belgium) for the concession for electric lighting.

TENDERS RECEIVED AND ACCEPTED.

Watford District Council have accepted the tender of Messrs. S. Z. de Ferranti (Ltd.) for a 300 k.w. steam alternator at £3,150 Plant to be delivered, and in running order, within four months from date of order. The tender of Messrs. Babcock & Wilcox for an additional boiler, at £930, is also recommended.

Dundee Town Council have accepted the tender of Messrs. Hiley & Orchar for wiring the new fire brigade station at £50.

Luton Council have accepted the tender of Messrs. Main, Kendal & Main, Loughborough, for the erection of electricity station buildings at £4,175.

The Hammersmith (London) Vestry have accepted the tender of Messrs. Johnson and Phillips for the supply of twelve 25kw. transformers at £63 each.

APPOINTMENTS VACANT AND FILLED.

The following appointments are vacant at the Northampton Institute, Clerkenwell, London, E.C.: Senior lecturer and assistant in the mechanical engineering department, a junior demonstrator, a junior technical assistant, a junior lecture assistant and an optical demonstrator in the electrical engineering and applied physics department. Applications to the principal (Dr. R. Mullineux Walmsley). See advertisement.

Derby Technical Educational committee require lecturers and demonstrators in mechanical engineering, and in physics and electrical engineering for their municipal technical college. An advertisement gives further information, and applications must be sent to the principal by July 9.

Swansea Corporation require a resident electrical engineer to take charge, under the superintendence of the consulting engineers (Messrs. Kincaid, Waller & Manville), of the erection of electricity generating plant and the laying of electric mains. An advertisement contains further particulars, and applications must be delivered to the town clerk (Mr. Jno. Thomas), Guildhall, Swansea, by July 9.

Digitized by Google

The directors of the Johnson-Lundell Electric Traction Co. (Ltd.) invite applications for the position of general manager. Particulars are given in an advertisement, and applications are to be made in writing to Mr. Leonard W. Holmes, 17, Soho-square, London, W.

A Council in the South of England about to erect electric lighting plant require an engineer capable of advising and superintending a small generating station. See Advertisement.

Several test clerks are required for the Glasgow Corporation telephone department. Particulars from the consulting engineer (Mr. A. R. Bennett), Castle Chambers, West Regent-street, Glasgow. See advertisement.

Norwich Technical Instruction committee require an assistant lecturer and demonstrator in physics and electrical engineering. Applications to principal (Mr. Wm. Gannon, M.A.) by July 6.

The Vestry of St. John, Hampstead (London) require an assistant electrical engineer. Applications to vestry clerk by July 2.

The Council of the King's College, London, invite applications for the post of demonstrator in electrical engineering. Conditions of appointment from Secretary, and applications by 30th inst.

An assistant electrical engineer is required for the County Asylum, Wittingham, Lancs. Applications to medical superintendent.

Salford Corporation require a clerk of works on their new Strawberry-road electricity station building. Applications to town clerk by 30th inst.

British Electric Traction Co. require additional secretaries and accountants for its subsidiary companies. Application to secretary, Donington House, Norfolk-street, London, W.C.

The Council of the University College of North Wales, Bangor, have appointed Mr. W. W. Firth, B.Sc, formerly Whitworth Exhibitioner, to the assistant lectureship in electrical engineering, which the college has been enabled to establish by the liberality of the Drapers' company. Mr. Firth commended his career in the works of Messrs. Platt, at Oldham, and was trained at Owens College, Manchester, and the Royal College of Science, London.

Mr. G. C. Lamb, demonstrator at the Engineering Laboratory of Cambridge University, has been appointed electrical inspector by the Cambridge Corporation. Mr. Lamb has undertaken to make tests of electrical pressure at consumers' terminals at a nominal fee of £5. 5s. per annum (to be paid by the Corporation) with an additional fee of 10s. 6d. for each test, to be paid by the consumer.

Mr. Dunton has been appointed resident electrical engineer at Whitehaven, in succession to Mr. J. G. Scott, who is going to Leith. The commencing salary is £150 per annum, and Mr. Dunton has entered into an agreement to remain with the Council for three years.

Mr. H. J. Robinson, at present with the Dublin United Tramways Co., has been appointed chief assistant electrical engineer to the Pembroke (Dublin) District Council.

BUSINESS NOTICES.

In connection with the recent formation of the Johnson Lundell Electric Traction Co. (Ltd.), we understand that the financial arrangements are now completed and the organisation of the works is being rapidly perfected. Mr. C. Tilley has been appointed secretary and Mr. A. F. Hall engineer to the company. Mr. Hall has had a large experience in the States, and was chief draughtsman to Mr. H. F. Parshall at the time when the latter was engaged in designing the big generators of the General Electric Co. of New York.

An advertisement in the daily papers referring to the sale of certain leasehold property in St. Martin's-lane and Charing Cross-road, London, W.C., has conveyed the impression that the Electrical Standardising, Testing and Training Institution is removing from Faraday House. The secretary, Mr. H. Foulds, writes to say that the institution holds a long lease of its present premises which it is intended to exhaust. The sale of the superior lease therefore does not affect the institution.

In order to cope with increasing business in the London district the Sunbeam Lamp Co. are opening offices at 141, Fenchurch-street, E.C. Mr. E. J. Hogan, who has for many years managed their business under the company's late agents, has been appointed London manager. Letters and other communications should be sent to the new address after 30th inst., when the present agency expires. The telegraphic address is "Outshine London," the telephone number 313 Avenue.

BANKRUPTCIES, LIQUIDATIONS, &c.

The discharge of J. A. Hirst, electrical engineer (lately trading with Jas. Fletcher as Fletcher, Hirst & Co.) at Burnley, Chester and Derby, is suspended for two years.

In the bankruptcy of H. L. Howard (trading as Thompson, Howard & Co.), electrical and mechanical engineer, at Harrogate, York, and Hull, a first and final dividend of 4⅜d. is payable on July 5, at the O.R.'s, 28, Stangate, York.

A meeting of the creditors of George H. Bentley, 63, Cross-lane, Earlestown, formerly carrying on business as electrical engineer, was held last week at the O.R's office, Manchester. The gross liabilities were returned at £1,162, of which £1,147 is expected to rank for dividend; deficiency £308. Failure is attributed to losses on contracts and failure of an engine. Mr. G. F. Clarke, Earlestown, was appointed trustee, with a committee of inspection.

At the London Bankruptcy Court an application was made to Mr. Registrar Brougham for the approval of a scheme for the arrangement of the affairs of John E. Liardet, 16, Hyde Park-gate, W., and the Old Mill Works, Cowley. Debtor had been engaged in experimenting with and developing electrical, marine, and hydraulic patents since 1887. He failed in Dec., 1898, with liabilities £13,259, against assets valued at £19,000 upon a fair realisation. It was proposed to form the Motors and Mechanical Appliances (Ltd.) to deal with debtor's patents and inventions, and a scheme of arrangement had been accepted by the creditors under which they were to receive a cash composition of 7s. 6d. in the £, or cumulative preference shares in the proposed company to the full amount of their claims. The Official Receiver reported there was no evidence to show that the shares would afford reasonable security for the payment of 7s. 6d. in the £ to the creditors. Debtor contended that the fact that the creditors, with one exception, had elected to take shares instead of cash was sufficient evidence that the security would yield not less than 7s. 6d. The Registrar adjourned the case for a week.

The estates of William Ramsay & Co., electrical engineers, &c., 195½, Argyle-street, and 11, Jamaica-street, Glasgow, and William Ramsay and William Chalmers, the individual partners thereof, were sequestrated on June 19. A meeting to elect trustee and commissioners will be held on July 3 at the Faculty Hall, St. George's-place, Glasgow.

It has been decided to wind up the Improved Electric Glow Lamp Co. (Ltd.) voluntarily. Mr. F. F. Fuller is liquidator.

It has been decided to wind up voluntarily the Sandycroft Foundry and Engine Works Co. (Ltd.) for purposes of reconstruction. The secretary (Mr. F. H. Williams) is liquidator.

Sale by Auction.—Messrs. Wheatley Kirk, Price & Co. will sell by auction at the Grays Engineering Works, Grays, Essex, on Tuesday, Wednesday and Thursday next (July 3, 4 and 5), at 10 a.m. for 11 a.m. prompt, a large quantity of modern fixed and loose plant, machinery, utensils, stock, stores and other effects. Admission is by catalogue, which can be obtained (price 6d.) at the works; of Messrs. Hatten & Asplin, solicitors, Bank-buildings, Grays; or of the Auctioneers, 49, Queen Victoria-street, London, E.C., and Albert-chambers, Albert-square, Manchester. Some further particulars are given in an advertisement.

Plant for Sale.—As announced in an advertisement, the business, premises, plant, &c., of the Acetylite (Ltd.), 400, New John-street West, Birmingham, are for disposal. Particulars can be obtained from Messrs. Wragge & Co., solicitors, Bennett's-hill, and of the liquidator, Mr. E. M. Sharp (Messrs. Sharp, Parsons & Co.), chartered accountants, Colmore-row, Birmingham.

Westinghouse Electric Tramway Equipment.—A well-illustrated pamphlet describing a number of electric tramways in Great Britain equipped, partly equipped, and in course of equipment by the British Westinghouse Electric & Manufacturing Co. (Ltd.), has just been issued. The complete equipments supplied are those to Aberdeen, Bradford, Coventry, Glasgow, Halifax, Hull, Liverpool, Norwich, Plymouth, Southampton, and Swansea, and the plant, &c., now under order is for Manchester and Newcastle. Partial Westinghouse equipment has been supplied to Bath, Darwen, St. Helens, Salford, &c.

B.T.H. Plant.—Pamphlets Nos. 66 67, and 68 of the British Thomson-Houston Co. describe and illustrate direct-current fan motors, the GE_{59} traction motor, and the B.T.H. maximum demand meter respectively.

Fire.—A small fire occurred on the works premises of Messrs. Siemens Bros. & Co. at Bowater-road, Woolwich, on Sunday. As usual, the halfpenny papers made the most of a very small affair. The fire which occurred in the T block, and was confined to that portion of the works was practically subdued by Messrs. Siemens' workmen before the brigade arrived. The company's business will be in no way interfered with.

Jubilee.—Messrs. Wheatley Kirk, Price & Co., valuers, &c., of London and Manchester, on the 22nd inst. celebrated the jubilee of the firm by giving the whole of the London and Manchester staff a holiday trip up the river Thames, the partners entertaining the staff afterwards to dinner, at which the senior partner (Mr. Henry Sherley-Price) presided, supported by Mr. S. Sherley-Price, Mr. Ernest Sherley-Price, and Mr. John Place.

Digitized by Google

Exports of Electrical Apparatus and Material.—The following list gives official particulars of the exports of British manufactured electrical apparatus and material (including telegraph and telephone wire and material, but not including electrical instruments or machines, which are not separately specified) from June 20 to June 26, with the ports of destination :—

Africa—Algoa Bay, £102; Cape Town, £108; Durban, £285; East London, £23. *Australasia*—Adelaide, £30; Fremantle, £40; Melbourne, £152 (including £69 telegraph material); Sydney, £238; Townsville, £105. *Belgium*—Antwerp, £711. *Borneo*—Labuan, £61 (telegraph material). *Ceylon*—Colombo, £324. *China*—Shanghai, £366; Tientsin, £30. *France*—Calais, £28. *Germany*—Hamburg, £20. *Gibraltar*, £162. *Holland*—Amsterdam, £45. *Hong Kong*, £377. *India*—Bombay, £411; Calcutta, £678 (including £584 telegraph wire). *Japan*—Nagasaki, £12,000 (telegraph cable). *Russia*—St. Petersburg, £855 (including £505 telegraph wire). *Straits Settlements*—Penang, £37 (telegraph material). *Sweden*—Stockholm, £33. *United States*—New York, £12,700 (telegraph cable). *West Indies*—Trinidad, £40. Total £30,515, against £7,093 in the corresponding week last year (June 21 to 27).

PATENT RECORD.

The following list of Applications for Patents and Specifications published has been compiled for this journal by Messrs. J. C. Chapman and Co., *Chartered Patent Agents, of 70, Chancery-lane, W.C., from whom any available information in connection with Patents, Designs, and Trade Marks may be obtained.*

APPLICATIONS FOR PATENTS.

Note.—*The undermentioned Applications are not open to public inspection until after the acceptance of the complete Specification. The names within parentheses are those of communicators of inventions. When complete specification accompanies application, an asterisk is affixed.*

April 10, 1900.

6,704. C. Vogt. London. Improvements in induction apparatus.*
6,727. J. A. Halford. London. Improvements in electric contacts.
6,728. J. A. Halford. London. Improvements in electric contacts.
6,731. W. L. Wise. London. Combined telephone exchange and alarm systems. (A. Goldstein and J. M. Latimer, United States.)
6,748. F. M. Lewis. London. A new or improved alternating-current electro-motor.

April 11, 1900.

6,774. W. L. Spence. Alloa. Improvements in or connected with direct current transformers.
6,780. H. H. Lindon and R. F. Collinge. Liverpool. Improved electrical measuring instruments.
6,793. F. G. Tolchard. Paignton. Automatic regulating switch.
6,794. A. Eckstein and A. J. D. Krause. Manchester. An improved electrical combined switch and cut-out.
6,795. C. B. Ketley. Birmingham. Improvements in phonographs and graphophones.
6,798. S. M. Johnstone. Glasgow. Double and single-pole maximum and minimum automatic electrical cut-out.
6,826. J. C. de Janisch. London. Improvements in switches for electric currents.
6,828. M. Mildner. London. Improvements in the manufacture of electric cables, more particularly intended for conducting currents of high tension or voltage.*

April 12, 1900.

6,866. W. L. Spence. Alloa. Improvements in or connected with electricity distribution on the multiple voltage system.
6,878. H. V. James. Manchester. Improvements in electric arc lamps.*
6,893. W. Bohne. London. Improvements in phonographs.*
6,913. The British Thomson-Houston Co. (Ltd.), and F. Holden. London. Improvements in electrical speed indicators.
6,918. W. C. E. Faber. London. An improved electric typewriter.
6,923. C. F. Dussaud. London. Improvements in loud-speaking telephones.
6,931. J. G. Lorrain. London. Improvements in or connected with the transmission and distribution of electricity. (F. Bedell, United States.)
6,936. E. F. Moy and E. F. Moy (Ltd.). London. Improvements in switches for electrical circuits.

SPECIFICATIONS PUBLISHED.

Note.—All Specifications can now be obtained at the uniform price of 8d. each.

1899.

516. Muirhead. Telegraphic receiving and translating instruments.
7,525. Muirhead. Telegraphic transmitting, receiving and translating arrangements.
9,989. Mavor. Governing of engines used for driving electric generators in electric distributing systems.
7,918. Heys (Dumoulin). Manufacture or production of bands and strips of copper and other metals by electrolysis on rotary mandrels.
10,406. Miller. Wireless telegraphy.
11,678. Thompson (Becker). Electrolytic apparatuses for extracting metals lighter than the electrolyte.
11,985. Smith. Overhead conductors for electric tramways.
12,165. Still. Electric motors.
12,417. Wynne. Supports for conductors for electric railways.
12,627. Andreas. Manufacture of electric battery plates.
17,211. Wheatley (Wohlgemuth). Holder for telephones.
17,319. The Steel Nut and Joseph Hampton (Ltd.) and Hampton. Grips used in the laying of underground electrical cables.
18,132. Getty. Clocks, more particularly in electric winding, mechanism therefor.
25,446. British Thomson-Houston Co. (Ltd.) (Priest). Electric railway motors.
25,447. British Thomson-Houston Co. (Ltd.) (Case). Brakes for electric railway vehicles and the like.
25,448. British Thomson-Houston Co. (Ltd.) (Case). Controllers of electric motors.

COMPANIES' MEETINGS AND REPORTS.

Electric and General Investment Co. (Ltd.).

The eleventh ordinary general meeting was held on Tuesday, Mr. George Herring in the chair.

The SECRETARY (Mr. J. Cecil Bull) read the notice calling the meeting, and the report and accounts were taken as read.

The CHAIRMAN then said: Gentleman, from the balance sheet you will see that, as regards the amount of capital, the figures are the same, while the provision for contingencies shows an increase of £11,450 as compared with last year. The loan account is £35,000, which is money borrowed against our securities, and I may say here, that we frequently have to pass very good business in consequence of the smallness of our capital. The next item, "sundry creditors," is £9,390. These creditors are merely a sort of book entry. That is to say, on the date of making up the accounts they were creditors, but they are constantly changing. The item of "unclaimed dividends" speaks for itself, as does also the balance of profit and loss. On the other side there is the item of "investments at cost." In consequence of the securities being of an electrical character and the market not being in as good a state as formerly, I cannot say to you to-day, as I have done on previous occasions, that they are worth a *great* deal more than the figure at which they stand in our books, but I can assure you of one thing, and that is that you may safely reckon that they are worth the amount placed against them, *and more*. The item "sundry debtors" is merely a question of what was on our books on May 31st, and I am happy to say that since the company was formed we have never made a bad debt. The cash at Parr's Bank speaks for itself. Coming to the profit and loss account, we have General Charges, Interim Dividend, and on the other side Profit on the issues made, &c., amounting to £19,796. That is a pretty good profit to make on a small capital of £20,000. Still, it is £11,948 less gross profit than we made last year, but I told you then that you could not expect we should keep up the profit at that rate. With regard to one of our children—of which we are very proud—there are a few words that I should like to say to you. I refer to the British Electric Traction Co. In 1898, in addressing you on a similar occasion to the present, I made use of these words: In my speech at the last meeting I did a little boasting. I said: "The next company we started was the "Pioneer British Electric Traction Co. That we turned in the past financial year into the present British Electric Traction Co. I do not think "we shall have to wait quite so long for that to arrive at maturity. My hope "and my belief is that it will progress faster than any other, and I think "that if I live a few years, and remain your chairman, I shall be able to "point with great pride to the British Electric Traction Co. It is not "dealing with an unknown experiment—it is a thing that has been proved, "and over $50,000,000 has been put into this same traction business in "America. It has also been proved and been a great success in Germany, "and I have no doubt in my own mind that when it gets into good working "order here it will be just as brilliant a success."

Now, gentlemen, I am rather proud of that prophesy, for it has got into working order, and I am sure that it will be a brilliant success. The splendid work done by that company has been largely due to my colleague, Mr. Garcke, and if he were to speak he would tell you that the British Electric Traction Co. has only just commenced its great career.

England, Ireland, Scotland and Wales are particularly adapted to the electrical mode of travelling because of the density of the population, and yet Great Britain has only about 200 miles of electric traction lines, while America has over 17,000, and nearly every company in America is, I believe, paying well. In Germany electric traction has been very fairly developed, and there, too, it is paying well; but in this country we are only just commencing. There are hundreds of millions of money invested in gold mines in South Africa, and yet in this industry we have a gold mine right in front of us which has only to be properly looked after to pay well, and is not subject to the danger of "giving out" at any time because, as the population increases, so will the traffics. I would go so far as to say that it is nearly impossible to imagine an electrical tramway properly managed, situated in the midst of some populous town or district, which would not pay a good dividend. The debentures that we issue in the subsidiary companies pay 4½ per cent., and I make

Digitized by Google

bold to say that they are as well secured as railway debentures which yield only 3 per cent., while the preference shares pay 5 per cent. I do not not care to prophesy as to what the ordinary shares will pay. You may say, "Why talk about the British Electric Traction Co. instead of our own?" It is because we are bringing out constantly the subsidiary companies for the British Electric Traction Co., and we are particularly anxious that it should be well known that those companies are good and sound properties. It is generally remarked, "Yes, that is all very well, but you are always asking for money." I plead guilty to that, and say that we shall have to keep on asking for money, because it will require millions to complete the orders that the British Electric Traction Co. have, and many millions more to thoroughly equip Great Britain with electrical traction. We make a profit out of these issues, and therefore it is to the benefit of the shareholders in this company to interest as many of their friends as they can in the goodness and value of this electrical business. I now move the adoption of the report and accounts and the appropriation of the profits as recommended by the directors.

Mr. J. B. BRAITHWAITE seconded the motion, and no question being asked it was at once carried unanimously.

Mr. George Herring was re-elected a director, and after the re-appointment of Mr. G. T. Rait as auditor, a vote of thanks to the chairman and directors terminated the proceedings.

Bastian Meter Co. (Ltd.).

The third ordinary general meeting of this company was held yesterday (Thursday) at the works. Mr. C. ORME BASTIAN, chairman and managing director, presided.

The SECRETARY (Mr. S. Robins) read the notice calling the meeting.

The CHAIRMAN said the results of the past year could be summed up in the words "rapid progress." They had converted a loss in 1899 of over £2,000 into a profit of nearly £400. This profit, though not startling, was enough to pay the dividend on their small preference issue several times over. How far they had progressed might be gauged from the fact that they had taken orders for more meters in the past three weeks than they did in the whole of the first six months of the year. Although their output had increased so rapidly their wages bill every week actually amounted to a smaller sum than was the case this time last year, due to the fact that the workpeople had now well learnt their duties and everything was being conducted on methodical lines. They had been very fortunate in securing the sole right to make and sell the Rimington maximum demand indicator, an instrument that worked in conjunction with their meter, showing the discount or rebate to which a consumer of electricity was entitled on his quarterly account. Thousands of these instruments were sold every year, and Mr. Rimington's invention possessed many advantages over other instruments on the market. He believed the holders of ordinary shares would soon receive ample reward for their patience. The directors were most sanguine as to the future. The Company had not yet sold a single foreign patent. The German licence had been granted on a royalty basis, with a substantial minimum annual payment. The directors had decided to waive their claim to fees for the past year. He concluded by moving the adoption of the report and accounts.

"*That the report of the directors produced, together with the annexed statement of accounts to February 28, 1900, duly audited, be now received, approved, and adopted.*"

Mr. UMBERTO CIANTAR seconded the motion, which was carried unanimously.

The retiring director (Mr. C. Orme Bastian) was re-elected, and the auditors re-appointed.

A vote of thanks to the chairman and directors terminated the proceedings.

United River Plate Telephone Co. (Ltd.).

The report of the directors for the year ended March 31 last states that the gross receipts in the River Plate were £101,169. 17s. 4d., against £85,248. 16s. 10d. for the previous year, and the working expenses in London and the River Plate £50,335. 9s. 9d. After deducting debenture interest and interim dividends, and adding transfer fees and interest on investments, and £7,889. 11s. 4d. brought forward, there remains a balance of £43,069. 5s. 6d. The directors propose to transfer £5,000 to depreciation fund and £20,000 to reserve, and recommend a final dividend of 4½ per cent. on the ordinary shares, making, with the interim, 7 per cent. for the year, carrying forward £5,019. 5s. 6d.

Continued increase in the business of the company requires large extensions in the plant at Buenos Ayres, a considerable portion of which will be permanent and underground. For this purpose the directors consider it advisable to make an early issue of the remaining 5 per cent. cumulative preference shares.

West African Telegraph Co. (Ltd.).

The report of the directors for the year ended Dec. 31 states that the revenue for that period amounted to £77,008. 4s. 6d., against which £20,297. 14s. 10d. is charged for ordinary expenses, and £11,482. 9s. 11d. for expenditure relating to repairs of cables, &c. After providing £328. 10s. 3d. for income tax, there remains £44,899. 9s. 6d., to which is added £2,179. 5s. 2d. from preceding year, making £47,078. 14s. 8d. From this sum there has been deducted £8,746. 14s. 7d. for debenture interest, and £15,033. 6s. 8d. for sinking fund, leaving £23,298. 13s. 5d., out of which the directors propose to place £23,000 to general reserve and to carry £298. 13s. 5d. forward.

The revenue for the year includes a further £12,000 in respect of subsidy due from the French Government, but which has not yet been paid. This arrear, together with the sums withheld in previous years, now amounts to £55,415. The directors, with a view to assimilate the working of the company to that of the allied companies, have considered the advisability of establishing staff pension and superannuation funds. Details have been worked out by the actuary of the already existing funds of the associated telegraph companies and a formal resolution will be submitted at the forthcoming meeting empowering the directors to carry out the necessary arrangements.

NEW COMPANIES, STATUTORY RETURNS, &c.

CINQUE PORTS LIGHT RAILWAYS (LTD.)—This company was registered on June 16, with a capital of £25,000 in £1 shares, to continue and support the application under the Light Railways Act for authority to construct the Cinque Ports Light Railway, and to carry on the business of railway and general engineers, railway and tramway proprietors, &c.

MANGANO ELECTRIC PROCESS (LTD.)—This company was registered on June 15, with a capital of £50,000, in £1 shares, to carry on generally the business of electrical engineers, electricians, and suppliers of electricity, and in particular to acquire and exploit the interest and rights of MM. G. E. Bourgoin and H. Lavollay in a certain invention for the epuration and decolouration of sugar by the Mangano electric process. The subscribers are F. Witting, C.E., A. Holliope, L. A. Price, E. F. Trone, G. F. Franks, W. Bullock, engineer, and F. C. Bell.

NORTHWOOD ELECTRIC LIGHT AND POWER CO. (LTD.)—This company was registered on June 23, with a capital of £15,000, in £1 shares, to carry on at Northwood, Ruislip, Middlesex, or elsewhere, the business of electricians, mechanical and electrical engineers, suppliers of electricity, manufacturers of electrical machinery and apparatus, &c. The subscribers, with one share each, are J. S. Hignett, A. T. Bucknall, A. H. Crossley, D.Sc., C. E. Masterman, C.E., C. H. Wickes, R. Crossley, and J. W. Tilley.

ROUNDHAY AND DISTRICT ELECTRIC LIGHTING CO. (LTD.)—This company was registered on June 22, with a capital of £20,000, in £10 shares, to carry on the business of electrical and general engineers, electricians, suppliers of electricity, &c., at Roundhay and Seacroft, near Leeds, or elsewhere. The subscribers are M. Kitchin, C. Lupton, W. P. Green (engineer), J. E. Whiting, W. Harvey, W. S. Sykes, and A. G. Lupton. The first directors are M. Kitchin, J. E. Whiting, and W. P. Green.

CITY NOTES.

MEMORANDA.—Bank rate 3 per cent. (since June 14, 1900). Price of silver 28 $\frac{15}{16}$d. per oz. (June 28). Consols (2¾ per cent.) 100$\frac{5}{8}$—100$\frac{7}{8}$ for money, 100$\frac{1}{16}$—100$\frac{3}{16}$ for account; 2½ per cent. 99$\frac{1}{2}$—99$\frac{3}{4}$ (June 28). Stock Exchange Settling Day: Consols, July 4; Stocks and Shares Continuation Days, July 10 and 25; Ticket Days, July 11 and 26; Pay Day, July 12; Mining Share Carry-over Days, July 9 and 24.

INDO-EUROPEAN TELEGRAPH CO. (LTD.)—This company is prepared to receive requisitions for the seventh series of coupons to be issued to holders of share warrants to bearer in this country.

KALGOORLIE ELECTRIC POWER & LIGHTING CORPORATION (LTD.)—The directors have issued a circular giving particulars of the progress made since the statutory meeting. After some delay the lease has been transferred from the Kalgoorlie Power Syndicate to the corporation, and hoisting and pumping plant has been erected. Mr. G. R. Mair, who has been since 1888 with the General Electric Co. of America, has been appointed constructing engineer. The board invited tenders for engines from the principal European and American manufacturers, and after careful consideration the contract was awarded to Messrs. D. Stewart & Co. (Ltd.), Glasgow. The engines contracted for are of the vertical cross-compound type with Corliss valve gear, these having special suitability to the conditions existing at Kalgoorlie. Contracts have been placed for generators with the General Electric Co. of New York. This company sent in the lowest tender and offered apparatus which conformed with the corporation's specification in all essential points. Mr. Mair has left for Kalgoorlie to make preparations for the installation of the plant.

CALCUTTA ELECTRIC SUPPLY CORPORATION (LTD.)—The directors have offered to the shareholders for subscription 10,000 shares of £5 each, at £5. 10s. The shares are offered *pro rata* to existing members in proportion of one share for every two shares now held. Allotment will be made on July 18.

ISLE OF MAN TRAMWAYS & ELECTRIC POWER CO. (LTD.)—A meeting of the new board of directors is, it is said, being held in Manchester this week with the object of obtaining the support of holders of the company's bills to a scheme for continuing the company and preventing its being wound up. It is stated that, should the board find that Dumbell's Bank have endorsed those bills, the directors will consider any further attempt to save the company as hopeless.

LIVERPOOL OVERHEAD RAILWAY CO.—This company are inviting subscriptions to an issue of 5,000 ordinary shares of £10 each, at £8 per share, to provide capital for the electrical equipment of the tramways leased to the company by the Waterloo-with-Seaforth and Great Crosby District Councils, for additional rolling stock, &c. The issue is limited to shareholders, and closes to-morrow (Saturday).

Digitized by Google

MARCONI'S INTERNATIONAL MARINE COMMUNICATION CO. (LTD.)—The 350,000 £1 shares in this company are now being offered to shareholders in Marconi's Wireless Telegraph Co. (Ltd.). Mr. Marconi has accepted the position of technical adviser to the company for three years, with a seat on the board.

SIEMENS AND HALSKE AKTIENGESELLSCHAFT.—It is reported that the directors propose to declare a dividend of 10 per cent. for the year ending July 31, the same as last year.

STOCK EXCHANGE NOTICE.—The Stock Exchange committee has been asked to allow 15,000 ordinary £5 fully-paid shares, 10,000 6 per cent. £5 first preference shares, 10,000 5 per cent. £5 second preference shares, and 90,000 4 per cent. debenture stock of the *Kensington and Knightsbridge Electric Lighting Co. (Ltd.)* to be quoted in the official list.

THOMAS PARKER (LTD.)—The directors' report, just issued, is short and to the purpose. It states that they consider the statement of accounts "thoroughly satisfactory." After writing of depreciations, the balance standing to credit of profit and loss is £14,135. 10s. 7d.; out of this a dividend at the rate of 10 per cent. per annum, less tax, is to be paid, £5,000 placed to reserve (bringing it to £15,000), and the balance is carried forward.

TYPEWRITING TELEGRAPH CORPORATION (LTD.)—This week subscriptions have been invited to an issue of 53,334 ordinary shares in this corporation, of £1 each, which has been formed to acquire letters patent in respect of certain improvements in telegraph recording instruments invented by Mr. W. S. Steljes, the business connected with the same as a going concern, and a number of contracts. Reference was made to these instruments on page 39 of *The Electrician* for May 4, and elsewhere in this issue a technical illustrated description will be found. The prospectus under review states "that all necessary agreements with the Postmaster-General have been entered into," and sets out particulars of important agreements with the National Telephone Co. for the use of Steljes' apparatus on the company's lines, and with the Exchange Telegraph Co. Reports accompany the prospectus from Mr. C. E. Spagnoletti, who is a director of the company; the late Mr. W. Johnson, of Sheffield; Messrs. Fell and James, patent agents; and Mr. W. R. Bousfield, Q.C., M.P., as to the utility of the apparatus and the security of the patent rights. The prospectus contains full particulars of the contracts entered into, and contains no waiver clause. The purchase price is £55,000, payable as to £28,334 in cash and £22,666 in shares. It is estimated that £25,000 will be provided out of the present issue for working capital, and that £15,000 will be sufficient working capital as a minimum, below which latter sum the directors will not proceed to allotment. The list closed yesterday (Thursday).

NOTES.

MANY of our readers will learn with regret that the Dublin Electric Lighting Bill was thrown out on the motion for the third reading last Monday. After running the gauntlet of keen opposition at the hands of the Corporation of Dublin, and passing through the report stage with a majority of 13 votes, this bill, which is being promoted by the Dublin Electric Lighting Co., has met with this unhappy fate. The result is, however, to be regarded rather as a curiosity in Irish politics than as any important development in sober electrical engineering. In a leading article on April 13th we commented on the rival schemes for electric supply at Dublin, viz., the combined electric lighting and tramway scheme of the company and the polyphase scheme for electric lighting alone brought forward by the Corporation. The result of the rejection of this bill, we presume, will be that Dublin will be supplied with electric light from a municipal polyphase station, while its extensive system of tramways will be run by the company from an independent power house. Considering that this result has been brought about by municipal opposition, the local authorities who have made combined electric lighting and tramway undertakings their principal argument in favour of municipal electricity works must feel somewhat disconcerted.

WE are told, however, that the rejection of the company's bill was necessitated in the interests of all local authorities owning electricity works. There is no precedent, it is said, for introducing company competition against a local authority already running electricity works. This, however, overlooks two important facts; firstly, that neither to local authorities nor to companies do the Electric Lighting Acts grant a monopoly—the terms of the acts state emphatically to the contrary; and, secondly, that the company proposed to do what the Dublin Corporation has long had an opportunity of itself doing had it so wished. Surely where, as in the case of Dublin, the municipal owners of a provisional order fail to develop the order to its fullest reasonable extent, it is only right that the Board of Trade should grant a competitive order to any responsible company prepared to undertake the work. This, indeed, is the situation at Dublin in a nutshell. It remains to be seen whether the Dublin Corporation, now that its prospective competitor is defeated, will carry out the big scheme of electrical supply it has displayed as its pretext for opposition.

INDUSTRIAL economists will watch with considerable interest the development of an experiment which is about to be made in the neighbourhood of Budapest, Hungary, in supplying electricity for motive power for industrial purposes in cottages and small homesteads. The feasability of this as an alternative to the existing factory system has more than once been advanced by prominent economists in this country. Lord SALISBURY, for example, has on several occasions expressed the opinion that the advent of electric power would revolutionise industrial methods, decentralising industry from the factory to the home. On the other hand, it has been shown that the factor of cheap power is not the sole consideration, nor indeed the principal consideration, in determining whether an industry should be carried on in a factory or in a number of isolated homesteads. Other considerations, such as the distribution of the raw material and the collection of the finished products enormously affect the question. It will be interesting, therefore, to see what degree of success is effected with the Hungarian experiment, which appears about to be made conjointly by the Ungarische Elektricitäts Allgemeine Gesellschaft and the Budapester Allgemeine Elektricitäts Gesellschaft.

THE strong centre of attraction afforded by the Paris Exhibition has brought a large number of American and Colonial engineers to this country on their way to Paris. It was in the fitness of things, therefore, that the 32nd Annual Convention of the American Society of Civil Engineers should be held in London. The convention opened on Monday last, at the Institute of Civil Engineers in Westminster, and was

Digitized by Google

brought to a close last night by a reception by the Institution of Civil Engineers at the Guildhall. The proceedings commenced with an address of welcome to the visitors from Sir DOUGLAS FOX, the President. In this address he referred to the competition in this country on the part of American engineers, and said we were ready for competition, and nothing was to be feared therefrom. He hoped that the visit of our American cousins would teach us how to meet this competition, and he extended a hearty welcome to these engineers who were meeting their English hosts on intimate terms of friendship and amity.

THE Papers dealt with during the convention were not of an electrical nature, and therefore call for little comment. Electrical engineers, however, may feel some interest in Mr. R. W. HUNT'S Paper on "Iron and Steel Rails," read on Tuesday last. The Paper considers the subject mainly from the American point of view, and deals mostly with American practice. In a historical summary, the author calls attention to the enormous production of American rails at the present time, one mill alone having turned out no less than 58,103 tons in a month. The question of standardisation of rail sections was dealt with, but the author would probably admit that we have brought standardisation to a higher pitch in this country than have the American ironmasters. The Paper included some account of the McKenna process for renewing old rails. The worn rails are re-heated to a temperature of about 1,500°F., and passed through re-forming rolls. They are then sawn hot and straightened cold. No less than 100,000 tons of rails thus treated are in use, which tends to prove the satisfactoriness of the process. Indeed, so much better do the rails appear to be after renewing that the author puts forward the somewhat paradoxical statement that "no rail ought to be used at all until it has been renewed," which reminds us of the Irishman who declared he could never put on a new boot until he had worn it a month.

A LETTER which we reprint from *Nature* this week announces the encouraging fact that the execution of the important work of bringing out an international catalogue of scientific literature is now practically assured. Whatever doubts there may have been prior to the recent conference as to the feasibility of this gigantic scheme appear to have been completely dissolved, and instead of meeting with almost insuperable obstacles and objections, the proposals of the English scientists were cordially accepted by their foreign *confrères*. All true lovers of science will wish that success may crown the efforts of the International Committee, but in order that these efforts may be successful the catalogue must meet with commercial as well as scientific patronage. The catalogue is to be published annually in 17 volumes, and is to include both an authors' and a subject index. It is admitted that if 300 sets or the equivalent are sold annually, the expenses of publication will be met. We hope that, for their credit's sake, the collective interest of civilised nations of the world in a great and complete compilation of scientific literature is capable of supporting an edition of 300 copies annually.

THE following report on the subject of gutta-percha extracted by what is known here as the Serullas process from the leaves of the *Isonandra Gutta* has been made by the French Administration of Posts and Telegraphs:—

A cable conductor, made with gutta-percha obtained from this source, had been kept from July, 1897, until March, 1898, at the Paris central depôt; it was then sent to the Seine cable factory, and was under observation until May 15, 1899, without variation of its insulation or various physical properties.

At this date it was covered with an armouring, and the cable thus constituted was submerged in the Seine dock. This cable, after being submerged for seven months, did not show any fall of insulation. It was picked up at the end of December, 1899, and placed under water in one of the tanks of the factory. This operation does not appear to have caused deterioration, and it still shows satisfactory insulation. Up to the present it has been admitted that gutta extracted from leaves gives a very high insulation, but that it is not stable and soon cracks. The tests referred to above, extending over two years, would seem to show that the preservation of this gutta is greater than was supposed. The period is, nevertheless, not sufficiently long to permit of definite conclusions. Gutta extracted from leaves presents, moreover, the inconvenience of being less fusible than ordinary percha, and much more difficult to work. Recent tests with joints of conductors thus constituted have, however, been made, and have given satisfactory results. In consequence of these various experiments, the Administration is about to order, using gutta extracted from leaves, a short cable which will be laid near the shore and employed in the service during the summer. It is unnecessary to say that, so far as submarine cables are concerned, the study of innovations must be made with the greatest caution, and that experiments should only be undertaken progressively.

In the report of the Commission formed to consider the question of the establishment of a system of French submarine telegraph lines, it is recommended that the new gutta-percha should be used for one at least of the short cables included in their programme, provided that those who supply the material guarantee it. It is added that the price of "leaf" gutta-percha would be considerably lower than that of the ordinary variety, say, 14fr. or 15fr., instead of 20fr. to 25fr. for the same quality. Nothing is said as to the quantity likely to be available.

AT the recent annual general meeting of the Incorporated Gas Institute, Mr. W. H. Y. WEBBER gave an interesting lecture under the somewhat misleading title, "The New Gas." Mr. WEBBER referred to the old proposal of supplying a fuel gas for heating purposes, and suggested that with the Welsbach burner such a gas could now be used in place of the present highly-carburetted gas. He cited some experiments made in Germany of supplying gas obtained directly from Westphalian coal, without enrichment. The illuminating power, when the gas was burnt in ordinary burners was, of course, much less than the present legal standard in this country, while the calorific value was not greatly altered. If the proposal were carried into effect, the ordinary gas burner would be even less economical than it is at present; and although the competition of the incandescent gas burner with the incandescent electric lamp might be keener, the electric light would then, without a doubt, be "the poor man's light."

Opening of the Swansea Tramways.—The mayor of Swansea performed the opening ceremony of these new tramways on Saturday last. The chairman and directors of the British Electric Traction Co. were present.

Personal.—We regret to learn that, owing to ill-health, Mr. Julius H. West has been compelled to resign the editorship of the *Elektrotechnische Zeitschrift*. We trust that Mr. West will speedily recover his health.

Electrical Engineers (R.E.) Volunteers in South Africa.—Sapper F. C Weakley is reported to have died of enteric fever at Viljoen's Drift on June 27. The death is also announced of Pte. E C. Short from enteric fever at Kroonstad.

American Electro-Therapeutic Association.—The tenth annual meeting of this Association will be held from Sept. 25 to 27, at the Academy of Medicine, New York City. The programme includes the following two items: (1) Electricity in Gynecology and the present reluctance of gynecologists to use Electricity, (2) Electricity in Tuberculosis and the present modes of Treatment. Further information may be obtained from the secretary, G. E. Bill, M.D., 255, North-street, Harrisburg, Pa.

American Electric Railway Statistics.—From a table of "Street and Elevated Railway Mileage, Cars and Capitalisation in United States and Canada, 1899," given in the June issue of the *Street Railway Journal* of America, we extract the following figures relating to electric railways:—

	Track mileage.		Motor cars.		Trail cars	
	1898.	1899.	1898.	1899.	1898.	1899.
United States	15,942	17,969	36,616	39,360	9,933	11,298
Canada	634	720	1,242	1,543	200	395

Cable Interruptions:—

	Date of Interruption.
Latakia—Cyprus	June 21, 1899
Cayenne—Pinhieros	Oct. 11, 1899
Tangier—Tarifa	Jan. 3, 1900
Paramaribo—Cayenne	Feb. 16, 1900
Ceara—Maranham	Feb. 20, 1900
Pará—Maranham	Mar. 2, 1900
Môle-St. Nicolas—Cap Haitien	Mar. 7, 1900
Gibraltar—Tangiers	June 28, 1900
Hong Kong—Macao	June 28, 1900

Honorary Degrees at Victoria University.—Last Saturday was degree day at Victoria University, and the Chancellor, Earl Spencer, conferred the honorary degree of Doctor of Science on Sir William Huggins, Sir W. C. Roberts-Austen, Sir William Abney, Dr. T. E. Thorpe, Profs. J. Dewar, A. R. Forsyth, E. Pickering, J. J. Thomson, A. Michelson, and H. A. Rowland, Lord Rayleigh, Mr. R. T. Glazebrook, and Mr. Henry Wilde. In addition, the honorary degree of D.Lit. was conferred on Mr. Sydney Lee.

Institution of Junior Engineers.—On Saturday the 14th inst., members of this Institution will visit Lord Rothschild's estate at Tring to inspect the electrical installation and other matters of interest. The train leaves Euston at 1:45 p.m. On Friday last the members visited the works of Messrs. Caird & Raynor, of Limehouse. This firm are well-known manufacturers of evaporators, condensers, feed heaters, pumps, &c. The motive power throughout the works is electrical, current being generated on the premises by a dynamo driven by a gas engine.

Institution of Mechanical Engineers.—As a surprise item not down on the official programme, the members of the Institution of Mechanical Engineers, on Thursday of last week, were treated to the reading of a Paper of peculiar interest at the present moment, entitled "Notes on the Construction of Long Cecil, a 4·1in. Rifled Breech-Loading Gun, in Kimberley during the Siege 1899-1900," by Mr. Edward Goffe, of Kimberley. The printed Paper is accompanied by an admirable photographic view of the gun, as well as a number of well-executed scale drawings of details.

Electrical Equipment of the New York Elevated Railways.—It is expected that the electrical equipment of these railways will be completed by Feb. 1, 1901. The committee, acting on the advice of their experts, have decided on the adoption of trains with a motor car at each end, each motor car being equipped with four motors and capable of hauling six coaches. Each motor will be of 100 H.P., thus giving 800 H.P. per train. The contract for the generating plant has been placed with the Westinghouse Company, and for the engines with the Allis Company. There are to be eight engines of 8,000 H.P. each capable, however, of working up to 12,000 H.P. on emergency. The boilers will be supplied by the Babcock & Wilcox Company. Up to the present the contracts entered into involve about £1,000,000.

Report of American Institute of Electrical Engineers, Committee on Electrical Units and Standards.—At the last Philadelphia meeting of the American Institute of Electrical Engineers, the Committee of Units and Standards, which had been formed on March 28th last, submitted their report. The reference to this Committee included the consideration of (1) Names of absolute units in electrostatic and electromagnetic systems; (2) the use of prefixes to denote multiples of these units; (3) the rationalisation of the present system by making the absolute unit of magnetism equal to the present magnetic line, and the absolute unit of magnetic potential-difference as equal to the present absolute unit of current-turn; and (4) the advisability of discussing these subjects at the Paris Congress. The Committee's report on these references were as follows:—(i.) Names for the absolute units are needed, as also suitable prefixes for decimal multiples and sub-multiples of these units; (ii.) the International Congress at Paris should be urged to decide on such names and prefixes; (iii.) rationalisation of units is urgently necessary, and the Congress be requested to consider the subject; and (iv.) the whole subject be discussed at the approaching general meeting of the Institute in Philadelphia.

Electric Power at the Westinghouse Air-Brake Works.—The American works of the Westinghouse Air-Brake Co. are now driven entirely by electric power. According to the *Electrical World*, a large central station has been erected at the works, and has been equipped with the most modern generating apparatus for this purpose. The plant consists of boilers of 2,000 H.P. capacity, which furnish steam for three Westinghouse-Parsons steam turbines. Each one of these turbines is direct connected to a bipolar, alternating-current generator, manufactured by the Westinghouse Electric & Manufacturing Co. The generators run at 3,600 revs. at a pressure of 400 volts. There are also two exciter units, the air pumps and condensers for the turbines, driven by a 50 H.P. motor, and two air compressors driven by 100 H.P. motors. The exciters deliver current at 110 volts. All the motors are of the Westinghouse induction type, placed in the most convenient situations, and belted to the original line shafts, which run at 112 revs. to 175 revs., an increase of about 12 per cent. in speed. Countershafts are largely dispensed with. In the machine shops there are motors aggregating 435 H.P.; in the boiler house, three motors, 60 H.P.; blacksmith shop, two motors, 50 H.P.; brass foundry, three motors, 35 H.P.; iron foundry, 13 motors, 185 H.P.; leather room, two motors, 25 H.P. Total motors 48, aggregating 790 H.P. There are 2,500 incandescent and 60 arc lamps of 100 hours' capacity, all taking current at 110 volts.

Utilisation of Energy Lost in Resistances.—A writer in the *Elektrotechnischer Anzeiger* of June 14, considers the question whether the energy lost in the regulating resistances of motors, and the steadying resistances of arc lamps cannot be usefully employed. In the case of resistances such as those in series with fan motors which are often kept running for a considerable period at less than their full speed, he suggests that low voltage lamps might take the place of the resistance coils, these lamps being in situations where momentary extinctions would not be of great importance. At the points where these lamps are, he proposes to place a second lamp fed by the full pressure of the mains, and the regulating switch of the motor is to be so arranged that as soon as the low voltage lamps (serving as resistance) were switched out, the ordinary voltage lamps would be switched in, the contacts of this switch being placed so that the two lamps could not be alight at once. In the case of arc lamps, he suggests the use of cooking or heating apparatus having the same resistance as the steadying resistance which could be switched on in place of the latter when required for use. He also proposes that fan motors and similar motors might be used in the same way. Arc lamp circuits and even incandescent lamps might be used for the same purpose where an unsteady light is permissible. This latter suggestion, however, hardly appears practicable, as the life of the lamps would be considerably shortened by the over-running occasioned by the carbons of the arc coming too near together, for even a relay to put in a substitutional resistance would hardly work to prevent this. Diagrams of the various connections are given in the article.

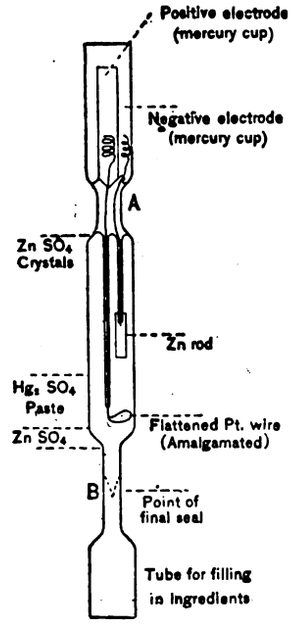
CONTEMPORARY ELECTRICAL SCIENCE.

[Compiled by E. E. Fournier d'Albe.]

Uranium Radiation.—Two different kinds of Becquerel rays have up to the present been discovered. One kind has practically all the characteristics of cathode rays, and is deflected by both magnetic and electric forces. The other kind is not deflected by either, and shows various degrees of absorption by metals and other opaque substances. Radium emits both kinds of rays. Polonium only emits the second kind, while Debierne's "actinium" only emits cathode rays. H. Becquerel has done some work in order to determine the exact nature of the rays emitted by uranium, the first substance which was found to emit the rays named after him. The difficulty of operating with uranium lies in the feebleness of its radiation. He found, however, that the rays emitted were deflected to about the same extent as the most penetrating radium rays. That might be explained by the supposition that uranium contains an admixture of radium, and that the true uranium rays are feebler. But the author believes that these deflected rays are due to actinium. They can be removed by treating the uranium chloride with barium chloride. Radio-active barium sulphate is produced, and a purified uranium salt remains. Further purification makes no difference, and hence it is probable that uranium has a definite though feeble radiation of its own. [H. Becquerel, *Comptes Rendus*, June 11, 1900].

Hermetically-sealed Clark Cell.—H. T. Barnes gives particulars of the construction of Clark cells completely closed by glass fusion. The arrangement of the cell is shown in the diagram. The positive electrode is a platinum wire flattened



at one end and amalgamated. The wire is enclosed in a glass capillary drawn from a small glass tube, shown in the figure, as the positive mercury cup. The negative electrode is a small zinc rod cast round a platinum wire and its enclosing glass capillary. This wire passes through the constriction A and ends in the outer or negative mercury cup. As soon as the ingredients of the cell have been filled in through the open end, the final sealing of the cell is accomplished by quickly fusing the glass in the narrow neck B. For making connections with terminals a small quantity of mercury is put into the cups. It can be at once removed when the cells have to be packed or sent away. The cell may be kept in any position. It may be immersed in a thermostat up to the neck A, and it still remains insulated thermally from the outside electrodes by the thick glass of the neck. The arrangement of the inner electrodes prevents the creeping of the amalgam, which almost invariably splits the tube at the point where the negative terminal is fused through the glass. [H. T. Barnes, *Phys. Review*, May-June, 1900.]

Viscosity of Liquids in an Electric Field.—It is still a debatable question whether the viscosity of a liquid is altered by immersing it in an electrostatic field. Fifteen years ago, König came to a negative conclusion. Duff in 1896 and Quincke in 1897 found that a number of alcohols, oils, and ethers show an increase of viscosity in an electric field. In addition, Duff observed a decrease in the case of heavy paraffin oil. The methods used by both the authors have been objected to, and G. Pacher and L. Finazzi have therefore made further experiments. They allowed various liquids to trickle through a set of tubes each of which formed a liquid condenser, and contained a central tube filled with mercury. Any change of viscosity consequent upon charging the condensers would have been indicated by a difference in the rate of fall of the meniscus. No change, however, was observed, although the liquids included such various kinds as water, alcohol, ether, benzol, turpentine, and carbon bisulphide. If there was a difference, it must have been less than 0·01 per cent., and the results obtained therefore make out a strong case for a negative reply to the question stated.

[Pacher and Finazzi, *Nuovo Cimento*, April, 1900.]

Heat Due to Cathode Rays.—The heating up of the cathode, which invariably accompanies the formation of cathode rays, has some practical bearings apart from the ordinary vacuum tube phenomena. It is well known that in continuous-current incandescent lamps the negative end of the carbon disintegrates more rapidly than the positive end, and in favourable circumstances a violet aureole can be seen to play around the cathode end. The latter rapidly loses its gloss, and probably contributes most material to the formation of the age-coating. P. Villard points out that the filament of a lamp can be made incandescent by means of an induction coil, if it is made into a cathode, and another filament is mounted as an anode in the same tube. The phenomenon may be produced at pressures up to one atmosphere by using metallic instead of carbon filaments. Care must be taken to have the current impulses in one direction only, and not to have the period of interruption the same as the period of elastic vibration of the filament. The difference of potential required to produce incandescence by the cathode effect is much higher than that required by the Joule effect, but the current required is much less. Tesla's incandescence phenomena are probably due to cathode heat.

[P. Villard, *Comptes Rendus*, June 11, 1900.]

Magnetic Field due to a Moving Electric Charge.—According to Maxwell's theory, a body carrying an electrostatic charge of surface density σ, moving with a velocity v, should produce a magnetic field equivalent to that of a conduction current. The intensity of the equivalent conduction current is given by the formula

$$di = ds\sigma \frac{v}{V}$$

where ds is the surface element of the charged body, and V the ratio of the electromagnetic to the electrostatic unit of quantity. In 1876 and in 1889, Rowland made some experiments which seemed to confirm this prediction. Such experiments, however, are very difficult to perform satisfactorily, as the forces to be measured are excessively small. Lippmann pointed out, as a logical consequence of Maxwell's view, that electrified bodies would be moved by every change in the intensity of the surrounding magnetic field, and he failed to discover any such motion. V. Crémien has accordingly conducted some new experiments on the same subject. Instead of watching the effect of a moving charge on a suspended magnetic needle, he made a charged disc rotate in the centre of a large coil and in the same plane. The charging of the disc would be equivalent to the establishment of a circular current, and should therefore produce an induced current in the coil. But no such effect was produced, whether the disc was left bare, or lacquered, or cut into three independent and insulated sections. It remains to square this fact with Maxwell's theory.

[V. Crémien, *Comptes Rendus*, June 5, 1900.]

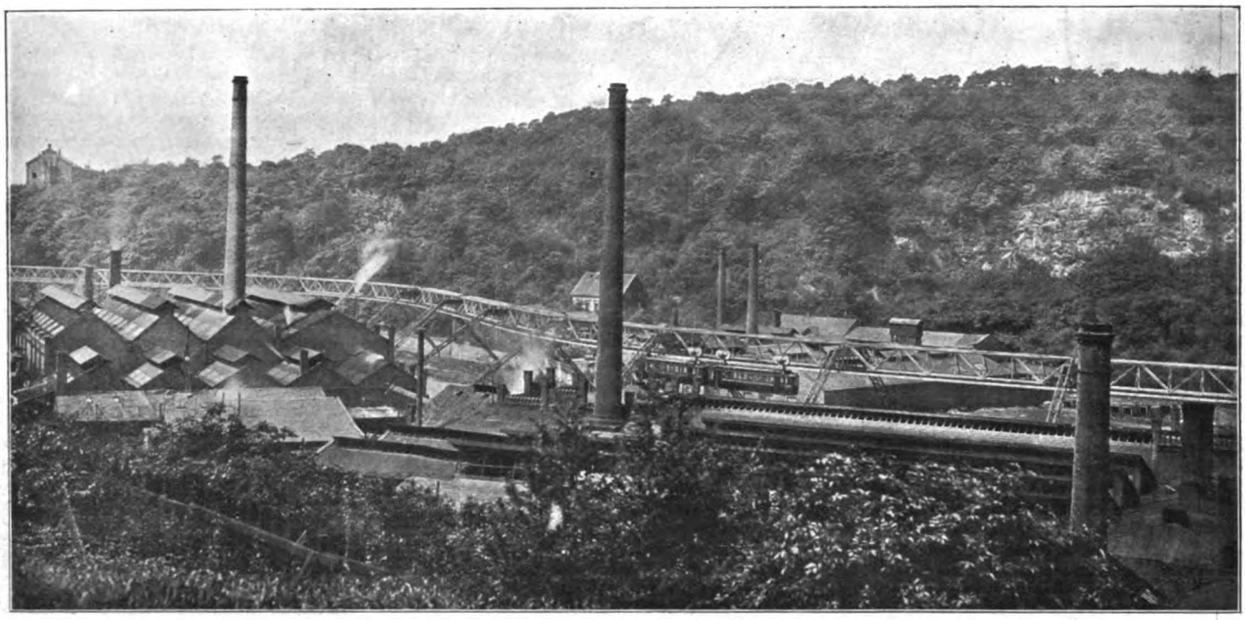
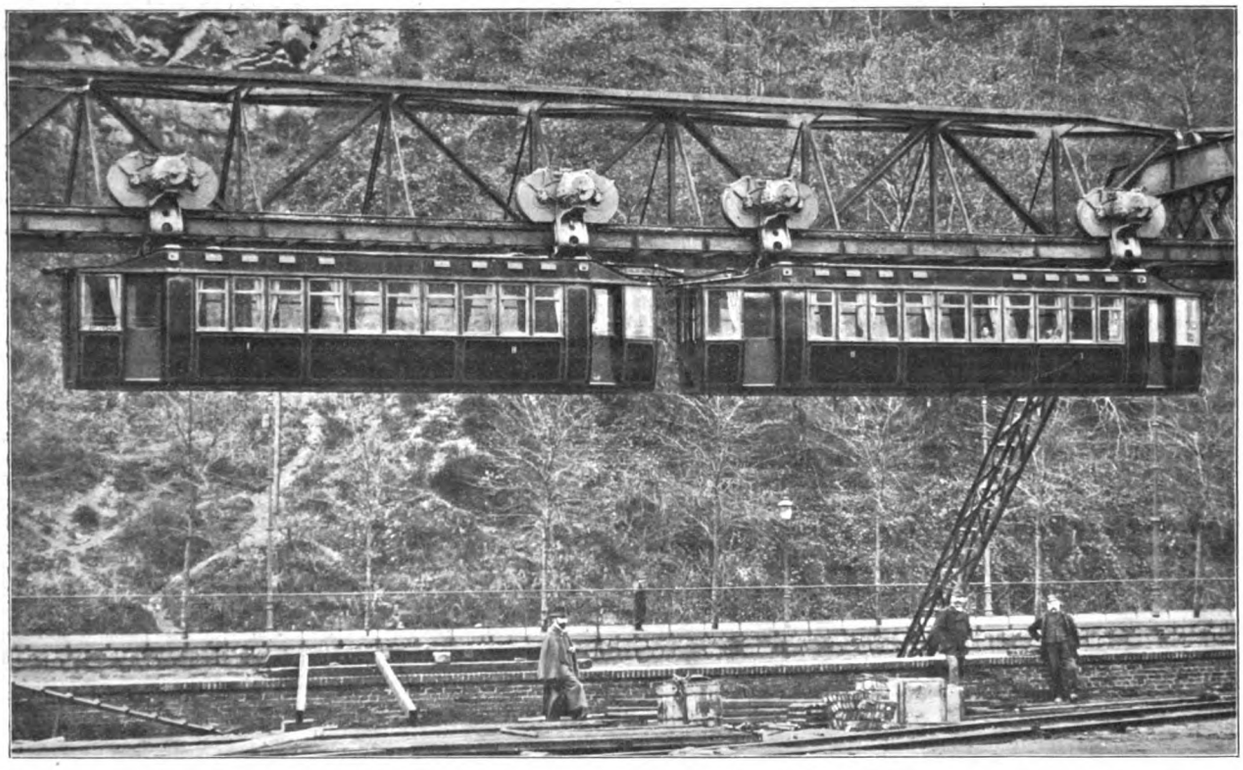
THE BARMEN-ELBERFELD MONO-RAIL OVERHEAD RAILWAY.

In a recent number of *The Electrician* (Vol. XLIV., p. 885), we announced the completion of a novel form of overhead electric railway between Barmen and Elberfeld, in Germany. Electric Co. we are enabled to present our readers with some illustrations of the German line, which has been constructed and equipped by the Continentale Gesellschaft für Elektrische



General View of the Barmen-Elberfeld Railway.

In view of the attempt to introduce a mono-rail system for an express railway between Liverpool and Manchester, the successful completion of the Barmen Elberfeld line possesses special interest at the present moment. Although the Liver- Untermehmungen, of Nurnberg. These illustrations clearly show the general construction of the railway, and doubtless will convey to our readers a correct sense of the combined lightness and safety which this type of railway construction



Barmen-Elberfeld Mono-rail Railway Train.

pool-Manchester scheme was rejected by the Parliamentary Committee, it doubtless will not be long before an attempt to introduce the mono-rail system between these two cities is again made. Through the courtesy of the British Schuckert introduces. The Barmen line cannot be called a high-speed line, as the normal speed is under 30 miles an hour. Moreover, many of the curves are too sharp to allow of a high speed. The railway abundantly demonstrates, however, the

Digitized by Google

feasibility of running a suburban or inter-urban service of light electric trains on the mono-rail system. The particular mono-rail system which has been adopted for the Barmen-Elberfeld line is that invented by, and associated with the

CURVE CONSTRUCTION OVER THE RIVER WUPPER.

name of, Eugen Langen. Unlike the Lartigue system, selected for the proposed Manchester-Liverpool line, the trains on the Langen system are suspended beneath the track rails, while the motors are carried on bicycle bogies above these

VIEW OF STREET CONSTRUCTION.

rails in the manner shown in the illustrations. There are four motors on each train, the train consisting of two coaches; each motor running at 500 volts and capable of developing 86 H.P. The carrying capacity of the train is 50 passengers. The motors are constructed for very rapid acceleration necessitated by the large number of intermediate railway stations, there being altogether 18 stations on a total length of only about 8¾ miles of line. The acceleration admits of full speed being attained in from 10sec. to 15sec. The trains are provided with four kinds of brakes, viz., the Westinghouse air brake, which is also controlled by a hand brake worked either by the conductor or driver, an electric brake and an emergency electric brake.

Several different forms of overhead construction have been adopted as the line passes for a considerable part of its length over the River Wupper, and also for some part over the streets of Barmen. Our illustrations show the manner of adapting the construction to these different conditions.

THE INTERNATIONAL CATALOGUE OF SCIENTIFIC LITERATURE.*

In view of the proceedings at the recent third International Conference, there can be little doubt that the ultimate execution of this important enterprise is now assured. Prior to the meeting some of us, perhaps, vaguely feared that the foreign delegates would come prepared to suggest all sorts of difficulties, if not to announce the unwillingness of the countries they represented to take any part in the work; but nothing of the kind occurred. All came bent on securing success; not a word was uttered in depreciation of any of the proposals brought under consideration; and all present may be said to have taken an enthusiastic interest in carrying the proceedings to a satisfactory issue. Everyone was of opinion that if a fair beginning can once be made—the importance of the work is so great, it will be of such use to scientific workers at large—that it will rapidly grow in favour, and soon secure that wide support which is not yet given to it, simply because its character and value are but imperfectly understood. Therefore, all were anxious that a beginning should be made.

It has been estimated that if 300 sets or the equivalent are sold the expenses of publication will be fully met. As the purchase of more than half this number was guaranteed by France, Germany, Italy, Norway, Switzerland and the United Kingdom, the conference came

* From *Nature*.

Digitized by Google

to the conclusion that the number likely to be taken by other countries would be such that the subscriptions necessary to cover the cost of the catalogue would be obtained. The resolution arrived at after this opinion had been formed, "That the catalogue include both an author's and a subject index, according to the schemes of the Provisional International Committee," must, in fact, be read as a resolution to establish the catalogue.

Of the countries represented at the various conferences, excepting Belgium, not one has expressed any unwillingness eventually to co-operate in the work. Unfortunately, neither the United States nor Russia was officially represented on the present occasion. The attempts that have been made to induce the Government in the United States to directly subsidise the catalogue have not been successful: but that the United States will contribute its fair share, both of material and of pecuniary support, cannot be doubted. There, as here, private or corporate enterprise must undertake much that is done under Government auspices in Europe. As to Russia, the organisation of scientific workers there has been so little developed that it is very difficult to secure their attention, and probably our Russian colleagues are as yet but very imperfectly aware of what is proposed. The importance of Russian scientific work is so great, however, that it stands to reason that it must be fully considered; and it may be supposed that Russia will join when she becomes acquainted with what is proposed and what is required of her.

A provisional international committee has been appointed, which will take the steps now necessary to secure the adhesion and co-operation of countries not yet pledged to support the scheme. Originally it was proposed to issue a card as well as a book-catalogue, but on account of the great additional expense this would involve, and as the Americans in particular had not expressed themselves in favour of a card issue, it is resolved to publish the catalogue, for the present, only in the form of annual volumes.

From the outset great stress has been laid on the preparation of subject indexes, which go behind the titles of Papers, and give fairly full information as to the nature of their contents. Both at the first and the second International Conference this view met with the fullest approval. Meanwhile, the action of the German Government has made it necessary to somewhat modify the original plan. In Germany a regional bureau will be established, supported by a Government subvention, and it is intended that the whole of the German scientific literature shall be catalogued in this office; no assistance will be asked from authors or editors or corporate bodies. In such an office it will for the present be impossible to go behind titles; consequently, only the titles of German Papers will be quoted in the catalogue. In the first instance, some other countries may prefer to adopt this course on the ground of economy. But in this country, at least, the attempt will be made to deal fully with the literature, and the co-operation of authors and editors will be specially invited. An author may not always be best able to judge which are the most important points in his Paper to be noted in an index, but the experience gained in the Royal Society during several years past has shown that authors furnish most valuable information, and that their suggestions are easily reduced into shape. A full code of instructions for the use of the regional bureaux is now being prepared under the auspices of the Provisional International committee.

The catalogue is to be published annually in 17 distinct volumes. The collection of material is to commence from Jan. 1, 1901. As it will be impossible to print and issue so many volumes at once, it is proposed to publish them in sets of four or five at quarterly intervals. During the first year, parts covering shorter periods will be prepared, so as to make the subsequent regular issue possible of volumes in which the literature published during a previous period of 12 months is catalogued. Valuable opportunity will thus be given from the outset of gaining experience both in the preparation and use of the catalogue. That many difficulties will be encountered in carrying the work out cannot be doubted; but if scientific workers generally will but reflect on the inestimable value of accurate classified subject indexes, they cannot but see that it will be to their great advantage to do all in their power to further the enterprise. If the attempt fail, it will only be because those on whose behalf it is undertaken are blind to their own interests. H. E. A.

Revival of Telpherage.—The Consolidated Telpherage Co., of New York, has considerably developed and perfected on modern lines the system of telpherage originated by Prof. Fleeming Jenkin some years ago. The American telpher, however, differs considerably in detail from that of Prof. Jenkin. It consists of a truck or bucket supported from a motor vehicle riding on a single cable or wire. A short distance over this cable there is an ordinary trolley wire, current being collected from this by a small trolley wheel similar to that used on tramways, but much smaller. The system is designed for use both overhead and in tunnels.

THE NEW PHYSICAL LABORATORY AT OWENS COLLEGE.*

BY PROF. ARTHUR SCHUSTER.

The physical laboratory which is to be opened to-day* by Lord Rayleigh will form an important addition to the buildings of Owens College. The general public has often a little difficulty in understanding the nature of the work done in a physical laboratory, owing to the association of the word "physics" with quite different matters, such as "physical exercise" or "physic." To trace the origin of the word in its various meanings would be an interesting undertaking. But at present it will be sufficient to recall the fact that Aristotle's book on "Physics" dealt chiefly with the idea of movement, and in that sense "physics" was used a good deal in the Middle Ages. But in a work entitled "Physica," by Melchior Verdries, the third edition of which was published in 1735, a much wider meaning was given to the word and "physics" was defined as including the following: (1) Cosmology (2) stoicheiology, or the doctrine of the elements, (3) uranology, (4) geology, (5) meteorology, (6) mineralogy, (7) phytology (botany), (8) zoology, and (9) anthropology. This pretty well covers the range of human knowledge so far as the material universe is concerned, and if the word was generally used in so wide a sense a man who knew physics must have been a wise man. Probably, therefore, originally "physician," like the word "doctor," only indicated a learned man, and the only learning appreciated by the public being that capable of dealing with the pains of the flesh, it is obvious how both "doctor" and "physician" came to have their special meaning. Without wishing to trace the further varieties in the meaning of "physics" as a science which occur in different writings and in different countries, it is sufficient to say that at present by general consent the word indicates that branch of human knowledge which deals more especially with sound, light, heat, magnetism, and electricity, and the general constitution of the material world. A laboratory in which all these branches of science are studied experimentally must therefore be provided with a considerable outfit of appliances of the most varied character.

Attention may be drawn to a few of these. The properties of bodies have to be studied at various temperatures, and it is important to be able to pass quickly from the temperature of freezing to that of boiling water. This can be done partly with the help of ice on one side and of steam on the other. Ice is easily obtained, and, to save time and trouble, steam in our new laboratory will be available in most of the rooms. For this purpose special pipes are laid from a small boiler into the different rooms. If a wider range of temperature is required, we have recourse to the electric furnace or the cooling action of liquid air. In the electric furnace the heat is supplied by electric currents, and the temperature may be raised to over 6,000°F. But a very considerable power is absorbed in the process. Moissan, at Paris, uses as much as 50 H.P. in some of his work, but half that power is sufficient for most purposes, and will be available by means of a gas engine presented by Mr. W. J. Crossley and dynamo machinery constructed by Messrs. Mather & Platt and the Electric Construction Corporation. Air can be liquefied and a temperature of 300deg. below zero reached by means of a pump which compresses the air to 200 atmospheres. This air is then forced through very narrow openings, when a cooling of a few degrees takes place. The air thus cooled serves to lower the temperature of the compressed air before it passes the opening, which is cooled down another step, and gradually the air becomes colder and colder until it falls down in the form of rain. The liquid air is collected, and can be drained off like water. The plant, the most expensive portion of which consists of a Whitehead compressing pump absorbing 4 H.P., has been presented to the laboratory by Sir Henry E. Roscoe. A high pressure of 200 atmospheres will of course be useful for many other purposes, but, independently of this, the laboratory is supplied with air compressed to four atmospheres, a pressure of that amount or less being often required for different objects. The pump used for this purpose is attached to a small steam engine placed in the boiler-house, and iron pipes diverge from here to the different rooms of the laboratory.

The knowledge of accurate time intervals, which is important in many investigations, renders the possession of accurate clocks, expensive as they are, absolutely imperative. The clock to be placed in the basement of our new laboratory will probably be the most perfect clock in the country. It is made by Dr. Riefler, of Munich, and has in its original form been tested in many observatories, and found to keep more perfect time than the older types of clock. But a further improvement has been recently introduced, for it is found that a very slight disturbance in the rate of the clock is due to the difference in the retardation due to air resistance which takes place according to the height of the barometer. A pendulum clock which keeps accurate time when the barometer is exceptionally high would gain about a second a week when the barometric

pressure is exceptionally low. It is a sign of the perfection of Dr. Riefler's clocks that he has found it worth while to correct and compensate so trifling an error. So valuable a timepiece must of course be kept locked up in a room, and will not be generally accessible, but time is supplied to the different parts of the laboratory by electric transmission from a second clock. The lecture rooms and the larger rooms of the laboratory will all contain dials showing time correct to within a few seconds.

Special attention has been paid to the optical outfit of the laboratory. One of its features will be a room on the top floor which contains the so-called Rowland's diffraction grating. The object of the grating is to split up light into its various components in the same way as is done by a prism, the whole apparatus acting like a spectroscope. These gratings are made of speculum metal, on a plate of which a space of 6in. is covered by lines ruled very close together with a diamond point, the total number of lines being over 100,000. The ruling of these lines, which must be accurately spaced, is extremely difficult, although done by a ruling machine. An idea of the difficulty experienced may be obtained from the fact that it occasionally takes three or four years before a satisfactory grating is manufactured. The one supplied to the college has been certified by Prof. Rowland as exceptionally good, and carries an inscription stating that it has been specially selected for the professor of physics at Owens College. The mounting of the granting is peculiar, and takes up a good deal of space. Two iron beams over 20ft. long, stretching across the room, are placed exactly at right angles to each other. Each beam carries two rails, and small carriages can roll along these rails. One of these carriages carries the grating, while the other carries the photographic camera or the eyepiece which serves for observation of the spectrum. The two carriages are connected by an iron girder over 21ft. long, and this girder has to be specially steady so as not to be subject to vibration. This construction of the girders and their supports has been specially designed by Sir Howard Grubb, and it is hoped the mounting will be a considerable improvement on that used in the three or four places where these gratings are at present to be found. The room in which this apparatus is situated has of course to be kept dark, but there must be some means of obtaining a beam of sunlight or a beam of an electric arc when required. For this purpose a balcony has been built. This runs along the west side of the building, and sunlight may be thrown by means of inclined mirrors through openings in the wall.

The photographic laboratory is in the basement. The observatory, placed on the top of the building, contains the 10in. telescope presented by Sir Thomas S. Bazley. There was some difficulty in providing a sufficiently steady foundation for the telescope, but it is hoped that this has been successfully overcome. The electro-technical laboratory, built and equipped in memory of Dr. John Hopkinson, has been provided, as far as the means at the disposal of the college have allowed, with the most modern form of machinery. Considerable space has been assigned to an electro-chemical laboratory, and as a special lecturer has been appointed in that subject it is hoped that Owens College will take a leading part in its development.

As regards the general arrangements of the laboratory, it may be said that the walls are lined almost entirely with glazed bricks, which are easily kept clean. The question of ventilation has received careful consideration. For a number of reasons the so-called plenum system was found unsuitable for a physical laboratory, and some process of natural ventilation was adopted. Air is admitted through openings in the wall, and passes over a surface of oil, which frees it from dust. This is an invention of Mr. Kenneth Teale. The arrangements for heating, which is done by low-pressure steam, and for drawing off the vitiated air have been devised by Mr. E. Hatton. An electric lift connects the different floors, and will serve principally to convey delicate apparatus from one part of the building to another. There will be a small but well-equipped workshop in which instruments can be repaired or even made. The large lecture-room holds, under ordinary circumstances, 210 students. It has a skylight as well as windows looking to the east, and rapidly moving shutters allow the room to be quickly darkened. The small lecture-room serves for advanced lectures, and rooms are provided for storing the ordinary apparatus and also some historical instruments, as, for instance, Joule's valuable apparatus, some of which have been presented to the college. In a modern laboratory it is essential that the electric current should be available in every room for experimental purposes. This current is supplied from 60 storage cells, which are connected through a large switchboard over 15ft. long. Thirty circuits diverge from this switchboard into the various rooms, the circuits consisting of aluminium or copper wire, stretched principally under the ceiling of each room and passing through specially perforated bricks in the walls. Uncovered wires have been chosen for the purpose, as the expense is reduced, and much stronger currents can be sent through the same thickness of wire; there is also gain in the neatness of appearance. The research-rooms are placed principally in the basement and on the ground floor of the building, where the greatest steadiness and freedom from disturbance can be obtained, and it is hoped that the unusual facilities which in future will be given at Owens College for original research in physics will attract many students. There is also every reason to hope that the John Hopkinson electro-technical laboratory, with its adjunct, the electro-chemical laboratory, will soon make itself felt in the education of electrical engineers, who will be trained to carry out the highest technical work they may be called upon to perform.

THE LIGHTING OF SMALL TOWNS.*

BY G. M. HARRIS,
(Electrical Engineer, Bray, Ireland.)

The lighting of small towns is a problem requiring very careful consideration, not by reason of any engineering difficulties, but by reason of the difficulty of making such an undertaking pay. On account of the profits being necessarily small, the lighting of small towns will continue to receive little attention from private companies, except they be very plucky ones. The matter will, therefore, be left for the consideration of the local authority, who will be content, or at all events should be, if at a reasonable cost they are enabled to carry out the public lighting of the town, and at the same time place a supply of electricity at the disposal of its inhabitants. The measure of the success of such an undertaking should then be judged, not by actual return made in the shape of profit shown, but upon truly municipal lines, *i.e.*, by the efficiency and cost of the public lighting and the rate at which a supply of electricity is obtainable for private use. Small towns mean small consumers and usually a scattered area. The distributing charges will be heavy, so that if there is to be any hope of success the generating charges must be light, which means that the site for a generating station must have very special natural advantages, such as good water power or facilities for cheap fuel, or a combination of the two. Where there are no such advantages there appears to be no alternative but to wait for the great power companies to pick up such small areas as may be within their reach or upon the direct line of route of their mains to larger ones. Assuming that the conditions are favourable for generating or obtaining a supply at a low cost—at the commencement, the public lighting should be provided for and taken over, and provision only made for private consumers where such are certain to come on in a reasonable time. The policy of laying the mains for private use well in advance of the demand, though justified in wealthy areas, would not be so in small towns where the conditions are different. The prospect of profit in supplying small and scattered consumers being very small, there is no room for speculation, and it is of the utmost importance that the capital expenditure be kept as low as possible, and that no capital should be unproductive. It therefore follows that the system of distribution should possess the maximum of flexibility at the minimum of cost. Now that distribution up to 200 volts has been successfully established, there are, of course, many towns where direct current would be feasible and no doubt preferable, but in the majority of cases high pressure alternating current with transformers in street pits and occasionally in houses would be better; where the area comprises a number of private houses and mansions, standing in their own grounds and of necessity widely scattered but nevertheless desirable to reach, the alternating system is the only one commercially possible. This question, however, will, of course, be governed by the circumstances in any particular district, but the question of the actual cost of mains will always remain—a serious item telling against economical distribution on a small scale.

It is therefore the object of this Paper to deal with the matter of cheap mains and main laying, that being, I consider, the most important point—the one which lies nearest towards a solution of the problem under consideration. I therefore propose to bring to the notice of this Association two cheap and effective methods of main laying, of which I have had experience at Bray. First, as to the mains in operation at Bray—there have been over 6 miles of high and 27 miles of low tension laid direct in the ground since 1892, and during that time we have never had a fault on the main line of cables themselves, except where mechanical injury had caused it, and this has very seldom happened. Any trouble we have had has been due to defects in the filling material of the jointing boxes, now overcome, so that this system of laying may claim to have been well tried. In fact, I think the Bray mains are the oldest paper-insulated cables in the Kingdom, other than those from Deptford. The cables are concentric lead-covered and unarmoured—they are taped, but this is, in my opinion, a disadvantage. In laying, the bottom of the trench was covered with about 3in. of puddle clay, well wrought, the cables laid in and covered with another 3in. of puddle clay, evenly put on, and a 7in. by 1in. board placed on top, the trench being then filled. Latterly, the timber used for mechanical protection has been larch—being simply the small larch trees, 7in. thick in the butt, sawn in half. This timber stands well in the ground, requiring no special treatment to preserve it, is cheaper than deal

boards, and more effective, being thicker. The effect of the puddle clay, impervious to moisture, is to protect the lead covering from any contact with acids or salts in the soil which would attack it, and it has proved so effective that when the cable is now, after eight years, exposed, the lead is absolutely unattacked. The braiding of the cables has rotted, proving to have been an unnecessary expense; it might prove a source of danger if it allowed the passage of water charged with matter which would attack lead, the life of a lead-covered cable being practically the life of the lead. As to the jointing, no clips are used, the inners are married and soldered in the usual way, the outer wires are drawn to one side and soldered together forming a loop, all soldering being done well clear of the cable insulation. The joint is contained in a cast-iron joint box divided longitudinally on the line of two bottle necks for entrance and exit of cable and having on the top side a large hole for filling (not less than 1in.) and a smaller hole as air vent, closed by screwed plugs. The cables are served with spun-yarn up to the diameter of the bottle necks and no other packing of the glands is found necessary. The joints having been made and the box screwed up, molten pitch is poured in; the outer side of the bottle necks, beyond the spun-yarn serving, is also filled in with pitch, hollows being formed in the clay for the purpose, and here fine clay mixed with the pitch forms a cement which effectually seals up the bottle necks and protects the cable from injury where they enter and leave the box. Such a joint is cheaply made and fulfils every requirement. It demands only care, and requires absolutely no special skill, a very important matter in a small town. This, and the fact that it is both electrically and mechanically sound, gives a joint so made advantages which no form of joint made with clips, which the writer has seen, can claim. Where any transformer pits lie on the route all cables are brought into the pits and are joined there, inners and outers, with loops of rubber-covered single cables; disconnection of any length of cable for tracing a fault is done by snipping these loops, and this works well under our conditions. Of course in a large scheme where the expense was no object disconnecting boxes would be preferable, but when used they should certainly be placed in pillars above ground and so above the reach of flooding, and not in water tight boxes under ground.

As far as the writer is aware, the insulation resistance of mains in operation is not usually easily obtainable, but he has reason to believe that the above are more than ordinarily low. This, however, in no way reflects on the cables; it is partly due to the fact that originally oil was used in the joint boxes, but was soon abandoned, not, however, before the cable ends had suffered, due to water mixing with the oil—the repairing of these ends accounts for the large number of joints. The main cause of the low insulation is due to the large number of joint boxes, which still contain a mixture of tar and pitch (the tar having been added as a precaution against cracking of the pitch). This mixture is inferior in every way to the pitch alone, which is now always used. The fact that the resistance from the inner to the outer is in the majority of cases greater than that to the earth is no doubt accounted for at the joints, where the resistance of the pitch has been weakened in the manner indicated, and the surface of the outer is small in comparison to the surrounding box. Their condition, however, causes no anxiety at Bray, as the tests are practically identical with those taken in 1893; the cables have been perfectly steady all along, and have lived to see much of the more elaborate and costly drawn-in system placed on the scrap heap. The cost of laying the cable described was under 1s. per yard of trench, made up as follows: Opening and filling trench 20in. deep, including mixing of puddle clay, from 3d. to 6d. per yard. Puddle clay at 2s. 6d. per ton, sufficient for three cables, 3d. per yard. 7in. by 1in. board for mechanical protection, 2d. per yard.

The average cost of a joint being under 10s., as follows:—

	s.	d.
Joint box, complete	4	6
Pitch, solder, fire, &c., say	2	6
Labour	2	6
	9	6

Sufficient has been said perhaps to show that such a system of laying and jointing mains is cheap and reliable, in any case in which no danger from electrolytic action is feared—as where, for instance, a tram line passed through a town. In such a case the lead would need protection, and recourse to some solid system seems inevitable; but a small town cannot afford the luxury of lead-covered cables laid in this way, and the lead seems to me quite unnecessary, serving no purposes which would not be equally served by any cheap covering which would protect the insulation from damp up to the time of being laid, after which it requires no such protection. If the cables are concentric the outer insulation can be reduced to that thickness which, with the filling, suffices for the voltage carried; if the cables are not concentric then the covering of each may be reduced to that thickness which, with the filling, is good enough. The question is, how much the insulation, other than that of the filling compound, may be reduced? My impression is that, driven by consideration of cost, we shall see this extra insulation year by year reduced in amount, till, for low voltage, we come to the bare conductor laid on insulators in the solid filling, and for higher voltage, conductors laid on the same system with very slight extra insulation, relying mainly upon the filling compound. The inevitable result of this will be that we shall, for the conductors, use iron or other metal, or alloy, cheaper than copper, since the prohibitive cost of the increased insulation, due to bigger cross-section for the same conductivity for such metals, will not have to be faced. At Bray we tested some years ago 80 yards of bare copper mains laid on the solid system, and although roughly laid and badly insulated, the filling compound being a mixture of bitumen, tar and sawdust, this nevertheless stood 1,000 volts for twelve months, and 100 volts for two years afterwards, and was then only taken up on account of building extensions. From that experiment and subsequent experience I believe it is perfectly possible, even now, for voltage, say up to 500, covering all low tension distribution for light and traction, to use wires covered with, say, a few layers of paper and a light braiding varnished, and the whole laid in troughing filled in with plain pitch at 10s. per ton, which, for all sizes of copper above, say, 0·25in. sectional area, would be cheaper than any cable in the market. Whatever be the nature of the solid system, the compound for filling both joints and troughing should be ordinary pitch, which has the advantage that it can with ease be chipped out, and is cheap. In most small towns, for the public lighting of outlying country roads, overhead bare wiring might be employed, for doubtless the sanction of the Board of Trade for their use, at all events for the first years, might be obtained. On the whole, however, the regulation preventing the use of overhead wires does not press very hard upon small towns, where usually labour is cheap and the roads easily opened.

Returning to the general question, it may safely be said that where gas has been well established, the outlook for a private consumption of electricity will be in inverse proportion to the price charged for gas, for, where a high price prevails, the inhabitants will be found educated to the closest economy in its use, and it is surprising how far this can be carried.

BATTERIES FOR AUTOMOBILES.

Dr. Sieg, discussing the subject of portable batteries in No. 10 of the *Centralblatt für Accumulatoren und Elementenkunde*, says that there is still considerable divergence of opinion concerning their usefulness, and that the breakdowns which have occurred on the Berlin tram lines have given a fresh handle to those who oppose their employment. He does not concern himself with these breakdowns or with their causes, but passes on at once to the general consideration of the employment of batteries for the propulsion of ordinary road vehicles. In stationary batteries it is only the chemical processes involved in the storage of the current which act injuriously on the plates, and as there is no necessity to keep down the weight or size of the batteries, heavy electrodes may be employed, spaced far apart, and a good depth may be left below the bottom of the plates, so as to reduce the risk of damage from short circuits and buckling to a minimum. The work required of the battery is also known accurately beforehand, so that damage due to overstrain can

Digitized by Google

be avoided. But in the case of batteries propelling automobiles the conditions are very different. Weight and size have to be restricted as much as possible in order that the vehicle may not be too heavy, for weight not only increases the working cost of the vehicle, but also reduces its handiness. The amount of current used, and therefore the demand on the battery, varies with the conditions of working and the state of the roads. Wet roads, sandy soil, stones, &c., increase the demand enormously, so that not only the normal current, but also the normal capacity, may be far exceeded. The batteries are also constantly subjected to severe jolting, which seriously affects their life. Dr. Sieg then proceeds to the consideration of the properties which are required in an automobile battery, and as a preliminary lays down certain requirements which must be fulfilled.

The weight of the empty carriage ought to be from one-half to three-fourths of the weight to be carried by it according to the method of construction employed, and the speed to be attained. For the conveyance of passengers, two-thirds of the total weight may be allowed. This total weight is made up as follows: The motors, which for a passenger car for a speed of 15km. to 18km. per hour amount to one-tenth of the total weight of the occupied car (W), the battery (B), and the passenger weight which may be taken at 0·3 tons (four persons at 75 kg. each). It follows from this that

$$W = 0{\cdot}6 + 2B.$$

As carriages exceeding 2 tons in total weight cannot be safely steered at a higher speed than 15km. to 18km. per hour, it follows that the battery weight must not exceed 700 kg.

Taking the commercial efficiency of the motor as 70 per cent., and assuming a traction coefficient of 25, which is rather too low than too high on a good road, the consumption of energy by the carriage in 18 kilometre-hours, or 5 metre-seconds, works out to $1{,}750 \times W$ watts. Assuming that the carriage will require to run at least three hours on one charge, that is somewhat over 50km., which corresponds to the daily service of a taxameter cab, the battery will require a capacity of 5,250 watt-hours, *i.e.*, in order that the working generally may be possible, the battery must yield at least 10·5 watt-hours per kilogramme weight, or be capable of yielding 5·5 ampere-hours at a 3-hour discharge at a potential of 1·9 volts.

As it will seldom happen that a carriage will be called on to give its whole yield without some stoppage, it will as a rule be sufficient when the battery gives 8 ampere-hours per kilogramme with a 5-hour to 6-hour discharge. Or when the battery has a higher capacity per kilogramme weight, a smaller battery weight than 700 kg. will suffice; but if the battery has a lower capacity, it will not maintain the daily work of 50km.

For stationary batteries the capacity per kilogramme varies between 3 ampere-hours to 5 ampere-hours, so it is evident that to fulfil the conditions required by an automobile the battery must have only about half the weight of a stationary battery, or else have double the ordinary capacity. Weight may be reduced by making the cells themselves lighter, which can be done by employing vulcanite in their construction instead of glass, &c. The weight of the acid may also be diminished by reducing the distance between the plates, and the space allotted to them, but since the production of an ampere-hour always requires the consumption of a definite quantity of pure sulphuric acid, the diminution of the quantity of the electrolyte must be compensated for by an increase in its density, which at once has the injurious effect of raising the working potential of the cell. The reduction of the distance between the plates is further attended with the risk of short circuit from a very small amount of buckling, which is best obviated by the employment of perforated and corrugated distance plates of vulcanite, such as those manufactured by the Hagen Accumulator Works at Cologne. This construction is also employed by other leading manufacturers of automobile cells, such as the Société Fulmen of Paris, who adopted it after making trial of other methods. They found that flat separators spaced by rods of insulating material, gave unsatisfactory results because the circulation of the electrolyte was interferred with, as also was the descent to the bottom of the cell of the material dislodged from the surface of the plates. All gelatinous electrolytes have been failures, and all attempts to absorb the fluid electrolyte by dry fillings have had a similar fate, since a rapid circulation of the electrolyte through them is impossible. With a quick discharge they have a very high internal resistance, and they lower the capacity of the cell, while the gas bubbles soon form little hollow spaces and channels in the material in which the active material dislodged from the plates collects, and this occasions short circuits. The cost of these corrugated vulcanite separators is certainly very high, and therefore any cheaper method for satisfactorily attaining the same end would be welcomed.

But a decrease in the weight of the acid and of the boxes is not sufficient alone to raise the specific yield of automobile cells to about double that which is obtained from stationary cells, for the weight of the electrodes in the latter is about 50 per cent. to 60 per cent. of that of the total weight of the cell. Thus a considerable reduction is also required in the weight of the cells themselves, which can only be effected at the expense of their durability. The same durability, therefore, must not be expected from automobile cells as is required from those which are stationary, especially as the diminution in weight entails thinner plates, from which more chemical activity is expected, and greater current-carrying capacity, while mechanically they are subjected to the strains involved by perpetual jolting.

Of the three types of accumulator at present in use, *i.e.*, the large surface plates, the grid plates, and the block, the second is alone suitable for automobile batteries, because with the first-named the requisite yield of 8 ampere-hours per kilogramme cannot be obtained, and in the block plates the distribution of the current is not uniform, so that whole blocks lose contact with the supporting frames and drop out. The requisite specific yield combined with a reasonable durability can be obtained from the grid type if care is taken in the filling in of the plates that there is no break in the continuity, either of the lead salt, or between it and the supporting grid. Either a light double grid, riveted together, such as is employed in the Fulmen cells, or an E.P.S. grid, or any other of similar type, give good results if due care is bestowed on the filling in of the active material, and in placing the separators so that their corrugations press against the plates. As the result of experiments which have extended over two years at the Cologne works, Dr. Sieg has arrived at a method of construction which gives good results. For both positive and negative plates, hardened lead grids are employed having a thickness of 3mm. and whose mesh is 15mm. square. The plates are 130mm. wide, 200mm. high, and are mounted about 3mm. apart. The negatives stand on the bottom of the cell on legs 25mm. high, while the positives are suspended above them from vulcanite rods, so that they have room for downward expansion. By the employment of a specially prepared paste Dr. Sieg succeeded in fixing it securely in the grid, and in obtaining a yield of 10 ampere hours per kilogramme, with a 5-hour discharge. Between the plates are placed hard rubber separators half a millimetre thick, and the plates of like sign are united to each other by burning.

The first of these batteries was delivered to the Cologne Elektricitätsgesellschaft in March, 1899, and since that time has propelled a vehicle which has been used partly for business purposes and partly for the personal needs of the directors. The carriage weighs about 1,200kg., and has an 80km.-hour range. At the end of April, 1900, the cells, which had hitherto required no repairs, were cleaned, and it was found that the negative plates were still faultless, whilst the positive plates, although they had lost some material, were apparently capable of carrying on the work for some time longer. Before the battery was cleaned, the carriage had travelled with one charge over 60km. over somewhat soft roads, and the battery still had its initial capacity of about 120 ampere-hours, with a 5-hour discharge rate. These favourable results determined the Cologne Elektricitätsgesellschaft to give the Hagen works a commission for 19 batteries for employment on the cab service they were about to start in Cologne and Düsseldorf, and some of them have lately come into use.

Since the spring of 1899 experiments have also been conducted in the carriage building works of Heinrich Scheele in Cologne. He tried types of conveyance ranging from the lightest high speed vehicle to a heavy goods waggon capable of carrying 5 tons, and hitherto the batteries have given no cause for complaint. In the laboratories the batteries had yielded about 300 discharges at a 2-hour rate before a change of plates was necessary, and one may therefore reckon on at least 150 discharges being obtained without any repair being required when the batteries are employed for automobile traffic. Since those portions of the cell whose first cost is highest, *i.e.*, the vulcanite cases and the separators, suffer but little deterioration in use, it is quite sufficient to allow 30 per cent. of the initial cost of the batteries for their maintenance, and on these terms the makers are willing to undertake the maintenance of batteries in any towns in which they have agents.

Still more information concerning the durability of the batteries, and their behaviour under all conditions of work, should be gained as the result of the experiments being carried out in Berlin by the "Automobilkonkurrenz."

One circumstance may be mentioned which is of special interest to manufacturers, and that is that out of 40 batteries which the Hagen Company have already delivered, three did not maintain when in work the capacity which they had before being sent out from the factory, and on examination it was found that there was loss of contact between the active material and the grid in the negative plates occasioned by their having been exposed to frost before formation, and with this exception, the faulty plates differed in no respect in weight or construction from those which gave good results. Experimental batteries have been supplied to the tramway service in Bremerhaven which weigh about 2,000 kg, and will run cars weighing 11 tons for an uninterrupted journey of about 140 kilometres. The batteries have been in work since December, 1899, and have gone without stoppage through the heaviest snow without a change of plates being necessary. It remains to be seen how long these batteries will retain their efficiency, but if they only require to be renewed once in six months a satisfactory return will be obtained from them.

IMPROVEMENTS IN ELECTRIC SUPPLY PLANT.

The accompanying illustrations show some of the latest patterns of electric supply station and transformer plant and apparatus manufactured by Messrs. John Fowler & Co. (Leeds) (Ltd.). From the early days of electric lighting this firm has been steadily and

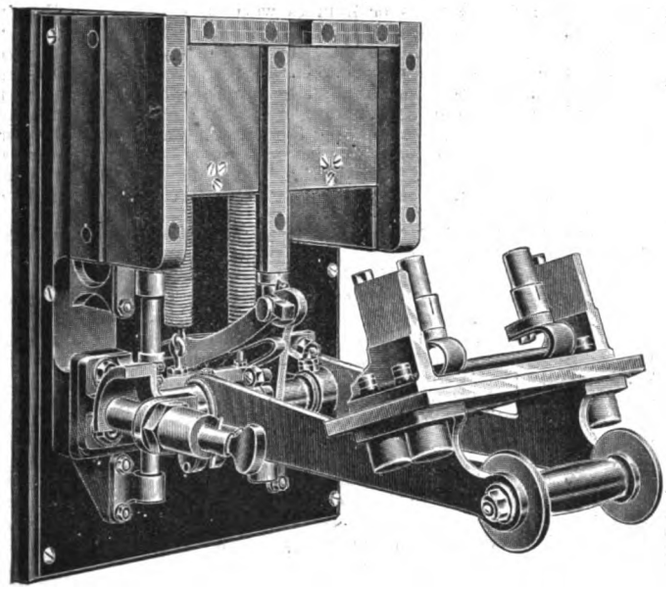

FIG. 1.—Switch open.

extensively connected with the development of the electric supply industry in this country as well as abroad, and it is one of the features of their manufactures that they are always being carefully brought up to range with the latest and best practice. Figs. 1 and 2 show a form of single-pole lever-type shutter switch, designed to

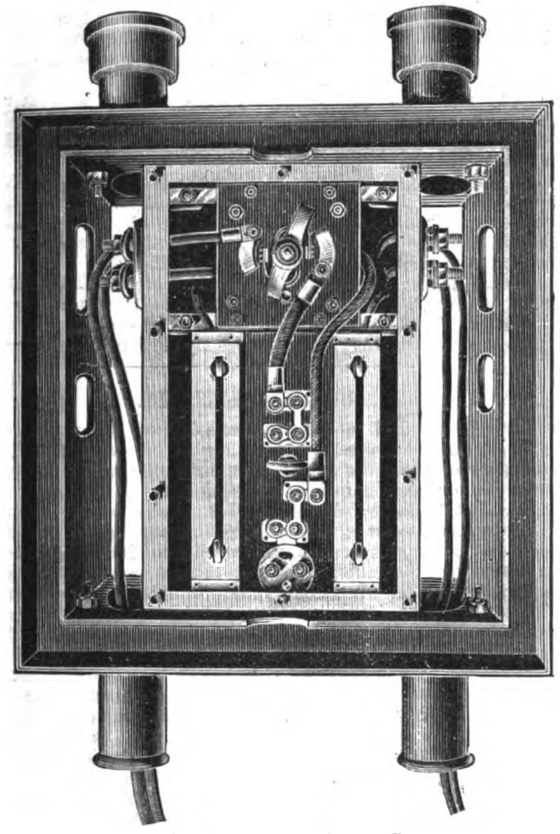

FIG. 3.—Plan of Transformer Box.

work in connection with large currents at high voltage. The illustrations show the switch both open and closed.

The base is of enamelled slate and carries two socket terminals which are mounted on heavy porcelain insulators, and are provided at the back with cable thimbles and nuts, and at the front are fitted with spring jaws and spring-pressed carbons. The base also carries brackets for the lever centres, the brackets for the shutter guide rods, and the guard slates. The lever portion of the switch consists of two brass levers held at their lower ends by a spindle, and at their upper ends by the handle and insulated bridge contact fitted with carbons. The shutters (one arranged for each contact) are mounted on

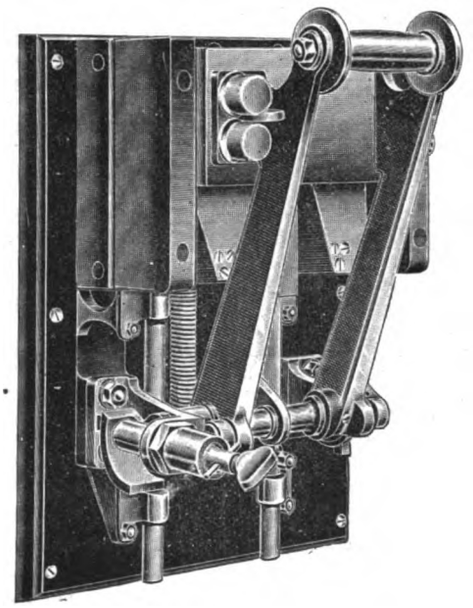

FIG. 2.—Switch closed.

brackets and guide rods; the rods are joined together by a cross-piece. Two springs hold the shutters firmly against the top guard. When the switch is in the "off" position jar or undue knocking is prevented by the rubber buffers. The shutters are further guarded by the guard slates, which are suitably grooved to effect this. The lever spindle is fitted with a spring-pressed lever which engages a cross-piece, and thus operates the shutter automatically.

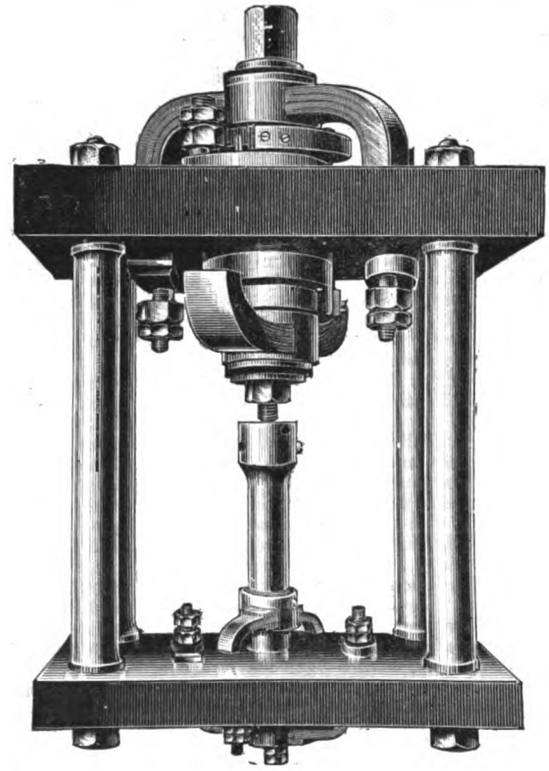

FIG. 4.—Underground Transformer Switch for High and Low-Pressure Circuits.

The switch is operated by pulling the handle fixed on the lever. During the travel the metal contacts will first break, leaving the carbons still pressing together until the holder of the spring-pressed carbon, which telescopes into a tube, comes to its limit of travel, when

Digitized by Google

the final break takes place between the two carbons, and immediately following this the shutter, which at that moment is released, flies up, and effectually breaks any arc that may be forming, and at the same time completely closes in the live parts of the switch; the contact plugs in the "off" position being entirely disconnected and therefore harmless. In closing the switch the spring-pressed lever engages with the shutter and causes the same to travel downward against the action of the shutter springs, and in this way uncovering the contact jaws to receive the plugs. Just before the lever has completed its travel, the spring-pressed lever is disengaged by its motion automatically, the shutter then moves upward to the underside of the plugs, and is thus ready to fly up when the switch is opened as already described.

The lever shutter switch is already in use on the main switchboards at Coventry, Newport, and Dublin, at a working pressure of 2,000 volts alternating. It is also in use at the Leeds Corporation tramways, working at a pressure of 500 volts to 600 volts, and a continuous current up to 1,500 amperes.

Fig. 3 shows a plan of the top of the underground transformer box made and recommended by this firm for use in distribution systems supplying power over a scattered area, or where the demand is not likely to be very heavy at any given point. The illustration shows the box with the cover and watertight lid removed. These boxes are made in two sizes, viz., a small size to receive transformers up to 9kw., and a larger size for transformers up to 22·5kw.

Fig. 4 is an elevation of an underground key switch for connecting or disconnecting transformers. This illustration explains itself. The switch breaks both high and low-pressure circuits simultaneously on both poles with a double break and when the transformers are working with the full load there is practically no sparking. The high-pressure contacts are mounted on ebonite and the low pressure on enamelled slate.

PARLIAMENTARY INTELLIGENCE.

MUNICIPAL TRADING.

The Joint Committee of Lords and Commons on Municipal Trading met again on Friday last, Viscount Peel presiding.

Mr. E. O. SMITH, town clerk of Birmingham, stated that his Corporation owned the gas, water, and electric supply undertakings of the city, besides the markets, the public baths, the tramways and the cemetery. At present the tramways were leased to companies, but as soon as the leases expired the Corporation intended to obtain Parliamentary powers to work them themselves. The Town Council had carried out large operations under the Artisans' and Labourers' Dwellings Acts, thus making very great sanitary as well as town improvements. They also owned a large amount of land in Wales in connection with their water undertaking, and the total capital invested in their eight undertakings was approximately £10,000,000. He regarded the carrying on of gas, water and electrical undertakings as municipal trading, and placed tramways in the same category if a corporation run them themselves. A profit of about £30,000 a year was made by Birmingham on the gas undertaking, and this went to the reduction of price and to the improvement rate. He did not believe that if the various undertakings had been worked by companies in competition with other companies, the consuming public would have secured the same advantages. It was, no doubt, a danger for a municipality to have in its employment a vast number of workpeople, but it was one that must be faced. He should like to see all corporation officials disfranchised, but he was afraid that was a policy which could not be carried out. In Birmingham no disadvantages had at present been experienced through having a large number of Corporation workmen who were also municipal voters.

On Tuesday (Lord Crewe presiding) the Committee resumed.

Sir T. HUGHES, alderman of the Liverpool Council and a member of the Liverpool Chamber of Commerce, expressed the opinion that a good many undertakings could be better carried on by corporations than by private individuals. Local authorities could obtain their capital at a lower rate of interest than private persons, and they paid no dividends, while his experience was that there were many men who devoted their lives to corporate undertakings instead of concerning themselves with private work. Liverpool Corporation managed the city tramways, the electric lighting, the water supply, the markets, public baths, workmen's dwellings, and open spaces. The Council consisted of 116 members, and was divided into 14 standing committees, no member of the Council being allowed to serve on more than one of these committees. The Liverpool tramway undertaking dated back to an experimental line in 1860, and came into the possession of the Corporation in 1897, being bought for £567,375, which he looked on as a most unreasonable sum. The Corporation were now reconstructing the tramways and adapting them to electric traction. Directly the Corporation came into possession they began to reconstruct the lines so as to adapt them to electric haulage. Already 63 miles of line had been constructed out of a total of 114 miles. In spite of the large sums they had had to spend, the Corporation had found it possible to reduce the fares by nearly one-half, to concede increased wages and better conditions to their employés, and to increase the speed of the cars. The result of the last-named improvement had been to improve the conditions under which the working classes lived. During the last years of the company's tenure (1896) the passengers carried on the trams numbered 36,704,379, while three years later the number increased to 63,771,450. The receipts increased from £278,446 in 1896 to £359,929 in 1899. As to the overhead electric railway, witness said that was under the special control of the Dock Board, and had no connection with the Corporation tramway system. The Liverpool tramways were on the overhead trolley system, and as the telegraph and telephone wires throughout the city had been laid underground, the appearance of the streets was little, or not at all, interfered with. They looked for great improvements when the whole electric system was completed. At present they had only done about one-half. It paid the Corporation better to take a penny fare for 1½ miles or 2 miles with electric traction than to charge 2d. for the same distance by horse traction. They had been able to pay interest upon the amount paid to the company for the undertaking, and also upon the cost of construction, besides providing the necessary sinking funds. He was of opinion that no municipality ought to look to assisting its rates out of undertakings of this kind until they were on a thoroughly sound basis, and Liverpool Corporation were debarred by their act from taking any portion of their profits for the relief of the general rates till the expiration of the year 1912. There ought not to be too much temptation to create undertakings in order to make profits for the relief of the rates.

The CHAIRMAN asked for some information as to the Corporation's electric undertaking.—Witness said that the electric lighting undertaking was acquired in 1896, £400,000 being paid for what had cost the company £250,000. The charges for current by the company had been 7½d. per unit for lighting and 5d. for power. These charges had been reduced by the Corporation to 4d. for small customers and 3d. for public buildings for lighting, while large consumers for power were charged only 2d. per unit. It had been found possible to work the tramways and the electrical undertaking together, with the result that the charge made to the tramway undertaking for power was less than 1d. per unit. The Corporation's profit in 1896 on the company's charges was £11,000. Last year, after the charges had been twice reduced, the profit remained the same. None of this profit had been allocated to the relief of the rates. Under no circumstances could more that 5 per cent. of the profits be taken for this purpose, because when a larger profit was shown the price had to be reduced. Witness went on to say that he recognised the danger arising from the growth of the number of municipal employés who had votes, and he did not see that any great hardship would result if, on a man becoming an employé of a corporation, he ceased to have a voice in the choice of his masters.

By the CHAIRMAN: Where a local authority got an electric lighting or tramway order they should be called upon to exercise it within a reasonable period, or forego it. If the order was merely obtained as a block it should be set aside.

Ald. SOUTHERN, of the Manchester City Council, said he had served on both the Waterworks and the Gas committees of the Corporation, and was a representative of the City Council on the Manchester Ship Canal Board. Last year the great expenditure incurred in connection with the Thirlmere water scheme had all been wiped out, and it was found possible to reduce the water charges to consumers by £35,000 per annum. With regard to gas, the Corporation made an annual average gross profit of £105,572, which was devoted to the reduction of the city rate. As something had been said by a former witness respecting the ability of corporations to manage gas undertakings, he might say that during the last 50 years the consumers of gas in Liverpool, where the supply was provided by a company, had paid 3d. per 1,000 more for their gas than consumers in Manchester, where the gas supply had been in the hands of the Corporation since 1843. The ratepayers in Manchester, so far from having sustained losses by reason of having their gas cheaper had paid over out of the gas account towards City improvements a profit of £788,317, besides writing off £631,494.

The CHAIRMAN: If you devoted the whole of your £100,000 profits to reduction in price, what would be the effect?—Witness: One penny in the £ is equal to £12,000, so that it would make a difference of about 8d.

The Committee again adjourned till to-day (Friday).

HULL TRAMWAYS.

On June 28 the bill for the confirmation of the provisional order obtained by Hull Corporation with regard to owning and working tramways came before the Select Committee of the House of Lords, of which the Duke of Northumberland is chairman.

Mr. BALFOUR BROWNE, Q.C., said this was an order authorising the Hull Corporation to construct additional tramways in the city. The Corporation having purchased the Drypool and Marfleet steam tramway, which was a single line, applied for a provisional order giving them power to reconstruct the line as a double line throughout and working it electrically on the overhead trolley system. The line ran along the north side of Alexandra Dock, so that the line was a very important one. There were trams in all the main thoroughfares of Hull, and they crossed in about a dozen places the lines of the North-Eastern Railway on the level. All that was now proposed at the level crossing in Heddon-street was to double the line and to work it by electricity. A single line ran over the railway line there already, yet the North-Eastern Railway Co., because they had an easement to run their trains across the road on the level, instead of by some other means, objected. The Drypool and Marfleet Company was a very small and insignificant concern compared with the North-Eastern Railway Co., and so, when getting power to cross the railway—conceded as the price of the withdrawal of the railway company's opposition—very strong clauses indeed for the protection of the company were inserted. These clauses included such things as that the goods traffic from the railway company's dock should have precedence of traffic on the tramway company's own road—a monstrous provision; that the railway company were not to be obstructed; and that the railway company should have power to make their own byelaws for their own protection on the

Digitized by Google

tramways. These provisions were to be taken over by the Corporation, and while counsel did not dispute them he did say that they should get no further protection. The railway company, as an answer to the present application, in their petition referred to sec. 25 of the Act of 1893 under which, if Hull found it essential there should be a bridge at this level crossing in order to carry the road over the railway, then the railway company should contribute two-thirds and the Corporation one-third of the cost. They said that clause should be enforced. The reason the Corporation did not use that power was that they held there was no danger whatever at the crossing. There were no passengers carried over the line, which only ran to the docks ; and if there were danger then the railway company themselves were bound at their own expense, by the Act of 1852, to build the bridge. A bridge in that position would be very inconvenient, because all the traffic on the road was very heavy, and the gradient which the bridge would cause would necessitate the putting on an extra power and cause serious blocking of the traffic. The electric tram could easily run up such a gradient as would be involved—1 in 40 ; but the Corporation objected because of the general inconvenience to the public. It would be said that the Hull Corporation drivers had in one or two cases touched the gates at the level crossings with their cars. This was admitted, but in every case where there was a gate the Corporation had now marked in the street the distance from the gate at which the car was to be stopped. That was found to be perfectly efficacious, no damage having resulted except in one slight case.

Mr. LAVERACK, town clerk of Hull, said when this line had been purchased all the trams in Hull would be in the hands of the Corporation and be worked electrically. The Corporation opposed the abolition of the level crossing because it would add largely to the cost of haulage, and alter that which governed the amount of load which could be carried generally through Hull. It would be an advantage to the road traffic to get rid of the level crossing ; no one could deny that level crossings *per se* were most objectionable. Catch points had been introduced, the effect of which was that if a tram overran the point where it ought to stop it would run off the line. The Corporation thought that was reasonable, the Board of Trade having assented to it. They could just as well bring up the tramcar before a catch point as before a railway. There had been two or three cases in which cars had overrun the catch points and run off the line owing to the carelessness of the drivers. Electric cars were under such great control that drivers over-estimated what it was possible to do with them.

Mr. W. H. WELLSTED, C.E., said he was engineer to the Drypool and Marfleet line. As to the crossing in dispute, traffic had been regularly carried on since its erection without interference or hindrance to the railway company's traffic. The gates at the crossing were closed entirely during shunting operations. The weight of a steam engine and car was greater than that of the electric cars the Corporation were running, and the brake power of a steam train was not nearly as efficient as that of a steam car.

Mr. STEPHEN SELLON said he had been professionally associated with a large number of tramway companies which worked over level crossings, and he knew of no accident due to working over a level crossing. It was common for tramways to cross tramways at right angles, but not very common for trams to cross trainlines belonging to other companies.

Is there any danger to the public by the use of electric traction over this crossing ?—None at all, under proper control.

Is there any danger to the public by substituting a double line for a single line ?—No, it is much more satisfactory in all systems of electric traction, and much safer where a frequent service is intended. An electric car had far more braking capacity than any other modern tramway car.

So far as electric trams cross railways—which was the best ground of complaint, if any ground of complaint there be ?—I have never yet been able to understand what the railways really complain about. The railway company has the whole control of the level crossing while the gates are across the road and, as far as my experience goes, the tramway companies rather want a clause for their own protection to prevent them being unnecessarily stopped at crossings where railway companies use those crossings illegally for the purposes of shunting. He had had many cases in which level crossings were sanctioned by Parliament. He had never seen such a clause as that which existed for the protection of the North Eastern Company—he called it monstrous. If there was any danger at all at level crossings it would be greater where there were only two or three trains passing daily than where there were many, because in the former case the men might be liable to forget the trains.

Mr. GOODYEAR, traffic manager to a very large number of tramway undertakings, worked by electric power, by steam, and by horses, said there were level crossings on those lines, some over railways, and they were worked satisfactorily and without accident.

Mr. A. E. WHITE, city engineer of Hull, and engineer to the present scheme, said at present the tramway line crossed the railway ; if a double line were carried across it would lessen the stoppage of cars at the crossing and thus facilitate road traffic, and prevent the danger of blocks on the railway. Electric cars were under much better control than steam cars. A road bridge would be most disastrous to the road traffic. There were three or four bridges in Hull at present, but they were dodged, and practically no heavy traffic passed over them. There would be almost as much objection to a tunnel as to a bridge. If the bridge had an incline of 1 in 40, about three times as much power would be required to mount it as would be required on the level, and great difficulty, if not danger, would be experienced in taking the vehicles down the incline, as, owing to the general flatness of Hull, vehicles were not generally fitted with brakes. For the past 12 years there had been no accident at this crossing. The lines at the crossing-place were largely used for shunting, which was an improper use of the public roads. There had been a number of small accidents at the level crossings in Hull, but they were due to carelessness and to the newness of the electrical scheme. As, however, the Corporation had gone on working they had made the regulations as stringent as was found desirable. Catch-points, if the railway company thought them desirable, would afford the railway company ample protection.

This closed the case for the promoters.

Mr. MOON, for the North Eastern Railway Co., said this question of the extra cost of cartage, owing to a bridge being provided, if there was anything in it, would affect the North Eastern Company more than anyone else, as they were the largest carters in Hull, so that the company could not be said to have any interest opposed to the interest of the witnesses who objected to the construction of a bridge. The level crossings at Hull had been the subject of constant complaint by the Corporation. The railway company were willing to provide two-thirds of the expense of constructing a bridge, which would obviate all the difficulties and delays and dangers (if dangers existed) at the crossings, and enable the Corporation to have a through run for their trams instead of being practically at the mercy of the railway traffic. Was the Committee satisfied there was no danger in allowing electrically-propelled cars to cross a railway on the level ? It might be safe, with proper precautions inserted by the Board of Trade, where there were few trains ; but in a case where there were 260 engines, with or without trucks behind them, passing daily, surely it was entirely different. There had been no accidents at Hull or at Stockton while the cars were run by steam ; but, whatever the cause, as soon as electric traction was introduced there were accidents. He asked the Committee to say the crossing should be got rid of, and that as the price of obtaining the power they sought the Hull Corporation should be obliged to contribute one-third of the cost of the necessary bridge.

Mr. GEORGE GIBB, general manager of the North Eastern Railway Co., explained that the clause in the Drypool and Marfleet Order for the protection of the North Eastern, which had been referred to as monstrous, was not suggested by the North Eastern Company, but was put in by the Board of Trade, following the precedent of the Wigan Order, at that time the most recent. In the former bill (which did not become law) a clause was agreed to by the Corporation for the erection of a bridge at this place with a gradient of 1 in 40, as was now proposed. Such a gradient was found in practice not to limit a load or prevent the regulation load of 2½ tons being drawn by one horse. The crossing in question was even more dangerous than it would be if passenger trains used it. Lines for passenger traffic were worked on the block system, so that the working was more regular, and the gates were closed when the train was still several hundred miles from danger. At the Hedon-road crossing the engines and trucks were being continually shunted backwards and forwards ; and often it was not the engine driver or his engine which crossed the points at the crossing but the trucks behind the engine, and so there was greater danger. Moreover, the gates here were so often closed that it would be impossible for the tramway to carry out their scheme of a three-minute service. The directors of the North Eastern Company had been seriously alarmed by the electric tramways. They had not objected to electricity being introduced in the Stockton case, but it was very curious that, whatever the reason, after electric traction was introduced accident after accident occurred there ; and the same result followed the introduction of electricity in connection with the trams at Hull. He proceeded to read a list of the cases in which accidents had occurred at both places. So serious and numerous were these that the directors of the railway company were afraid of the prospect. No railway would be permitted to cross another line of railway at the present time, and in cases where such an arrangement was continued the traffic was worked on the block system. Whatever the control a tramcar driver had over his machine, that control, as shown by the accidents, was often not sufficiently exercised ; and unless some system in regard to electric trams similar to the block system was established, he did not see how these accidents could be avoided.

From the experience you have had of the conduct of these cars in crossing your railway, are you strongly of opinion, as the responsible manager of the railway, that it is a very dangerous thing to allow it to be done ?—Yes. We have been seriously alarmed by these accidents. The railway company were willing to pay two-thirds of the cost of the bridge, so anxious were they in regard to this point. Two level crossings in Hull had been abolished on the same terms.

Further evidence was given by Mr. H. Copperthwaite, engineer of the southern district of the North Eastern Railway, and by Sir John Wolfe Barry, consulting engineer to the North Eastern Company.

The CHAIRMAN said : The Committee do not see their way to granting electricity or a double line at this particular crossing and do not see their way to pass so much of the bill. In their opinion some definite proposal should be made of a give-and-take kind as to raising the railway and lowering the road before Parliament should be called upon to give the powers asked for.

Mr. LLOYD, for the Corporation : I understand the Committee will neither sanction electricity nor a double line. Would a single line meet your objection ?—No.

On Monday, Mr. PEMBER said he hoped an agreement had been or would be come to between the parties which would enable the tramway to pass the railway, the suggestion being that the road should be lowered and the railway line raised, so as to allow a workable gradient. This agreement must be sanctioned by the Corporation, which did not meet till Thursday. If the agreement was sanctioned by the Corporation, he suggested that he (the Chairman of the Committee) personally should pass the requisite clause, it being understood that if the Corporation did not accept the agreement the whole order would be withdrawn.

The draft of the clause to be submitted to the Corporation was handed to the Chairman to be submitted to the Committee. This clause provided that tramway No. 2 (the one passing along Hedon-road) should not be laid, nor should electric power be employed on that part of Hedon-road where it crossed the railway unless and until the railway had been carried over the road by means of a bridge, such bridge and works in

Digitized by Google

connection therewith to be constructed, unless otherwise agreed, in accordance with certain heads of arrangement. The level crossing at Hedon-road was to be abolished by raising the Victoria Dock branch railway at this point not less than 7ft., and carrying the same over the road by a bridge, and by lowering the roadway of Hedon-road so as to obtain a clear headway under the bridge of 16ft. 3in., the gradients for the road to be not steeper than 1 in 40, the footpaths to remain unaltered as far as reasonably practicable, and to be connected with the lowered roadway by steps, the entire width of the new road to be not less than 58ft. The railway company were to seek in the next Session of Parliament and use their best endeavours to obtain powers necessary for carrying out the said works, the Corporation to assist the company in such application to Parliament.

The Committee accepted the provisions.

The CHAIRMAN: It must be understood that the Corporation take the clause or leave it. I will not be responsible for any alteration.

Further proceedings were adjourned till to-day (Friday).

AIRDRIE AND COATBRIDGE TRAMWAYS BILL.

The Select Committee of the House of Lords, presided over by Lord Ribblesdale, on June 26, considered this bill.

Mr. FREEMAN, Q.C., for the promoters, said the Caledonian and North British Railway Companies had withdrawn their opposition, and the only opponents left were the Airdrie and Coatbridge Water Co. The original scheme included Coatbridge, but as the local authority had refused its consent that portion of the bill had been withdrawn, and the bill referred to Airdrie alone. The water company, he urged, were amply protected under the Tramways Act, 1870.

The CHAIRMAN said the Committee were of opinion that the water company had no *locus standi*, and the engineer of the scheme, Mr. I. E. Winslow, having proved the details, the Committee found the preamble proved. The bill was afterwards ordered to be reported.

LONDON TELEPHONE SERVICE.

In the House of Commons on Friday last Mr. HANBURY stated, in reply to a question, that the construction of the underground system of wires for the Post Office telephone service for the metropolis was proceeding as rapidly as possible. The subscription rates would be published as soon as the Postmaster-General was able to announce a definite date for the opening of the main exchange.

(Parliamentary Intelligence continued on page 411.)

ELECTRICITY WORKS ACCOUNTS.

Belfast Municipal Electric Supply Works.

Our summary of the accounts of the Belfast undertaking for 1899 clearly shows the difference wrought by the conversion from gas to steam working. The effect is less apparent from the accounts because during 1898 the supply was generated partly by gas and partly by steam—the steam station having been started in July of that year. An interesting comparison is therefore afforded by the annexed table.

It will be seen that although, as between 1897 and 1899, both the output and the load-factor have increased, yet the difference was quite inadequate to cause the alteration which has taken place in the costs—especially in the fuel item.

The results obtained last year are, without exception, excellent, not only as regards the expenditure figures but also in the marked advance in the business done. At 622,486 units sold the output was nearly 75 per cent. above that of 1898 while the equivalent lamp connections show a rise of nearly 34 per cent.

The following table furnishes some interesting figures relative to this undertaking:—

Year.	Units generated.	Units sold.	Maximum supply demanded. Kw.	No. of lamps connected. (Equiv. 8 c.p.)	Rev. per unit for current.	Works costs per unit sold.	Total costs per unit.	Plant capacity. Kw.
1895	95,126	82,771	159	10,500	6·32d.	3·47d.	5·43d.	283
1896	166,219	149,721	240	14,750	6·30d.	2·93d.	4·01d.	500
1897	235,972	201,832	360	21,000	6·04d.	2·63d.	3·54d.	500
1898	414,007	356,526	721	38,500	5·41d.	2·18d.	2·92d.	900
1899	742,590	622,486	956	51,500	4·36d.	1·52d.	2·22d.	2,080

The Hove Electric Lighting Co. (Ltd.).

We are glad to find from the Hove accounts for 1899 that the already flourishing state of the undertaking is being so well maintained. As a glance at our table on next page will show, a general reduction in the costs has been effected. The items of rents, rates and taxes, and fuel are exceptions, having risen slightly; but in view of the upward tendency of coal prices during the last two or three years, it is most satisfactory to find the fuel item exhibiting such a moderate figure as it does.

As largely contributing to the improvement in the costs attention is directed to the good advance made in the output, which rose from 350,354 units sold in 1898 to 444,499 units last year. The character of the load was also more favourable, as is shown by the load factor having risen from 9·85 per cent. in 1898 to 10·9 per cent. The lamp connections indicate an advance of over 31 per cent.

In view of this expansion of business, it is not surprising to find from the report of the directors that, although two additional steam dynamos of 350 H.P. and 250 H.P. respectively and a Babcock and Wilcox boiler have been installed, while another 250 H.P. steam dynamo is on order for delivery in the autumn, yet it has become necessary to seek for a site for a second generating station, as the present one has been enlarged to the fullest extent which the Corporation of Hove will permit.

The following figures furnish an idea of the progress which this concern has made since 1896:—

Year.	No. of consumers.	No. of lamps.	No. of units sold.	Max. supply demanded. Kw.	Total costs per unit.	Total revenue per unit.
1896	314	21,756	230,562	253	3·85d.	7·93d.
1897	397	27,777	268,243	310	2·93d.	6·51d.
1898	513	36,967	350,254	406	2·88d.	6·50d.
1899	671	41,824	444,499	465	2·60d.	6·52d.

The following is a list of electric supply works the accounts of which have been analysed, together with the dates on which statements and analyses of accounts have appeared:—

Aberdeen (Municipal)	Jan. 12, 1900	Kingston-on-Thames (Mun.)	April 21, 1899
Ayr (Municipal)	Sept. 22, 1899	Lancaster (Municipal)	Jan. 19, 1900
Bath (Municipal)	April 20, 1900	Leeds (Municipal)	Dec. 1, 1899

BELFAST.—REMARKS—*a* Being 256,998 units at 7d., 3,986 units at 5d., and 50,531 units at 2d. for lighting; 26,045 units at 4d., 14,069 units at 2¾d., and 4,760 units at 1¾d. for motors; also 137 units at 6d. for charging batteries. *b* Includes £225 for copper scrap and £513 from miscellaneous sources. *c* Inclusive of £52 on street arc lamps. *d* Over-expended. *e* Gas and coal. The gas to generate 195,000 units cost £992 or 1·22d. per unit and the coal to generate 161,526 units cost £592 or 0·879d. per unit. *f* Includes insurance £121. *g* Being amount contributed to renewals suspense account. *h* After deducting hire of gas engines returned £515. *i* On Wright system with 1½-hour scales. *j* Includes 278,515 units at 7d., 8,087 units at 5d., and 255,631 units at 2d. for lighting purposes; also 25,500 units at 4d., 20,289 units at 2¾d., and 28,152 units at 1¾d. per unit for motors; also 120 units at 6d. for charging batteries. *k* Includes £244 from sale of copper scrap and for work done. *l* Gas and coal. The gas to generate 22,000 units cost £277 or 3·02d. per unit and the coal to generate 600,486 units cost £1,478 or 0·557d. per unit. *m* Includes insurance £104. *n* On Wright system with one-hour scale.

HOVE.—REMARKS—*a* Over-expended. *b* Distribution wages and repairs and maintenance are included in the corresponding generating items. *c* Includes £11 to auditing and £149 to insurance. *d* Set aside under contract with the Hove Commissioners. *e* After deducting £248 written off preliminary expenses. *f* By the Wright system (one-hour scale). *g* Inclusive of premiums received £8,188. *h* Includes £450 directors' remuneration. *i* Includes £150 for insurance and £11 to auditing. *j* After deducting £262 written off preliminary expenses and £97 income tax.

The Electrician.

The Oldest Electrical Journal (established as a weekly Journal 1861—1878

Published every Friday, Price Sixpence; Post Free, Sixpence-Halfpenny.
Editorial Publishing and Printing Offices,

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.

Telephone: 949 Holborn. *Telegrams:* "ELECTRICIAN NEWSPAPER LONDON."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed "Coutts and Co."*

All Editorial letters to be addressed to THE EDITOR.

All letters for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer as evidence of good faith. No notice whatever is taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices, as above*

Subscription Rates.—The Rates for Subscriptions to "THE ELECTRICIAN" are as under:—

	YEAR	HALF-YEAR	QUARTER	
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.	Post free, payable in advance.
Postal Union ...	30s. 0d.	16s. 0d.	8s. 0d.	

New Volumes of "THE ELECTRICIAN" *commence in April and October.*

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.** *This statement is guaranteed.*

Advertisement Rates, &c., forwarded on application to the Publisher.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Office not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday. Wrapper Advertisements by Wednesday morning.*

OFFICIAL ANNOUNCEMENTS, AUCTIONS, *and* SMALL ADVERTISEMENTS *accepted up to* **6** *p.m. on Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of THE ELECTRICIAN" *Printing and Publishing Company, Limited. The well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works at present consists of—*

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. ELTON YOUNG, M.I.E.E. Price 10s. 6d., post free; abroad 11s.

THE STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By Messrs. H. K. C. FISHER and J. C. H. DARBY. Price 6s. net; abroad, 6s. 3d.

BIBLIOGRAPHY OF X-RAY LITERATURE AND RESEARCH. Edited by C. E. S. PHILLIPS. With an introduction on the history of Crookes Tube and Röntgen Ray work, and a chapter giving "Practical Hints" on the subject.

THE POTENTIOMETER AND ITS ADJUNCTS. By W. C. FISHER. Price 6s., post free.

LOCALISATION OF FAULTS IN ELECTRIC LIGHT MAINS. By F. C. RAPHAEL. Price 5s., post free.

MOTIVE POWER AND GEARING. By E. TREMLETT CARTER. Price 12s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. WILKINSON. Price 12s. 6d., post free.

ELECTRICAL LABORATORY NOTES AND FORMS (Elementary and Advanced). Arranged by Dr. J. A. FLEMING, M.A., F.R.S. Printed particulars on application.

ELECTROMAGNETIC THEORY. By OLIVER HEAVISIDE. Vol. I. Price 12s. 6d., post free 13s. Vol. II. Price 12s. 6d.; post free, 13s.

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING. VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. NEW EDITION. Price 12s. 6d., post free. VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. FLEMING, M.A., D.Sc., F.R.S. New Edition. 93 original illustrations, price 6s

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. EWING, M.A. New edition. Price 10s. 6d., post free.

ELECTRIC MOTIVE POWER. By A. T. SNELL. 10s. 6d. post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. WEYMOUTH. Price 7s. 6d. post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By GILBERT S. RAM. Price 7s. 6d., post free.

POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. GEIPEL and H. M. KILGOUR. Price 7s. 6d. net, post free 7s. 9d., abroad 8s.; large-paper edition, 12s. 6d., post free. New edition in the press.

"THE ELECTRICIAN" PRIMERS. In Two Vols. Paper covers, 2s., post free 2s. 2d. each; strong cloth 2s. 6d., post free 2s. 9d. each. Single Primers 2d., post free 2½d.

WIRELESS TELEGRAPHY: SIGNALLING ACROSS SPACE WITHOUT WIRES BY ELECTRIC WAVES. By Dr. O. J. LODGE. New Edition. Price 5s. net.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING, ELECTRIC TRACTION, TELEGRAPHS, TELEPHONES, &c. A. C. CURTIS-HAYWARD, B.A. To January, 1900. Price 3s. 6d., post free.

CARBON MAKING FOR ALL ELECTRICAL PURPOSES. By FRANCIS JEHL. Price 10s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d., post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 3s. 6d., post free.

FULL CATALOGUE POST FREE ON APPLICATION.

"ELECTRICIAN" SERIES FORTHCOMING BOOKS.

THE ELECTRIC ARC.—By Mrs. AYRTON. This work is in the press, and will contain an historical sketch of the early experiments on the electric arc, as well as the important results of recent research.

PRIMARY BATTERIES.—A work on this subject will shortly be published bringing the theory and practice of the Primary Battery up to date. The book will be fully illustrated.

SECONDARY BATTERIES.—By E. J. WADE. Fully illustrated. The Author in this work will deal briefly with the theory and fully with the chemistry, design, construction and manufacture of secondary batteries or accumulators.

"THE ELECTRICIAN" WIREMAN'S POCKET-BOOK.—Edited by F. C. RAPHAEL. "The Electrician" Company will shortly publish a valuable pocket-book for the use of those engaged in wiring work, both external and internal.

THE TELEPHONE.—By DANE SINCLAIR and F. C. RAPHAEL.

SPECIAL NOTICE.

NOW READY.—Vol. XLIV. of "THE ELECTRICIAN" (950 pages), bound in strong cloth. Price 17s. 6d., post free 18s. 6d. Also ready, Cases for binding. Price 2s., by post 2s. 3d.

A complete set of "THE ELECTRICIAN" (1878-1900) can now be supplied. These sets are very scarce, and early application should be made.

THE ELECTRIC POWER BILLS.

IN our last issue we announced that the Select Committee of the House of Commons, presided over by Sir JAMES KITSON, had decided to pass the preambles of three of the four large electric power schemes, rejecting only the preamble of the Tyneside scheme. When making this announcement Sir JAMES KITSON further stated that so far as practicable uniform conditions would be inserted in the various bills. We have now to direct the attention of our readers to an additional statement on this matter, made by Sir JAMES KITSON on Tuesday last. The statement, so far as its direct bearing is concerned, was made in respect of the South Wales Electrical Power Distributing Co.'s scheme; but, having regard to the intended uniform treatment of all the schemes, its bearing will probably be found to be of a much wider and more general character. The statement is substantially as follows:—

I have to make a statement which is an expansion of the previous declaration of the Committee on the South Wales Electrical Power Distribution Bill. It is as follows: (1) The company to be authorised to supply electrical energy for power purposes anywhere within the area of supply, subject to the consent of the local authority in certain cases, as set out below. (2) The company to have no general lighting powers—*i.e.*, distribution to ordinary consumers within the area—except in pursuance of a provisional order obtained in the ordinary way. (3) Where a local authority is now authorised to supply electricity within the area, their consent is to be required for the supply of electricity by the company. The Board of Trade to be empowered to override the refusal of the local authority to give consent, if the authority are not prepared to provide the requisite supply on reasonable terms and within a reasonable time. (4) Any local authority which hereafter gets statutory powers for supplying electricity within the area to have, in ordinary cases, the option of taking over the company's supply in its local area on terms to be laid down by the provisional order or act by which the statutory powers are given. (5) A company having statutory powers, to be in the same position as a local authority now having statutory powers; a company to whom powers are hereafter granted, to be placed in the same position as a local authority to whom statutory powers are hereafter granted.

Provisionally we may assume that this statement expresses the conditions for all future power supply schemes, powers for which are not directly obtained under the Electric Lighting Acts (1882-8), *i.e.*, all schemes supplying power wholesale over an extensive area. Let us see what these conditions imply. Condition No. 1, taken by itself, seems at first glance satisfactory. The power company is to be allowed to supply electricity for power purposes, subject to certain consent

Digitized by Google

from the local authority. Condition No. 2, however, narrows down the apparent privilege. Power *quâ* power may be supplied to a factory or other consumer; but the electric power so supplied is not to be used for electric lighting, unless the company has previously obtained a lighting order for this particular part of its area. A manufacturer taking motive power from the company may therefore be compelled to go to the local authority for lighting current, to be taken from an altogether different power station from the company's power station. But if a manufacturer may erect an electric motor and shafting to run his works, what is to prevent him from running a small dynamo from that same shafting and so lighting his own premises? The Board of Trade would be powerless to prevent this practice.

Coming to condition No. 8, we see that the Board of Trade is to be granted the power to overrule the obstruction of any local authority to the introduction of electric power by the company. This is a very wise and, indeed, a most necessary decision. The next condition (4) specifies that terms are to be introduced into the sectional orders—*i.e.*, the provisional orders for any section of the entire area—upon which terms the local authority may at any future time take over that part of the company's business which relates to electric supply within the area controlled by the local authority. The justice of this provision will depend on the precise nature of the terms introduced into each particular order; but the provision is almost certain to lead to friction between the company and the local authority in drawing up the terms referred to. It is conceivable, moreover, that where opportunity arises a local authority might succeed in introducing terms that would seriously hamper the ordinary business of the company. It would appear also that existing local companies holding lighting orders are to be put on the same footing in this respect as local authorities in the same position, and that a company which in future may obtain a lighting order is to be treated in the same way as a local authority thus obtaining an order. We presume this means that a local company is, like a local authority, to have power to take over the local business of the general power company on certain terms to be embodied in the provisional order. The effect of these complicated transferences of local sections of a business grown large and extensive cannot well be imagined.

THE NEW CABLE-REPAIRING STEAMER "JOHN PENDER."

The Eastern Telegraph Co.'s new cable-repairing steamer "John Pender" is now completed, and fully equipped and ready to proceed to sea. She will, in fact, start for a foreign station on Saturday. The launch of this steamer took place at Glasgow, on March 13 last, when the vessel was christened the "John Pender," the ship of that name formerly in the company's fleet having been disposed of. A description of the new steamer appeared in our issue for March 23 last, but since that date the equipment of the vessel has been completed, and some further particulars regarding her will interest our readers.

The "John Pender" is not only the newest but also the largest and most perfectly equipped of modern cable-repairing steamers. Her length all over is 333ft. 9in., and the length on the load line 300ft. The beam outside the plank is 41·2ft., the depth of the hold from the tonnage deck to the ceiling amidships is 25ft. 6in. The gross tonnage is no less than 2,836 tons, the registered net tonnage being 1,104 tons. She is splendidly engined with 3,500 I.H.P., capable of developing a speed of 14 knots at the ordinary working draught—an accomplishment which she readily made on the measured mile. The vessel, was built and engined by Messrs. Robert Napier & Sons, of Govan, Glasgow. It should be stated, however, that the owners are responsible for the design of the vessel, engines, &c., and of her complete equipment, the whole being the result of many years of thought, discussion and experience on the part of the company and its chief officials. The ruling principles in her design and construction have been (1) to do all the work of the Eastern and allied companies in all parts of the world either in deep or shallow water, which at present no one cable-repairing steamer can do, although many of them are of much smaller size than the "John Pender." (2) To embody all the collected and collateral experience of the company, extending over many years, in regard to their fleet of ships, with the addition of all known and tried improvements, bringing vessel and engines up to date, with the object that the cost of maintenance shall be kept at the lowest possible point. Nothing that would further this end has been spared in the capital outlay on the vessel. Coal endurance is a point which has been carefully regarded, the vessel having 15 days coal capacity at full speed, with cables and stores for ordinary repairing work. She is provided with five cable tanks, one being auxiliary, and is, therefore, capable of carrying a very large amount of cable—about 1,000 tons when on ordinary cable-laying and repairing work, and about 2,000 tons when engaged on special service. When using only two of her boilers she is capable of a 10 knot to 10½ knot sea speed. Many important points have been held in view in regard to (1) the main design of the vessel, (2) the equipment of her engines and auxiliary engines, (3) the cable laying, repairing, and testing departments, and, lastly, in regard to the hygienic and general sanitary conditions of health and comfort. In all these respects the arrangements on board could not be surpassed. The hospital and medical arrangements are specially complete, the hospital containing isolation cots of the best Admiralty pattern, besides other equipments necessary for the treatment of disease or surgical cases in tropical climates. The watertight compartments of the bunkers are arranged to be closed promptly by an ingenious mechanism.

The main engines were built by the builders of the ship, Messrs. Robert Napier & Sons. They consist of two triple-expansion marine engines, each driving a separate propeller. These propellers are of the Navy bronze type, supplied by Messrs. Stone, of Deptford, who also supplied the watertight doors and some portion of the sanitary fittings. The engine and boiler equipment includes two 12-ton evaporators by Messrs. Caird & Raynor, a feed-water heater by Messrs. Kirkcaldy & Co., centrifugal pumps by Messrs. Drysdale & Co., of Glasgow, main feed pumps by Messrs. G. & J. Weir, of Glasgow, each pump having the full capacity of the boilers, besides some auxiliary pumps by Mr. A. G. Mumford, of Colchester. The boilers are supplied with air by Howden's forced draught worked by a 90in. fan, and two compound high-pressure auxiliary engines. The electric lighting of the ship is as perfect as modern practice can make it, and has been carried out by Messrs. Clarke, Chapman & Co., of Gateshead-on-Tyne. This firm have also supplied the lifeboats, the sides of which are formed from one sheet of metal, experience having proved this to be the best type of boat. It will be remembered that the only boat saved from the ill-fated "Mohegan," wrecked on the Manacles, was a lifeboat of this pattern. The electric lighting sets consist of two continuous-currrent dynamos, each with its separate direct-connected vertical steam engine. Each set has a capacity of 250 lights. The powerful searchlight is also supplied by the same firm. This plant, together with the necessary main switchboard, &c., is placed in a separate machinery room between decks, thus isolating the dynamos from the heated main steam engine room. The refrigerating plant, which embodies all the latest improvements, has been supplied by Messrs. J. & E. Hall, of Dartford.

It is unnecessary to state that the steamer is perfectly equipped with cable-handling and testing apparatus. The engines for the cable gear were built by Messrs. Robey & Co., of Lincoln. The instruments and general equipment in the

Digitized by Google

testing room are of the latest pattern Kelvin testing instruments by Messrs. James White, of Glasgow, this firm having also supplied the nautical instruments.

At the present moment the "John Pender" is berthed alongside the old cable steamer "Chiltern," in the South West India Dock. The spectacle is thus afforded of the oldest and the newest cable-repairing boats in the world lying side by side. The "John Pender," however, will not long remain in this berth, although it is only 10 days since she was brought round from the Clyde out of the hands of her builders, for, as already stated, she is commissioned to proceed to a foreign station next Saturday on work for the Eastern Extension Telegraph Co.

POWER SUPPLY BY SINGLE-PHASE MOTORS.*

BY T. P. WILMSHURST.
(Borough Electrical Engineer, Derby.)

The principal objections which are usually urged to the distribution of electricity by alternating currents are: (1) That alternating-current is less economical than direct-current working. (2) That alternating arc lamps are inferior to direct-current lamps. (3) That single-phase motor working is impracticable. While the writer is prepared to admit that in some instances objections (1) and (2) are valid, and (3) also in a modified degree, he holds the conviction that they originate rather from unsuitable arrangements or want of appreciation of the varied requirements of electrical supply on the part of the designers, than from any inherent unsuitability of alternating currents. He is led to this conclusion from a study of the cost's analysis of various towns, from which it appears that the following results have been achieved in A.C. stations: Full costs of 0·25d., 0·3d., and 0·32d., and works costs of 0·78d., 1·02d., and 1·16d., all on outputs of less than a million units per annum. As regards objection (2) the writer would only remark that those members of the Association who visited Cheltenham during the last Convention would hardly deny that the A.C. arc lighting there left little to be desired. Coming to objection (3) the object of the Paper is to show what is the present position of the S.P. motor in the struggle for existence.

In nearly every town, certainly in all manufacturing towns, there will in the future be an enormous demand for motors when the cost of supply is sufficiently low and the public appreciate the advantages of electric driving. Since the S.P. system has been adopted in nearly 100 towns in this country, the question arises, how is this demand to be met? (1) Shall we change over our whole system to D.C. as is proposed in one or two cases? (2) Shall we lay down D.C. plant and mains for the motor supply, leaving the A.C. plant to supply current for lighting? (3) Shall we supply S.P. motors from our ordinary A.C. plant and mains? (4) Shall we lay a special A.C. motor network supplied from the A.C. plant. (5) Shall we lay down multiphase plant for power supply? The writer has come to the conclusion that while cases do exist in which by reason of abnormal frequency, excessive armature drop in the generators, or other causes, the good working of A.C. motors is rendered difficult, in the majority of cases, under reasonably favourable conditions, the inferiority of the S.P. motor to the D.C. or three-phase motor is not sufficiently marked to justify the laying down of special plant. It is obvious that method (3) has the great merit of simplicity and low cost. It is a matter of common knowledge that at the present time, while the proportion of motor to lighting load on D.C. circuits is small, it is still less on A.C. circuits, and it is a matter of interest to study the causes of this. The two principal reasons appear to be the difficulty of successfully competing in cost with gas and steam engines, and the fear that the use of motors will injuriously affect the steadiness of the light. It is a self-evident truth that the more the day load can be increased the lower can the charges be made. An examination of the power charges in various towns reveals the curious fact that these charges vary from 8d. per unit down to 1d., and inasmuch as the cost of production can hardly vary within such wide limits, it would appear that the size of these charges is a measure of the appreciation by the engineer of the value of a motor load. In the case of a gas engine a brake horse-power can be obtained for about 1d. per hour; in the case of electric motors, therefore, it is necessary to bring the cost down to 1d. to 1½d. per unit before we can hope to enter into successful competition. The second point is of vital importance, and merits careful consideration.

The principal causes which are likely to disturb the supply voltage are: (*a*) Bad regulation in engines, alternators and transformers; (*b*) the use of small generating sets and transformers; (*c*) defective working of the motors themselves; (*d*) the adoption of a high frequency. The first is a prolific source of trouble. An armature drop of 20 per cent. to 30 per cent., even on non-inductive loads, is by no means uncommonly found in this country. Why these abnormal drops of pressure have been tolerated it is difficult to say. It is obvious that the starting of a large motor on mains supplied by such a machine must cause an instantaneous drop of pressure which no amount of switchboard manipulation can prevent. When one considers that in a D.C. station an armature drop of 6 per cent. is rarely exceeded, is it any wonder that A.C. motor working on such circuits has been discouraged? A similar abnormal drop may also be found in transformers which have been designed for a lighting load only. It is quite possible that a transformer with heavy magnetic leakage may have three or four times the terminal drop on a motor load which it would have on a lamp load. It is therefore obvious that all transformers before being sent out should be tested on an inductive load in addition to the non-inductive load test. The writer has adopted the practice in specifying for transformers that when tested on a non-inductive load the drop shall not exceed 2 per cent., and not more than 3 per cent. when tested on a load with a power factor of 0·75. (*b*) The question of the size of the day load sets is one which will right itself as the motor load increases, since the possibility of any single motor disturbing the supply will diminish as the number of motors increases, and this may therefore be classed as a temporary difficulty only. (*c*) The chief defects are heavy starting current and low power factors. The starting current in a S.P. motor need not necessarily be abnormal, though undoubtedly this often is the case, and it is surprising that A.C.

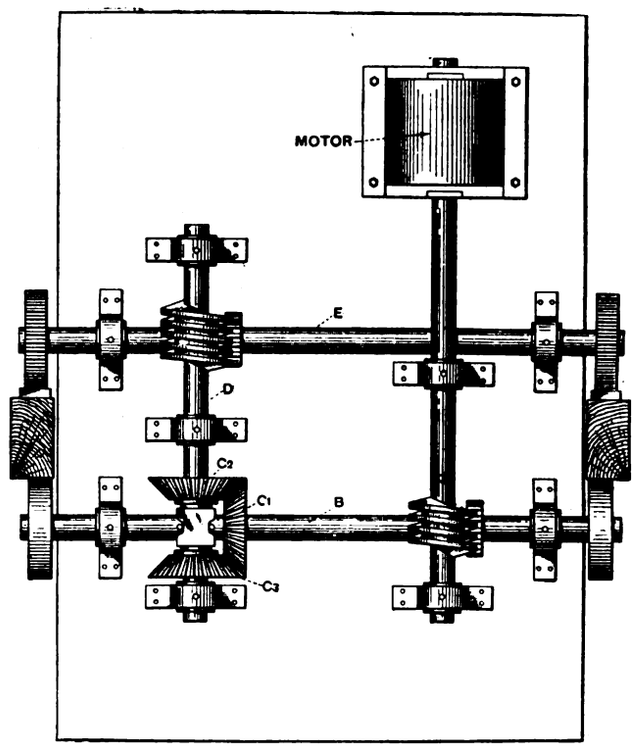

FIG. 1.

engineers do not more rigorously insist on the starting current of motors being kept down. It is purely a matter of what starting torque is required, and it can be brought as low as two-thirds of full load current or less by suitable arrangements. (*d*) A high frequency was adopted in the early days when it was common practice to instal small transformers in houses, with a view of keeping down the iron losses, the designers losing sight of the objection to a high frequency in view of motor working. It is well known that with a low frequency, a motor has the advantage of higher efficiency, higher power factor and smaller starting current.

The writer trusts that he has shown that the prejudice against the single-phase motor has its root not in any inherent defect in the motor but in the unsuitable nature of the appliances used. It will be seen that direct-current engineers would have equal cause to complain of their motors if they tolerated the defects in their systems which alternating-current engineers accept as inevitable. Imagine a D.C. engineer being first hampered with a 25 per cent. drop in his armature, then a drop in his feeders and distributors corresponding to the drop in the feeders, distributors and transformers (the latter wound for non-inductive loads only), allowing motors to be started from rest by means of a resistance so imperfect as to pass double or treble the full load current, and we should not be surprised at his complaining of the disturbance caused by his motors. Consider now the A.C. engineer with the added

* Paper read before the Municipal Electrical Association, at Huddersfield, June 21.

NOTE.—In this Paper the abbreviations D.C., A.C., S.P., refer to direct current, alternating current, and single phase respectively.

Digitized by Google

losses caused by a power-factor less than 90 and we see his difficulties in the face of unsuitable plant. The writer believes that it would be well worth while to go to the expense of re-winding alternators with these abnormal drops, to use only transformers rated on a power basis and in extreme cases to bring down the frequency to a reasonable value. Exception has been taken to the S.P. motor owing to its alleged inability to start against a load. This allegation is quite unfounded, as this condition can be complied with, but at the expense, of course, of starting current. It appears to the writer that this point has been laboured too much, as there are few cases in which a fast and loose pulley cannot be arranged. Moreover this defect has not prevented the enormous use of gas engines, which, so far from being able to start against a load, have actually to be pulled round by hand before they will start at all! Even in the case of lifts

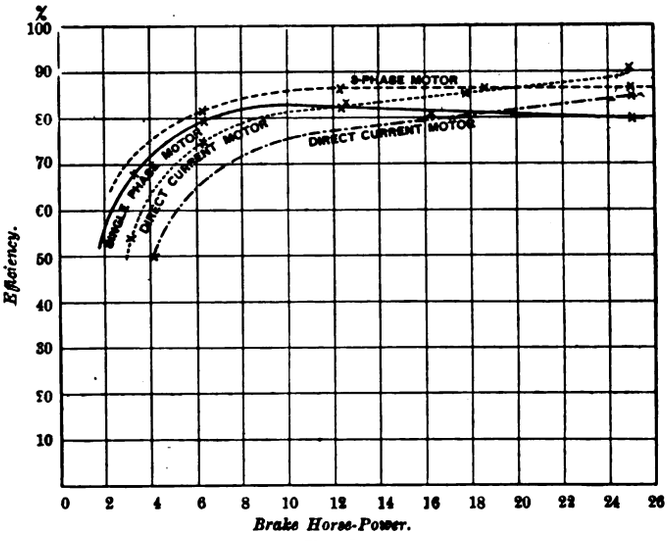

FIG. 2.

there is a wide sphere of utility for S.P. motors. The writer has a lift worked by a S.P. motor on the Derby mains which is perfectly satisfactory. Although the motor starts light, the lift is working at full speed within 7 sec. of the motor being switched on. A short description may be of interest. Fig. 1 is a plan of the cage; the motor and gearing are fixed on the top of the cage and move with it. The motor, a 4 B.H.P. Langdon-Davies, is switched on inside the cage and quickly runs up to speed, simply driving its own spindle and spindle B, and also the bevel wheels C_1, C_2, C_3; the two latter are at present loose on their spindle. The starting lever inside the cage when pulled over brings a friction cone to bear on the inner surface of the shoulder on bevel wheels C_2 and C_3. This throws shafts D and E into gear and causes the lift to rise or fall at will.

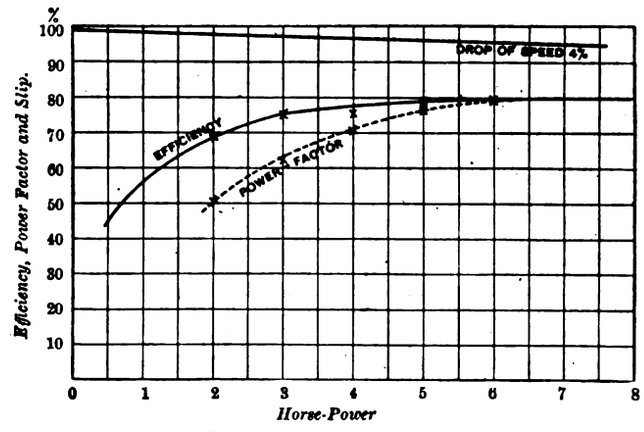

FIG. 3.—6 B.H.P. Single-Phase Motor.

The time necssary to start the lift, i.e., 7sec., is sufficiently small to justify the contention that the S.P. motor can be used for lift purposes in a great variety of cases.

A few notes as to what is actually being done on supply systems with S.P. motors may not be out of place. For purposes of comparison, it is a matter of interest to note what is being done in a city where the D.C. motor business is vigorously pushed. In Bradford the low charges and easy terms of hire have resulted in a considerable motor load being obtained. Up to the end of June, 1899, there were 307 motors connected to the mains, and the proportion of units sold for power to total units sold was about 17 per cent. It is doubtful if this result has been equalled in any other town in the country. It will perhaps be somewhat of a surprise to some members of the Association to find that on the Continent the above results have been far eclipsed by the use of S.P. motors. In the City of Frankfort, on March 31, 1899, there were single-phase motors of an aggregate of no less than 4,532 B.H.P. connected to the mains, while the proportion of power units sold to total units sold was no less than 58 per cent., the figures being, for power 1,851,268 units and for light 1.342,399 units, total 3,193,667 units sold. The largest motors are of 750 B.H.P., of which there are three. They are of the synchronous type and are coupled to D.C. generators, and are used for driving the trams. With the exception of these all the motors are of the induction type, the largest of which are of 90 B.H.P. The larger motors are run from separate transformers fed from the nearest feeders, while the smaller sizes are taken direct from the low-tension network, while the steadiness of the light leaves nothing to be desired. The generating sets are as follows: Two of 1,500 I.H.P. and four of 750 I.H.P. The frequency is 45 periods and the armature drop 6 per cent. The charges for power are equivalent to 2d. per unit with discounts up to 25 per cent. The Corporation of Derby have within the last few months commenced letting out S.P. motors on hire with gratifying results. At the present time motors equivalent to about 200 B.H.P. have been connected, of various sizes up to 30 B.H.P., and the units sold for power during the year have amounted to about 12 per cent. of the total units sold. The charges vary from 3d. to 1d. per unit according to the length of time the motor is used.

A few words may now be said on the chief characteristics of the modern S.P. motor. The only practical motors on the market are of the synchronous and the induction type. The sychronous motor requires its field to be excited by a direct current. It is not usually self-starting, and this defect precludes its adoption for any but large sizes. It has an extremely high efficiency and power factor, and it runs at a synchronous speed. The induction motor, which is almost exclusively used, has been greatly improved in recent years. A few years ago the maximum efficiency was not expected to be more than 60 per cent. to 65 per cent. with a power factor of about the same value, while the starting current, even when the motor started light, was often two or three times the full current. Thanks, however, to the good work of Tesla, Brown, Langdon-Davies, and others, very marked improvements have been effected within the last two or three years.

The following table gives a good idea of the efficiencies of modern single-phase motors, as compared with direct-current and three-phase motors. All the tests are made from motors actually at work, the S.P. motors being on the Derby mains. The motors were all made by leading firms, and though the figures do not necessarily represent the highest attainable results, they are a fair sample of good modern practice :—

Type of motor.	Brakes, H.P.	Efficiency. Full load.	Half load.	Quarter load.	Eighth load.
		Per cent.	Per cent.	Per cent.	Per cent.
Direct current	4	78	68	53	...
Ditto	3	84	77	59	35
Single phase	2	78	76	62	...
Ditto	6	80	76	62	46
Three phase	10	83·5	82	72	55
Single phase	12	75	78	68	54
Ditto	25	80	83	80	68
Three phase	25	87	86	82	72
Direct current	25	91	83	75	54
Ditto	25	86	78	66	...

Diagram (2) shows the efficiencies of the above-mentioned four motors of 25 B.H.P. plotted together for ease of comparison. The interesting fact to be noted in both the diagram and the tables is that, while the efficiency at full load in the D.C. motors is the higher, the S.P. motors have the advantage at low loads, and it is probable that where the work to be done by a motor varies considerably, as, for instance, in a machine shop, the average efficiency of the S.P. motor is quite as high as, if not higher than, in the D.C. motor. Diagram (3) of the power factor and efficiency of the above 6 H.P. motor shows that while there is still room for considerable improvement in the power factors, the modern motors exhibits considerable advancement during recent years.

In conclusion, the writer would urge that while the S.P. motor still leaves much to be desired in the matter of power factor, starting current, starting torque, and facility of running at variable speeds, yet the absence of commutators with their attendant troubles giving such simplicity in working, together with the high average efficiency, render it eminently suitable for general distribution work. As is shown in the Table the polyphase motor outstrips both its competitors in point of efficiency. The writer would suggest that should a transformer or other appliance be placed on the market which without moving parts would convert a single-phase into a polyphase current, in the same manner that a two-phase can be converted into a three-phase current, in this direction may lie the solu-

Digitized by Google

tion of the motor problem. With the increase in size of our stations, the engineers of direct-current works are more and more realising the advantages of alternating currents for generation and transmission. The improvements in modern A.C. motors have gone a long way to lessen the force of the objection to alternating currents for distribution purposes as well, and the writer's experience justifies him in the opinion that the A.C. motor (either single or polyphase) is quite capable of satisfying all ordinary demands for power from the mains of public supply undertakings.

LIGHT RAILWAY SCHEMES.

In our issue of June 15th we gave a list of the applications lodged with the Light Railway Commissioners during the month of May, and we are now able to give further particulars of the projects in which electric traction is specified. Though the total number of applications shows a considerable falling off compared with November and May of 1899 (when the numbers were 43 and 40 respectively), the proportion of electrical projects is maintained. On the present occasion the promoters of 17 of the schemes propose to employ electric traction, the figures for the two previous occasions being 32 and 21 respectively. Five of the present applications are for powers to make extensions of light (electric) railways already authorised. The Bath and Swansea schemes have been revived. In the first case there is a joint application by the Bath Corporation and a private syndicate, and we trust it may meet with a better fate than the two rival applications did last year. The Swansea Corporation seek to obtain the powers which the Swansea Tramways Co. unsuccessfully applied for in 1899. The statistics of the total applications, together with the proportion of electrical schemes which have been lodged with the Commissioners since the passing of the light Railways Act will be of interest, and are as follows:—

	1900.	1899.		1898.		1897.		1896.
	May.	Nov.	May.	Nov.	May.	Nov.	May.	Nov.
Total applications	24	43	40	54	35	30	28	28
Electric schemes.....	17	32	21	32	18	16	10	14

These figures would seem to indicate that, notwithstanding the absence of any onerous purchase clause, promoters of light railway and tramway schemes are becoming less inclined to adopt procedure under the Light Railways Act, as, unless an agreement has been previously arrived at with the road authorities, the application has small chance of being approved by the Commissioners. In addition, the Commissioners have no power to authorise the compulsory acquisition of land, and in all cases there is an appeal to the Board of Trade against their order—a right which is freely exercised by the opposing municipalities and railway companies. As, however, the Light Railways Act is only an experimental one, and will shortly expire, Parliament may be disposed to consider the advisability of amending and improving the procedure in this and other respects.

CORRESPONDENCE.

STELJES' TYPEWRITING TELEGRAPH.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of June 29th you were good enough to give a description of the above system of telegraphy (page 359) and as reference is made to the speed of the working of this instrument, which as therein given may be somewhat prejudicial to the system, I feel sure you will allow me to say that the rate of speed of the transmission of a message by an unskilled operator varies from 14 to 18 words per minute. An enterprising office boy was ambitious to try his prowess in this line and accomplished 18 words per minute, and other inexperienced workers came out at from 14 to 18 words per minute. With very little practice 25 is easily obtained.

The alternations of this instrument are rapid. The Wheatstone transmitter we use is of a modified form, and of a pattern I understand the Post Office is now adopting.—Yours, &c.,

C. E. SPAGNOLETTI.

Ealing, W., July 3.

THE TRAMWAYS AND LIGHT RAILWAYS EXHIBITION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Referring to the paragraph in your current issue dealing with our material at the above exhibition, we beg leave to point out that your description of the manner in which our single-phase (Heyland) motors are started is incorrect. These motors do not employ a choking coil at starting, as stated, the starting coils and running coils being switched in parallel directly across the line, there being no auxiliary apparatus whatever. Under these circumstances the motors for 40, 50 and 60 cycle circuits start with full load torque, with a current consumption not exceeding twice the full load current.

We are sorry that your representative, when visiting our stand, apparently missed seeing the specialities in traction work we are showing. We refer more particularly to our light railway truck, standard car controller, scotch for hilly districts, new hand brake, &c., which we venture to think are the chief novelties in the Exhibition.—Yours &c.,

WITTING BROS., LTD. (Electricite et Hydraulique),
S. C. WITTING, Managing Director.

49, Cannon street, London, E.C., July 4.

PARLIAMENTARY INTELLIGENCE.

(*Continued from page 404*)

THE ELECTRIC POWER BILLS.

The House of Commons Committee on the Electric Power bills held another sitting on Tuesday, Sir J. Kitson presiding.

The CHAIRMAN said that before any further progress had been made the Committee would make a declaration. Subsequently he said: The statement I have to make now is an expansion of the declaration of the Committee which has already been given to you on the South Wales bill. It is as follows:—

1. The company to be authorised to supply electrical energy for power purposes anywhere within the area of supply subject to the consent of the local authority in certain cases as set out below.
2. The company to have no general lighting powers, *i.e.*, distribution to ordinary consumers within the area, except in pursuance of a provisional order obtained in the ordinary way.
3. Where a local authority is now authorised to supply electricity within the area their consent is to be required for the supply of electricity by the company, the Board of Trade to be empowered to override the refusal of the local authority to give consent if the authority are not prepared to provide the requisite supply on reasonable terms and within a reasonable time.
4. Any local authority who hereafter gets statutory powers for supplying electricity within the area to have in ordinary cases the option of taking over the company's supply in its local area on terms to be laid down by the provisional order or act by which the statutory powers are given.
5. A company having statutory powers to be in the same position as a local authority now having statutory powers; a company to whom powers are hereafter granted to be placed in the same position as a local authority to whom statutory powers are hereafter granted.

That is the decision of the Committee, and it is suggested that the Government draughtsman, Mr. Thring, should meet the agents and go through the clauses.

The Agent for the Lancashire bill said he did not think there was anything in the Committee's declaration which would apply to the Lancashire bill.

The CHAIRMAN: We have made no declaration on the Lancashire bill because it is not affected by these provisions.

On Wednesday considerable discussion took place respecting the wording of a clause drafted by the Board of Trade for the purpose of carrying out the Committee's declarations on the South Wales Bill. Eventually the clause was adopted by the Committee in the following form:—

The powers of the company for the supply of electricity under this act shall be subject to the following provisions:—

1. Electricity shall be supplied under this act only (*a*) for supply in bulk to authorised distributors; and (*b*) for the purpose of providing power and for the lighting by any person to whom it is so supplied for power of any premises in any part of which the power is utilized.
2. Electricity shall not be supplied under this act by the company in any area being at the passing of this act the area of supply of any authorised distributors, except with the consent of those distributors, but the consent shall not be unreasonably withheld. If any question arises whether that consent is unreasonably withheld or not, that question shall be determined by the Board of Trade. The consent shall be deemed to be unreasonably withheld if the authorised distributors are not willing and in a position to give the requisite supply upon reasonable terms and within a reasonable time, and in considering what are reasonable terms and what is a reasonable time, the Board of Trade shall, amongst other things, have regard to the terms upon which, and the time within which the company are willing and in a position to give the supply.
3. If at any time after the passing of this act any local authority or company become authorised distributors in any area within the area of supply under this act, the company shall be subject to any provisions which may be made by the act or provisional order under which the distributors became authorised as to the taking over of any supply then given to the company for use exclusively within the area of supply of the distributors.
4. Nothing herein contained shall prevent a company from applying for provisional orders under the Electric Lighting Acts of 1882 and 1888.
5. Nothing in this section shall authorise a company to supply electricity for lighting, other than the lighting specially mentioned in this section.

In this section the expression "authorised distributors" means any local authority, company, body, or person authorised by Act of Parliament, or provisional order confirmed by Parliament to supply electricity within the area of supply.

Yesterday, Mr. H. LLOYD, on behalf of Barry Council, asked the Committee to re-consider sub-section 2 of the clause drafted (as above), respecting the conditions under which the supply of electricity was to be given, and to insert a proviso that distributing mains should not be laid by the company in the area of supply of any authorised distributors except with the consent of those distributors.

The Committee declined to insert such a proviso, whereon Mr. Lloyd said his clients regarded the question as one of principle, and therefore he should take no further part in the proceedings—indicating that the bill would be fought in the House of Lords.

Mr. FITZGERALD, representing local authorities in the Rhondda Valley, brought up a sliding scale and proposed its insertion. After some discussion,

The CHAIRMAN said the Committee had decided that the dividend payable by the company should be limited to 8 per cent. instead of to 10 per cent. as proposed in the bill, and that there should be a clause giving the Board of Trade power of revision after 10 years.

The Durham County Bill was then considered, and Mr. BALFOUR BROWNE, Q.C., on behalf of the promoters, asked for powers of supply within the authorised area of supply of other companies.

The Committee reserved their consideration on this point.

The question of the application to the Durham and Lancashire bills of the limitation of dividends to 8 per cent. was next dealt with.

Mr. MOON, for the promoters of the Durham bill, said it was a matter for serious consideration whether the promoters would accept the measure with a dividend limited to 8 per cent.

Mr. RAM, Q.C., for the South Wales promoters, remarked that his clients believed that it would be absolutely impossible to get money if they were to be restricted to a hard and fast dividend of 8 per cent. without a sliding scale. There would be no inducement, if such a dividend were fixed, to lower the price to consumers.

The Committee, recognising the importance of the question, decided to hear arguments on the question of dividend, but declined to hear evidence. Counsel having spoken on the point, the Committee deliberated.

The CHAIRMAN said: The Committee adhere to the decision they have come to, that the standard dividend should be fixed at 8 per cent., but having heard the arguments of counsel, they are willing that a sliding scale should be adopted, the principle of the sliding scale being 5 per cent. discount on the amount charged on the raising of the dividend by 1 per cent. The Lancashire and Durham schedules as amended will be the standard price for Durham and Lancashire. The standard price for South Wales will be 2½d., the sliding scale and the standard price charged being subject to revision in 10 years.

The Committee then adjourned till to-day (Friday).

SHANNON WATER AND ELECTRIC POWER BILL.

The Select Committee of the House of Commons, presided over by Sir Frederick Godson, on Tuesday commenced the consideration of this bill, by which it is sought to incorporate a company with capital powers of £300,000, and borrowing powers of £150,000, with power to use the water of the Shannon for generating electricity to be sold in bulk to the city of Limerick and other local authorities in the county of Clare.

Mr. BUSHE, Q.C., for the bill, quoted the remarks of Sir James Kitson, from whose Committee the present bill had been transferred, with reference to the provision of electric power. Sir James said he felt that the value of electrical energy had been amply demonstrated. Its importance to industries was admitted, and the Committee were accordingly advised that it was to the public advantage to facilitate measures for the supply of electrical energy to all consumers who wished to avail themselves of the economy and efficiency of electric power. Sir J. Kitson's Committee also accepted the recommendations contained in the report of the joint committee of 1898, especially as regarded that part providing compulsory powers for acquiring lands for generating stations, easements, &c. The manufacturers of Ireland were in a torpid state, and so long as they depended on coal as a motive power they could not flourish. The company asking to be incorporated by the Bill desired to use the water power of the river Shannon for the purpose of generating electric energy in order to serve Limerick and the district round for some 30 miles. The area of the water proposed to be utilised was 30,000 acres, with an average depth of 30ft, and consisted of the drainage of some 4,000 or 5,000 sq. miles. The average flow of the Shannon at Killaloe was about 330,000 cubic ft. per minute. In regard to the works proposed by the company, there was an already existing canal leaving the Shannon about 6 miles from Killaloe and running to the south. They proposed at that point to make an intake nearly parallel with that canal and to return the water to the river lower down. They proposed to have their generating centre at Cloonlara, some 2½ miles from the intake. At that place there was a fall in the river of 40ft., and there they proposed to place turbines capable of producing energy up to 8,000 H.P. The works, however, would be capable of development. It was estimated that 5,000 H.P. would at first be necessary. From Cloonlara down to Plassy Lock a race would be constructed to carry the water back to the Shannon; the only effect, therefore, upon the river would be that water would be borrowed from it and afterwards returned to it some miles lower down the stream. The scheme had the unanimous support of the local authorities concerned. In order to meet the case of droughts, it had been agreed with the Board of Works of Ireland, who were the Navigation Commissioners of the Shannon, that a minimum fixed flow of water should be left in the river. That minimum had been fixed at 90,000 cubic ft. per minute of water going down the river, and when the flow fell to that limit the intakes of the company would remain closed. The Limerick Corporation were the electric lighting authority for their city, and although they desired to save their rights in regard to electric lighting and water they did not see their way to generating electrical energy themselves, but rather looked to the promoters as the wholesale dealers who would bring the electricity to the city in bulk. The Corporation, therefore, were watching their interests before the Committee in a friendly spirit.

Mr. TAYLOR, Q.C., for Limerick Corporation, said the Corporation only desired protection for the city water works and electric lighting; beyond that they would not trouble the Committee.

Mr. FRASER, C.E., engineer to the project, said he had carried out works to the value of £2,000,000 in Ireland. The present proposal was to use the waters of the Shannon, now running to waste, for the purpose of generating electric energy for supplying Limerick and places around. The proposed works consisted of two parts, the first being simply a great canal cut down to Cloonlara, where the power station would be situated, and there, over a distance of about 2½ miles, they got a fall of 40ft. The second part of the works was a gigantic tail race, the water being taken from the river above, and returned lower down, there being no interference with the river whatever. The scheme merely meant a big cutting, the bottom of which was concrete. The electric power

Digitized by Google

would be transmitted to Limerick 4 miles or 5 miles away, and to various other points, as the small towns in the neighbourhood were most anxious to get both light and power—light because gas cost them 6s. 6s. per 1,000 cubic ft., and power because it would enable them to retrieve their industrial position. The radius of supply would be 30 miles. In Italy, where there was little coal, they were rapidly utilising their water powers for the production of electricity, and so Italy was becoming a manufacturing country. The experience in Italy, Switzerland, and in the neighbourhood of the Niagara Falls, had shown that electricity as a motive power for machinery conduced both to an economy of money and space. The Corporation of Limerick had granted a concession for some 7 miles of electric tramways and the Tramways Company would take their motive power from the promoters. The cost of the works proposed would be great (£300,000) in the first instance, but after that only a small sum would be necessary for upkeep. The prices to be charged were the same as those adopted in the three great power bills passed during the present session, namely, for any quantity not exceeding 200 hours of supply at the maximum power, 5d. per unit; not exceeding 400 hours, 3d. per unit; above that amount 2d. per unit. When the river fell below the minimum flow steam power would be used to produce current.

Mr. J. CLARKE, an American electrician, gave evidence in support of the scheme. He said that these schemes of working with auxiliary steam power were highly successful in America.

Mr. RICHARD HAZARD, C.E., joint engineer to the scheme, gave corroborative evidence, and evidence having been taken to show that no injury would be done to the fisheries on the Shannon, the promoters case was closed.

Mr. BALFOUR BROWNE, Q.C., for the Limerick Fishery District Conservators, said he would be able to show that great damage would be done to the riparian proprietors by the proposals of the bill, as they would be deprived of the water necessary for the salmon fisheries in times of flood, and no compensation water would be supplied in times of drought. The Shannon salmon fisheries were worth £40,000 a year, and they ought not to be injured without adequate compensation. Counsel quoted statistics that show that according to the rainfall of previous years the promoters would not be able to obtain on a considerable number of days in each year the power they proposed to supply. Under the bill the promoters would be unable to carry out the scheme before they had come to Parliament for powers to construct the weir necessary on the Shannon, and he, therefore, asked the Committee to reject what was really a piecemeal scheme.

Mr. BUSHE, Q.C., said that sec. 12 of the Waterworks Clauses Act of 1847 which was included in the bill, and which dealt with the case of persons whose water was diverted, would give to the riparian owners all possible protection in regard to compensation for damage to their fisheries.

Mr. MACASSEY said the case for the fisheries was that they would be, if not destroyed, so seriously injured as to be worth nothing if the works under the bill were carried out. They, therefore, asked for the rejection of the measure.

The CHAIRMAN said, if anything stronger than the clause in the bill was asked for, the Committee were willing to consider the matter, and, if necessary, fix the amount beyond which compensation should not go. In regard to finance it was so much a matter for the promoters that, if the Committee were given, as they had been, a fair justification for considering that the £300,000 necessary would be raised, they would not go into the question as to whether £30,000 or so more might be required. No company ever did what it said it would do with its first capital. As to whether the company would have to come to Parliament again for authorisation to construct a weir, that was not before the Committee.

Mr. BALFOUR BROWNE said if the Committee were inclined to insert a provision for money compensation he would retire. He had yet two chances against the proposers of the bill—one in the Lords and the other when the bill authorising the weir came before Parliament—and his clients were meanwhile protected. The promoters could not touch a drop of water in the Shannon until the other bill was passed.

The CHAIRMAN: Supposing, Mr. Browne, those whom you represent wished to get money compensation afterwards, would the clause in the bill protect them? Will you produce a clause?—No, I will not. Much would depend on the character of the weir proposed to be constructed. It might do much or little damage. If the Committee thought that money compensation would meet his clients' case, despite the large body of evidence he could produce to the contrary, he would prefer to go to a tribunal that would hear him. The Committee had sufficiently indicated its view, and with the concurrence of his clients he proposed not to take any further part in connection with the bill.

Counsel then withdrew, reserving their opposition for the Upper House.

On behalf of the Corporation of Limerick, Mr. TAYLOR, Q.C., intimated that clauses having been agreed between parties, they were now supporters of the bill.

The Committee passed the preamble, and the bill was ordered to be reported as amended.

DUBLIN ELECTRIC LIGHTING BILL.

In the House of Commons on Monday, on the order for the third reading of this bill, Mr. CAREW moved that it be read a third time that day three months. The measure, he said, was against the tendency of the age, which was that undertakings for the supply of electric lighting should be in the hands of local authorities.

Mr. FIELD having seconded the motion,

Mr. A. BROWN, as chairman of the Committee appointed by the House of Commons which passed the bill, explained the reasons which had influenced the Committee in their decision. The Dublin Corporation had done little or nothing to carry out the powers it possessed under its provisional order to supply electrical energy, and the Committee therefore considered that the application of a private company asking to be authorised to give the city of Dublin and some of the out-townships a supply of electric light should be granted. The opponents of the present bill had taken the most unusual course of opposing it on the report and on the present stage. He looked to the House to uphold the decision of the Committee.

Mr. T. W. RUSSELL supported the motion. He said the Corporation of Dublin had failed to give a proper supply of electric light, only because they had been occupied with great schemes of main drainage and artisans' dwellings. The Corporation had much to contend against, as Dublin was a city in which the very poor were a great factor. As a citizen and ratepayer of Dublin he saw that the city's revenue would have to be spent in a few years' time in buying out the proposed electric lighting company.

Mr. RITCHIE could not bring himself to believe that the Corporation of Dublin could not obtain money to carry out their obligations as regards electric lighting as well as perform their ordinary duties as a municipal body. From the consumers' point of view there was no doubt the bill should be passed by that House, and its Committee's decision thereby upheld.

Mr. BLAKE held that the passing of the bill would be a positive calamity to Dublin and a distinct infringement of the rights of municipal corporations generally. As to the allegation of incapacity on the part of the Corporation, if it was Dublin that erred it was Dublin that suffered, and if it kept going wrong the ratepayers would most assuredly make the municipal authority do its duty. The Corporation had now obtained the necessary moneys and were ready to proceed.

Mr. T. M. HEALY said a great injustice would be done to the ratepayers of Dublin if the bill were rejected. For ten years the Dublin Corporation had possessed full statutory powers to provide an efficient system of electric lighting; had spent £100,000; and yet out of the 250,000 people in their area, only 250 were supplied with electric current. He pleaded for free trade in electricity supply. The third reading was ultimately lost by 6 votes—174 to 168.

MARYLEBONE (LONDON) PROVISIONAL LIGHTING ORDER.

In the House of Commons on Tuesday, on the motion for the second reading of the Electric Lighting Provisional Order (No. 2.) Bill, Capt. NORTON moved that the bill be read a second time that day three months. He said that he had taken that step at the special request of the Marylebone Vestry and other local authorities. This showed that the question was no narrow issue between Marylebone parish and an electric lighting company, but a matter that affected important parishes in the county of London. The bill was inopportune, and if it were passed the new Marylebone Council would either have to give up all idea of undertaking the electric lighting of their area or be driven to buy out two companies at enormous cost. In 1889 the Marylebone Vestry consented to the Metropolitan Electric Supply Co. providing the parish with electric current. The demand for current for lighting became so great that the company was unable to meet it, and thus did not give complete satisfaction. Harassed by complaints of inhabitants the Vestry made two unsuccessful attempts to obtain electric lighting powers. In view of the fact that they were to be soon constituted a borough council they had decided to apply again for an order, and they had entered into a provisional agreement with the Metropolitan Company for the purchase of so much of the undertaking of that company as lay within their area. Now the Marylebone Electric Lighting Co., which was identical with the St. James's & Pall Mall Electric Light Co.—one of the best electric lighting companies in London, he admitted—was trying, by promoting the present bill, to obtain a footing in Marylebone. He thought it would be admitted that to allow a new company to come into the parish would greatly handicap the new Borough Council at the beginning of their career.

Gen. LAURIE having seconded the motion,

Mr. RITCHIE (President of the Board of Trade) explained the position in regard to the present bill. He said that the supply of electric current in Marylebone had been extremely bad for some years past and had been greatly complained of. It was therefore necessary that something should be done to remedy that state of things. Two years ago the Marylebone Vestry applied for a provisional order to enable them to give a competitive supply. The House of Commons agreed to read the bill a second time, but it was rejected in Committee. Subsequently a deputation waited on the Board of Trade to complain of the quality of the electric light supplied by the Metropolitan Company. The Board was practically powerless, and the only remedy for a grievance of that kind was competition. In order to meet the difficulty he now proposed an instruction to the Committee (if the bill was read a second time) that it should consider the expediency of inserting a clause in the order providing that the order should not come into operation until a date to be decided upon by the Committee, and should not then come into operation if the undertaking authorised by the Metropolitan Electric Supply Co. (West London Order, 1889), should have been purchased by the Marylebone Vestry or its successors. He hoped the House would send the bill to a Committee to consider all the questions which would come before it.

After Mr. CRIPPS had spoken in opposition and Mr. LYTTELTON in support of the bill, the second reading was lost by 28 votes—147 to 119.

NORTH METROPOLITAN ELECTRIC SUPPLY BILL.

The Committee of the House of Commons on the North Metropolitan Electric Supply Bill, presided over by Mr. A. H. Brown, met again yesterday, when it was expected they would give their decision as to the conditions under which the powers conferred by the bill should be exercised; but after sitting for an hour with closed doors, the chairman proceeded to the room in which the Special Committee on Electric Power schemes is sitting, and, after conferring with Sir James Kitson, announced that the decision in the North Metropolitan case would not be given until Monday.

Digitized by Google

ELECTRIC LIGHTING ORDERS.

A Select Committee of the House of Commons, presided over by Sir. F. Godson, considered the bill to confirm the Electric Lighting Provisional Orders (No. 10) granted by the Board of Trade to Battersea, Limehouse, Mile End Old Town, and St. George's-in-the-East. The Battersea order was not opposed.

Mr. Shiress Will, Q.C., and Mr. John M. Stone appeared for St. George's-in-the-East; Mr. Claude Baggallay, Q.C., and Mr. Lambert for Mile End Old Town; and Mr. Worsley Taylor, Q.C., and Mr. Ackworth for Limehouse. All three orders were opposed by the County of London & Brush Provincial Electric Lighting Co., who were represented by Mr. Pember, Q.C., Mr. E. Moon, and Mr. Shaw.

Mr. SHIRESS WILL for the St. George's-in-the-East order, said the points were substantially the same in all three cases. These places, in conjunction with Whitechapel, were about to be made into one municipality, under the Government of London Act of last year. Whitechapel already had the electric supply in its own hands, and the other three local bodies applied to join so that the supply should be in the hands of the new municipality. There was at present a company, the County of London & Brush Provincial Co., authorised to supply within the area, who were opposing the orders. But the fact was that that company had done nothing towards supplying any electricity under their order; and shortly after the act forming the new municipality was passed a meeting of delegates from the four districts was held and it was determined to apply for provisional orders. In the result the Board of Trade made the orders which the Committee were now asked to confirm. The scheme was that the whole of the four undertakings shall become one undertaking and be in one hand. The works of the Whitechapel Vestry, which were sanctioned under a provisional order of 1892, were capable of being made sufficient for all four places, and they were thus able to supply energy more cheaply and economically than if each district had been obliged to make a separate generating station. As to the position of the County of London Company they obtained a provisional order in 1897, but nothing was done till 1899, when the local authority received notice that the company intended to proceed. They said this was because they had received obstruction from the local authority. But the reason was very different. The company had a generating station in the north of London (at St. Luke's, Cerkenwell) and instead of putting in a generating station at the East End they wished to supply from St. Luke's station. Last year they tried to obtain powers to lay mains from this generating station to the East End. That bill was rejected, and again this year they had introduced a bill for the same purpose and again failed. Their object was, by agreement with the Regent's Canal Co., to carry a main from St. Luke's down the banks of the canal to the edge of Mile End Old Town and so escape all parliamentary and local control. He ventured to submit that as a general principle where a local authority gave consent to a company obtaining powers to light the district, where that company did its duty Parliament would not be disposed to allow the local authority to compete. But in this case the company had not done its duty—it had not laid a yard of mains or turned a spade of earth, and had not spent any capital at all. The policy of the electric lighting acts was to enable the local authority within some limited period to purchase the undertakings of the companies; but in this case the authority would only be able to buy the mains and lines and posts in their own district, and would have no power to purchase the generating station at St. Luke's.

Mr. HORATIO THOMPSON, vestry clerk of St. George's-in-the-East, said the parish had a population of 47,500, and an area of 244 acres, a considerable portion being occupied by the London Docks. In 1896 they were approached by the County of London Company, and gave their consent to the company's applying for a provisional order, but the first notice of their intention to commence work was in September, 1899, two years after their powers commenced.

Mr. W. C. PARSONS TAPPER, resident electrical engineer of the Whitechapel District Electrical Department, said Whitechapel had got a provisional order of their own, and had supplied electricity for about six months. The demand was rapidly increasing, and they were already extending their works. These works were capable of extension, and if necessary, when the new borough was formed, they could put another station at the river side. There was a growing demand for motive power. The average price for current was 3d. per unit, both for lighting and power; but during the six summer months they charged at the rate of 1d. per unit. They had already laid 7 miles of mains at Whitechapel. The installation was made with a view of supplying Whitechapel only, but they had a large area on the present site for extensions. Their system was the low-pressure direct-current. By this system there was a considerable loss in transmission in large areas.

Mr. PEMBER, in reply to the Chairman, said the average charge per unit of the County of London Company was 4d. or 4½d.; it, in fact, varied from 7d. down to 3d.

The CHAIRMAN suggested that if necessary the promoters could by consent erect further works on the river.

Mr. PEMBER said in that case they would be liable to actions for nuisance.

Mr. BAGGALLAY remarked that in all cases of provisional orders for supplying electricity provision was inserted that the undertaking should not be exonerated from any action or proceedings for nuisance. That provision was in each of the orders and in the general act of last year.

Mr. MOON said the orders had it, but the acts had not. If they got compulsory powers by an act they would only be liable if their works were carried on negligently. That was the distinction which had been made, following the report of the Joint Committee of both Houses.

Major CARDEW said having regard to the formation of the new borough he considered Stepney would make a very fair area for an electric supply and it ought to be successful. He had inspected the works at Whitechapel. They had a very considerable area on which they had started the construction of a station which could be extended to contain 15,000 H.P., which would serve for a time the whole district. As soon as that station was full up they could secure another site by the river, where they would be able to get coal and cart away the dust with greater facility and get water for condensation. For the kind of motive power used in the district, he considered the continuous-current system which was given from the Whitechapel station would be more suitable than the alternating current from the Clerkenwell station. He agreed that up to moderate limits the larger the station and the more business you could do from it, the cheaper would be the rate at which you could supply electric current.

This was all the evidence for the promoters of the St. George's order, and the Committee agreed to reserve their decision and to hear the opposition at the end of the promoters' case for the three orders, which must stand or fall together.

Mr. MILLNER JUTSUM, vestry clerk of Mile End Old Town, examined by Mr. Claude Baggallay, for Mile End, said the City of London Company had asked the consent of the Vestry to the provisional order, but that consent had been refused.

Mr. J. M. KNIGHT, surveyor and engineer, stated that in the negotiations with the company in 1897 it was distinctly contemplated that the generating station should be in the district they proposed to supply.

Mr. BAGGALLAY said if the company had intended in 1897 to supply electricity from St. Luke's station that should have been put into their order. It was not unfair that the local authorities should seek to supply themselves, because the company had never done a stroke of work in the district, and if there should be competition it would be because the company with their eyes open came in and established works in competition with the local authority.

Mr. S. G. RATCLIFFE, clerk to the Limehouse Board of Works (speaking to the Limehouse order), said the Board were strongly in favour of the order promoted.

Mr. C. P. SPARKES, chief engineer of the County of London Company, in support of the company's petition, detailed the steps the company had taken to get a main into the district. In consequence of the opposition of the local authorities they had arranged to carry it along the Regent's canal. The provision they had made would be sufficient to supply in the first instance 500kw. and at a later period 1,500kw., which was amply sufficient for the immediate wants of the district. They had capacity for the needs of the district at their City-road station, which was very favourably situated. Their price began at 7½d. and went down to 3d. for lighting, and for power purposes 2½d. per unit. If they could secure a considerable demand for power, they could reduce very largely the cost of current for lighting. Their rates compared favourably with those in the London district. The lowest rate in London at present was 2½d., but at Manchester and Edinburgh, where there was a large demand for current for power, the price had been reduced to 1½d.

Mr. SYDNEY MORSE gave the history of the company and its various orders. The reason the company had never supplied in the East End district was that they desired to save the expense of providing a generating station, and the local authorities had declined to allow them to put a main from St. Luke's to the East End.

Mr. MOON then addressed the Committee, contending that unless the company could be proved to have neglected its duty, Parliament should not allow the competition of a local authority. Within four months the company could supply the district. They had their plans sanctioned, and had spare capacity at their generating station.

The CHAIRMAN said the Committee would confirm all the orders. The preamble of the bill was then considered and agreed to, and the bill was ordered to be reported.

EAST HAM TRAMWAYS BILL.

On June 29 the Select Committee of the House of Lords, presided over by the Duke of Northumberland, commenced consideration of the bill to confirm the provisional order obtained by the East Ham District Council with regard to tramways.

Mr. HUTCHINSON said the bill would enable the East Ham Council to construct certain tramways within their district. The only opposition arose from the Great Eastern Railway Co. with regard to the crossing of their line on the level by the tramways, which were to be worked by electricity. The railway company alleged that the crossing would be attended with serious danger to the safe working of their line, and asked that it should not be allowed. The Council, on the contrary, held that there was no danger in the crossing, and that it should be allowed.

Mr. CAMPBELL, engineer and surveyor to the Council, gave evidence as to the great need for this line. With regard to the level crossing he pointed out that the trains passed along that line at intervals of about two hours, and the Council held that if the present tramway was authorised the danger attaching to the crossing would not be added to. The trams would run about every 20 minutes, and both trams and trains would run at less frequent intervals as the district further developed.

Mr. STEPHEN SELLON, consulting railway engineer to the Council, drew a number of distinctions between this case and that of Hull. At Hull the crossing was over a line used for goods only, whereas here the line was used for passenger traffic. On a passenger line there was much more protection by signalling on the block system than on a goods line. At the East Ham crossing, therefore, the gates would be under the control of the signalman, and no tram would be able to enter them unless the signal was given that the line was clear. Then, whereas, at Hull there were some 260 trains passing daily (that was a few trains magnified into 260 by shunting backwards and forwards), here there was no shunting, and only seven or eight trains daily. In Hull a three-minute service was talked of; here it would be every 15 minutes or 20 minutes. Further, in the case of Hull, the line was double; in the present case the line would be single.

Digitized by Google

Mr. GOODAY, the general manager of the Great Eastern Railway Co, said they objected to the crossing of their line by the tramway on the level. The district was rapidly developing, and the company might have to run a quarter-hour service and a service of night trains. For the reasons stated in the Hull case he held that the crossing was objectionable, and also because of the danger and interference with the regularity of the trains which it might involve. He agreed that there was more danger in irregular working of goods traffic, but it was more serious if accidents occurred on a passenger line. There was, he also agreed, more danger with a double than with a single line of trams.

Mr. JOHN WILSON, engineer of the Great Eastern Railway Co., said a level crossing would always be a source of danger and trouble, especially when, as was likely in this case, the railway line would have to be doubled. From an engineering point of view, there was great difficulty in a light railway, as this was, crossing a heavy railway line, because you could not weld a 25lb. rail up to an 85lb. rail. It would be impracticable to cut a groove in the large rail to take the smaller rail. He objected to a light rail, no matter what it was to carry, over a level crossing.

Mr. HUTCHINSON, in answer to the chairman, said the order provided that the level crossing should only be made with the sanction, in writing, of the Board of Trade. He would prefer to have the provision as to the sanction of the Board of Trade struck out.

The Committee eventually passed the order as it stood, with the Board of Trade provision.

HAMILTON, MOTHERWELL, AND WISHAW TRAMWAYS BILL.

This bill was heard before the Select Committee of the House of Lords, presided over by Lord Ribblesdale, on June 22. The promoters of the bill are the British Thomson-Houston Co. The only opponents were the two railway companies in the district—the Caledonian and the North British.

Mr. BALFOUR BROWNE, Q.C., for the promoters, said the tramways commenced at Blantyre, passing through Hamilton and Motherwell to the centre of Wishaw. The length of line was 8½ miles—5¼ double and 3¼ single line. The tramway would be worked by electricity on the overhead system. The district was a poplous one, and there were from end to end of the line collieries and manufactories. A branch to Larkhall had been originally proposed but had been withdrawn, as in all probability this would be provided by the Caledonian Railway. They were now asking only for the main line from Blantyre to Wishaw, and this application was supported by all the local authorities, the traders, and the employers of labour in the district. It had been proved in Glasgow that by the facilities given by the tramways the population had been carried 171 times in the year—a total of 120,000,000 people—more than was carried yearly by all the railways in Scotland and Ireland. The reason for the railway companies' opposition was simply competition, but competition was really a reason for passing a rival railway and not a reason for rejecting it.

Local evidence having been given at considerable length,

The CHAIRMAN said they had had a great deal of evidence to show that the tramway would perform services which they could hardly expect the Caledonian Railway to perform.

Mr. JAMES STUART, C.E., said his estimate of the cost was £102,820, exclusive of the electrical equipment. The gauge would be 4ft. 8½in., which was the same as in Glasgow. They had agreed to pay to the Hamilton Corporation £11,500 for the purpose of street improvements.

Mr. R. W. HOGARTH (Messrs. Mathew Buchan & Hogarth) said there were no engineering difficulties. He considered the promoters' estimate was sufficient to admit of the constructional work being carried out in a thorough substantial manner in accordance with the best modern practice. The estimate for the electrical equipment was £85,000, which included the generating station, the overhead equipment, and the rolling stock. He had allowed for 20 motor cars, and a number of trail cars, which were attached at certain hours of the day only.

Mr. A. R. MONKS, managing director of the British Thomson-Houston Co., gave evidence as to the financial capacity of the company.

In support of the petition of the Caledonian Railway Co. Mr. PATRICK, general manager, said he did not know any district more fully developed by railways. The Caledonian Company was promoting a loop-line joining the Hamilton and Motherwell branch to their main line near Flemington, which would enable passengers from Blantyre to get to Hamilton, Motherwell, and Wishaw directly. They had had no application for extra trains, and no complaints as to the efficiency of their service. The proposed line was called a tramway, but it was a competing railway made on the public road—a condition which would give the promoters a tremendous advantage. The promoters were entirely foreign to the district, whilst the Caledonian had for many years contributed to the local taxation. They would, in his opinion, lose their money and do the Caledonian Company damage at the same time.

Local evidence was given to show that there was no popular demand for the scheme, and that there was not sufficient traffic to justify the construction of the tramway. After hearing counsel,

The CHAIRMAN intimated that the Committee were of opinion that the preamble was proved. The clauses having been adjusted the bill was ordered to be reported.

LINCOLN CORPORATION TRAMWAYS BILL.

The bill of the Lincoln Corporation to construct additional tramways came as an unopposed measure on Monday before Mr. J. W. Lowther, the chairman of Ways and Means, at the House of Commons. The preamble having been proved, the bill was ordered to proceed to third reading. The bill has already passed through all its stages in the House of Lords.

WESTON-SUPER-MARE TRAMWAYS BILL.

On Friday last the Select Committee of the House of Commons, presided over by Mr. de Tatton Egerton, gave their decision on the last bill confirming the provisional order granted by the Board of Trade to the Weston-super-Mare and District Electric Supply Co. (Ltd.) for the construction of electric tramways at Weston on the overhead trolley system. The Commercial Cable Co. strongly opposed the bill, contending that, as the delicate telegraph instruments at their cable station at Weston would be disturbed by electric leakage currents from the tramway, the tramway company should be obliged to bear any expense incurred in remedying such disturbance.

The CHAIRMAN said: The Committee has taken time to consider the question raised because it is one of grave importance. The question arose as to whether a precedent ought to be established either for or against the report of the Joint Committee of 1893 in connection with the working of tramways. The Committee have decided to pass the preamble of the bill subject to the insertion of a clause as follows:—

"This Act shall not be construed so as to prejudice or interfere with "any rights which the Commercial Cable Co. may by any court of "law having jurisdiction on the matter be held to possess under the "common law, either statute or otherwise, in regard to the uninter- "rupted user or enjoyment of their submarine telegraph cable now "running under the Bristol Channel to Weston, provided always that "the recommendations in the report of the Committee of 1893 in "respect to telephone companies' lines be carried out so far as they are "applicable to submarine telegraph cables."

In reply to Mr. Balfour Browne, Q.C., for the tramways company, the CHAIRMAN said: The Committee felt that they could not create a precedent either for or against the cable company, or alter or vary in any shape the 1893 report, and yet they felt that if they passed the preamble of this provisional order without any reference whatever the cable company in any action that might be taken would be seriously prejudiced by not having something recorded that contained the views of the Committee, therefore the Committee drafted the above clause. They wished to leave the cable company in the possession of every right which they now possessed, and it was not for the Committee to say whether they came within or without the provisions of the clause of 1893.

Mr. BALFOUR BROWNE: If they do come within you want the report to stand?—Yes.

Mr. BALFOUR BROWNE said the promoters accepted the clause suggested by the Committee.

The CHAIRMAN said the only alteration the Committee desired was to strike out the reference to the report of the Joint Committee.

Mr. BALFOUR BROWNE thought the alteration was important, as otherwise a court of law might say the whole report was thrown at it.

The CHAIRMAN said the Committee could not say whether the Commercial Company were or were not under the provisions of the recommendations of the Committee of 1893. They therefore desired, in the event of litigation, that the tramway company should not be able to plead statutory powers. The Committee proposed to embody in their report to the House the following:—

"In the course of the proceedings the attention of the Committee "was called to the position of cable companies in relation to other "electric undertakings, and it was sought to affirm that they were "under the provisions of the model clause based on the report of the "Joint Committee of the House of Lords and the House of Commons "on Electric Powers (Protective Clauses) issued in July, 1893. The "Committee declined to give a decision upon a point involving such "great national interests, and recommend that it should, with "other matters involving electrical interests, be again considered "by a similarly constituted Committee as has already adjudicated on "the subject."

The clause suggested by the Committee for the protection of the legal rights of the Commercial Cable Co. was, with the omission of the reference to the report of the Joint Committee on Electric Powers, added to the bill, which was ordered to be reported as amended.

WARRINGTON TRAMWAYS BILL.

The bill to confirm the order obtained by the Corporation of Warrington with reference to tramways came before the Select Committee of the House of Lords, of which the Duke of Northumberland is chairman, on Tuesday.

Mr. RAM said the object of the order was to enable the Corporation to construct tramways to be worked electrically. Of late much had been done in the borough in the way of street widening to render feasible a system of tramways. Several attempts had already been made to establish tramways, but without success, and the Corporation, therefore, were decided to move. Tramway No. 10 was the most important section, and at one place it crossed on the level of the line of the London & North Western Railway Co. That company objected to the crossing, alleging that it would be a constant source of danger, most prejudicial to the working of the traffic on the railway, and that the tramway was unnecessary, and not required in the public interest.

Major CARDEW (Messrs. Preece and Cardew) said the original scheme had been modified by the Board of Trade, particularly as regarded tramway No. 10. The board required, as a condition of power being taken, to construct a crossing on the level that their consent in writing should be first obtained. Speaking from past experience he said it would be perfectly practicable to carry out the promoters' intention in crossing the railway and working the proposed traffic. They did not expect to be able to run a quick service of trams, and they would undertake to pass the crossing at a walking pace.

Other evidence having been called for the bill,

Mr. MOON, on behalf of the London & North Western Company, said it could not be contended that the crossing of a railway on the level by an electric tramway could be unaccompanied by danger to the public. If the

Digitized by Google

bill were carried the traffic would increase, and so the danger would be intensified. If the Committee thought the tram should pass the railway at all he submitted it should be by a bridge, the whole cost of which should rest on the promoters.

Eventually the Committee passed the preamble, allowing tramway No. 10 as proposed, but adding a proviso that if the Board of Trade should order a bridge to be made the Corporation of Warrington should contribute half the cost.

SOUTHAMPTON TRAMWAYS BILL.

On Monday, the Select Committee of the House of Lords, of which the Duke of Northumberland is chairman, considered the bill to confirm the tramways provisional order granted to the Corporation of Southampton.

Mr. G. M. FREEMAN said this was an order authorising the Corporation of Southampton to construct additional tramways in the borough. By a local act of 1897 the Corporation were empowered to acquire tramways which had been previously in the hands of a private company, and to work them by mechanical power, and to spend £30,000 on the undertaking, including purchase; and having acquired the undertaking, they determined to equip it electrically on the overhead trolley system. They found it would be essential to extend the lines considerably. They obtained the consent of the Board of Trade to a large scheme, which had been approved by everyone except Messrs. Smith, a firm of drapers, who objected to a small portion of line. Messrs. Smith notified their objection to the Corporation, who decided not to work the line. Notwithstanding this, the petitioners had thought fit to commence an action in Chancery in regard to this piece of line and to pile up costs.

Eventually the Committee passed the preamble of the bill, an arrangement being come to with the petitioners.

GARSTON TRAMWAYS BILL.

On Tuesday the Duke of Northumberland's Committee of the House of Lords considered a bill confirming the provisional order granted to the Garston and District Tramways Co. (Ltd.).

Mr. WEDDERBURN, Q.C., for the company, said Garston was a residential suburb of Liverpool, and was a place of considerable commercial importance, having large docks and a large population. The original order for a tramway was promoted by a company, and it was opposed at first by the Garston District Council with a view to obtaining terms. Eventually an agreement was come to, under which the company, having obtained powers, were to construct a tramway; the company were then to sell the tramway to the Council, the price to be paid at the end of 21 years, the object being that the Council should not now have to raise money, which would not suit them; then, the company having sold, the Council were to lease the tramway to the company for 21 years, the company paying the Council £300 a year by way of rent. The result was that the Council need not borrow now. The £300 was intended partly as a contribution to the Council to enable them to meet the increased cost of keeping up the sides of roads which would result from the trams running along those roads. There was only one opponent, the Lancashire County Council, and they did not oppose the preamble but only sought to obtain certain clauses. The tram ran on a main road, and the District Council, having taken over powers from the County Council as road authority, received from the County Council a contribution in respect of the up-keep of that road. The County Council said that while the District Council was receiving this rent from the company, partly for the upkeep of the road, and the extra expense which would be caused by the trams, under the agreement they might spend the rent on anything they liked – there was no guarantee that they would spend it on the road. They therefore suggested that they should be given the £300, or such portion of it as would represent the increased cost of maintenance of the road due to the tramways. He urged, however, that the County Council had no *locus*.

Mr. FORBES LANKESTER, for the County Council, said the cost of the ordinary repairs and maintenance of a main road, whether the main road was vested in the County Council or in the local council, fell on the County Council, and it seemed therefore absolutely unarguable that if the County Council had to bear the extra cost, which it was admitted was incurred in the maintenance of these roads in consequence of the tramway, the District Council should not be able to object.

The Committee admitted the *locus* of the County Council.

Mr. FORBES LANKESTER said he would admit the preamble of the bill.

Mr. LESLIE said the trams would run for about 2 miles through a populous district, and that they had met with no opposition.

The Committee agreed to insert a clause to the effect that the amount which the County Council would, after the tramways were constructed, have to pay to the District Council should be reduced by £300 per annum for 21 years, that being the sum which the District Council under their agreement would receive from the company.

SOUTH-EASTERN METROPOLITAN TRAMWAYS BILL.

This bill, which authorises the conversion of the existing horse-tramway between Greenwich and Catford into electric lines to be worked on either the electric surface contact or electric trolley system, and which has already passed the House of Commons, was to have been considered yesterday by the Committee of the House of Lords, presided over by Lord Rosse, but it transpired that the opposition of the London County Council, asking for a veto on the system to be adopted, had been withdrawn, but on what terms was not stated. The bill, therefore, becomes an unopposed one, and will go before the Earl of Morley's Committee in the usual course.

THE SOUTH STAFFORDSHIRE TRAMWAYS BILL.

This bill, which has already passed through the House of Lords, was considered by the Unopposed Bill Committee of the House of Commons on Wednesday. The bill authorises the South Staffordshire Tramways Co. to sell and transfer portions of their undertakings to local authorities, to confirm a lease of their undertaking to the South Staffordshire Tramways (Lessee) Co., to re-arrange their capital, and for other purposes. The preamble having been formally proved, the bill was ordered to be reported for third reading.

SOUTH LANCASHIRE TRAMWAY BILL.

The protective clauses inserted in this bill at the instance of the local authorities, and which were excised in the House of Lords, have been re-inserted. Consequently the bill will now be treated as practically unopposed.

VALE OF RHEIDOL LIGHT RAILWAY BILL.

This bill, which seeks, *inter alia*, powers to alter the system of traction from steam to electric on the railway, came as an unopposed measure before Lord Morley's Committee at the House of Lords on Monday, and was ordered for third reading.

ELECTRICITY AND POTATO CULTIVATION.

In the House of Commons on Tuesday, Mr. AUSTIN asked if the attention of the Vice-President of the Board of Agriculture and Technical Instruction for Ireland had been directed to a series of experiments made by Mr. O'Sullivan, of Athea, Limerick, with a view of improving the present method of potato growing; whether he was aware that under this new system an increase of 80 per cent. in the crop was shown; and would the Department cause inquiries to be made into the matter.

Mr. PLUNKETT said his attention had been called to the experiments referred to, and he gathered that Mr. O'Sullivan attributed the extraordinary increase in his potato crop to the action of electricity introduced through lightning conductors and distributed through the crop by means of wires. As both the parish priest of Athea and the county surveyor of Limerick are satisfied both as to the effect and the cause of this remarkable phenomenon, he (Mr. Plunkett) had arranged to have inquiries made by the Land Commission on behalf of his Department.

LEGAL INTELLIGENCE.

Corporation of Hyde v. Oldham, Ashton & Hyde Electric Tramway (Ltd.), British Electric Traction (Pioneer) Co. (Ltd.), British Thomson-Houston Co. (Ltd.), and British Insulated Wire Co. (Ltd).

This case came before the Court of Appeal, composed of Lords Justices A. L. Smith, Vaughan Williams, and Romer, on Wednesday and Thursday on the appeal of the defendants from the judgment of Mr. Justice Grantham dated July 3, 1899. (The case was reported in *The Electrician* of July 7, 1899.) Plaintiffs in the action claimed an injunction restraining defendants from breaking open the footways in certain main thoroughfares of the borough of Hyde and laying thereunder electric cables for the purpose of working tramways which the defendants had constructed. The plaintiffs also claimed damages. Mr. Justice Grantham granted the injunction as claimed and awarded plaintiffs £100 damages, and from this decision the defendants now appealed.

Mr. Cripps, Q.C., and Mr. Bartley Dennis appeared in support of the appeal, and Mr. Macmorran, Q.C., and Mr. Sutton opposed it.

It appeared from the statement of Mr. Cripps that by the Tramways Orders Confirmation (No. 2) Act of 1896, Oldham, Ashton-under-Lyne and Hyde District, the British Electric Traction (Pioneer) Co. were authorised to construct the tramways in question, and the Oldham, Ashton & Hyde Electric Tramway (Ltd.) were their successors, the other defendants being the contractors employed to do the work. The plan for the construction of the tramways authorised by the Board of Trade under sec. 24 of the Act of 1896 involved the laying down of cables or feeders under the footways of the streets traversed. Disconnecting stations were authorised to be erected on the curb of the pavement at intervals of between a quarter and half a mile by means of which electric current might be disconnected from any section of the overhead wire. In July, 1898, plaintiffs received notice from defendants of their intention to open the ground of the streets along which the tramway was to pass for the purpose of laying the electric supply mains, &c. Defendants had undertaken to pay £500 towards the cost of widening certain streets, but plaintiffs declined to allow feeders to be laid under the footway unless defendants agreed to pay a further £500 towards widening the streets. Defendants, however, declined to pay any more, and claimed to be entitled to lay the feeders under the footways without the plaintiffs' consent by virtue of sec. 3 and sec. 25 of the Tramways Act, 1870, and their provisional order.

Lord Justice SMITH: The Mayor of Hyde said, "You can only put your wires under the roadway," and you say you can put them under the roadway plus the footway?

Mr. CRIPPS: Yes. The Corporation of Hyde said "We do not want to raise any question about that if you pay us another £500." I say we have a legal right to do it. I also say that if we did it wrongfully the plaintiffs are not entitled to an injunction, and that there ought to be no damages. Those are the two points I have to argue. The contention of

Digitized by Google

defendants in the Court below was that the term "road" mentioned in sec. 3 of the Act of 1870 was not limited to the carriageway, having regard to the defendants' second provisional order, which incorporated the Tramways Act of 1870. What the defendants did was to put certain pillars or posts, which were necessary to carry out the obligation of working the tramway imposed by the Board of Trade on the footway. That the defendants were entitled to do. But the defendants had to connect their wires with these posts, which was an essential part of their system, and therefore to a certain extent they had undoubtedly to carry their wires under the footways, as otherwise they could not have connected them with the posts. There is no contest on the point that in order to have an overhead system you have to have underground feeders.

Lord Justice ROMER: Yes; but there is no reason why these underground feeders should not be in the roadway.

Mr. MACMORRAN said that the posts were on the kerb, and to that the plaintiffs did not object; but they did object to the cables running under the footway, as it was constantly necessary for the defendants to take up the footway for the purpose of repairing them. The plaintiffs did not object to the feeders being under the roadway, but they said there was no reason why there should be underground wires under the footway at all.

Mr. CRIPPS: What is really the case here is that the Board of Trade have made these underground feeders an essential part of the defendants' system of tramway.

Lord Justice SMITH: Not necessarily under the footpath.

Mr. CRIPPS: But you must go under the footpath to a certain extent in order to get at the posts. Of course, my learned friend can say, "You must show power to do it," and my case is that having regard to the requirements of the Board of Trade and the posts with which the underground feeders must be connected, being on the footway, we cannot avoid the footway altogether in laying down these feeder wires for the overhead electric wire system in connection with tramway electric traction. The House of Lords had laid it down that the sub-soil was not vested in the local authority and was not a portion of the Corporation property. The defendants had as much right to put feeders there as the plaintiffs had the right to put gas pipes. The plaintiffs were not trespassers as the soil was not the plaintiffs. The plaintiffs were, therefore, not entitled to a mandatory injunction.

Mr. DENNIS, on the same side, submitted that if the injunction were granted it would be to the injury of the plaintiffs. Admitting the defendants were wrong and had to alter their system and put up overhead wires, that would be an eyesore to the public and an injury to the plaintiff. Were the plaintiffs and the public to be injured simply because the former might have a bare legal right?

Lord Justice SMITH: It is for the plaintiffs to judge of that.

Mr. DENNIS: It is for the Court to consider what the effect of granting an injunction would be. He submitted, in any case, that the circumstances here were not such as to warrant an injunction being granted.

Without calling upon counsel for the respondents, Lord Justice Smith, in giving judgment, after stating the facts, said the real point in the dispute was this: Could the tramway company justify breaking up the footway and putting in an electric feeder along the footway, under the Tramway Act of 1870 and the Order in Council? Mr. Justice Grantham had found they could not, and he (Lord Justice Smith) thought he was right in his finding. The Tramway Act of 1870 only applied to laying down tram lines in roadways. He could not see that it had any application to laying down electric feeders under the footpath. Then the defendants justified their conduct under the order in Council; one paragraph in particular of that order was relied upon by defendants as giving them power to lay under the footway electric feeders or cables along and underneath the footways of the borough.—Did it? The paragraph stated that under the provisions of this order the promoters might place and maintain on any street or road in which any of the tramways might be laid such posts and overhead wires as might be necessary for working such tramways. What was the meaning there? Was that authority to lay down a cable or electric feeder underneath the soil, or was it power to lay down something overhead and above the soil? He could not read it as meaning anything other than such posts and "overhead electric wires." He could not find any justification in the order in Council for what the defendants had done, or in the Tramway Act of 1870, against the will of the plaintiffs. He thought that Mr. Justice Grantham was right in granting a mandatory injunction because the evidence showed that, in spite of the objection of the plaintiffs, the defendants went on and persisted in laying down the cable under the footway. He thought that Mr. Justice Grantham's decision must be affirmed.

The other Lords Justices concurred, and the appeal was accordingly dismissed, with costs.

[Mr. Justice Romer during his remarks agreeing with the other Lords Justices read out a modification of the injunction which was accepted by the parties, it being stated by Mr. Cripps that the modification ordered by the Court of Appeal gave him hope that the parties would now be able to come to terms.—ED. *E.*]

Berry, Harrison & Co. v. Lockwood.

This case was heard in the High Court by Mr. Justice Bruce and a jury on Friday last.

Mr. FRANK DODD, Q.C., said the action was brought to recover £172, balance of an account for work done at the Garrick Theatre. The defendant was lessee of the theatre, and in December, 1899, he was about to produce "Puss in Boots." In one of the scenes a good deal of electric lighting was required, and plaintiffs carried out the work and put in the necessary fittings. In doing the work the requirements of the County Council, the Charing Cross and Strand Electricity Supply Corporation, and the insurance company had all to be complied with. The work was essential to the proper production of the scene and to the play. The defence was that the charges were excessive, but owing to defendants frequently requiring the stage for rehearsals and interfering with the work the charges were naturally increased. For materials and fittings the plaintiffs had not, in fact, charged the full list prices. Another defence was that defendant was only managing director of the Theatrical Production Syndicate (Ltd.), of which plaintiffs never heard until after the work was done. While the work was being done plaintiffs asked for a cheque on account and received one from defendant for £40. The full account of £212 was afterwards rendered and the balance was now sued for.

Mr. ERNEST L. BERRY corroborated counsel's statement.

In the result the jury found for plaintiffs for the amount claimed, and judgment was entered accordingly with costs.

A. Shanks & Son (Ltd.) v. Globe Electrical Co. (Ltd.).

This action was heard by Mr. Justice Grantham and a special jury on Monday and Tuesday (July 2 and 3). Mr. Scott Fox, Q.C., for the plaintiffs, said the action was brought to recover £120 on a bill of exchange of which the plaintiffs were drawers and holders, and which had been drawn upon and accepted by defendants, the Globe Electrical Co., London, with whom were joined the London & District Bank (Ltd.), as the plaintiffs alleged they were the same people. The real issue the jury would have to try was as to the constitution and reality of the Globe Electrical Co., because there was no dispute that plaintiffs had supplied a considerable quantity of machinery, value over £400, of which about £300 had been paid, leaving £120 due, for which this bill was given. He did not think it would be denied that the Globe Company had contracted to pay. The question was, who were they? Plaintiffs said they were the London & District Bank.

Mr. FOOTE, Q.C., for the defence, called evidence to prove that the London & District Bank had no connection with the Globe Electrical Co., but, on the contrary, had lost about £1,000 money lent to the man (Inrig) who traded under that style. The jury found for the defendant bank and judgment was given accordingly, with costs.

MUNICIPAL, FOREIGN & GENERAL NOTES.

Asylum Lighting.—A report by the Visiting committee of the Kidderminster Guardians in favour of the introduction of electric lighting at the asylum has been referred back.

Birstall.—The Council have been notified by the North British Electric Supply Co. of intention to apply for a provisional order.

Bolton.—Apparently the Corporation cannot appreciate a good servant until he is about to leave them. It is stated that the borough electrical and tramway engineer (Mr. Arthur Ellis), who was recently appointed electric tramway engineer at Cardiff and who proposes to take up his new appointment on Sept. 1, has now been offered an increase in salary of £150 per annum, in order to induce him to remain at Bolton; but Mr. Ellis points out that, having entered into an undertaking with the Cardiff Corporation, he cannot now honourably withdraw.

Blackpool.—An expenditure of £9,300 on new electric tramcars has been decided upon.

Bradford.—The Electricity committee recommend the Corporation to apply for sanction to a further loan of £140,000 for extensions to the Canal-road distributing station, for laying down additional mains, and for the erection of a new generating station.

Carnarvon.—The Council have referred a project for the erection of electricity works and for the construction of a light (electric) railway to a committee for consideration.

Cheltenham.—An inquiry was held on Friday into the application of the Corporation to borrow, among other sums, £20,100 for electric lighting extensions. The loan will be applied as follows: Extension of mains and new sub-stations, £914; street lighting, £2,530; house services (meters and fuse boxes), £365; cable boxes and labour, £165; transformers (ten 50kw.), £1,300; contingencies, £710; and alteration of voltage from 100 to 200 (already done), £2,100. Previous loans amounted to £101,952, of which £93,000 has actually been spent. The borough electrical engineer (Mr. Hamilton Kilgour), in support of the application, said the works were started in 1895, and in January last were supplying current to the equivalent of 22,650 8 c.p. lamps. At present there were 24,200 lamps connected, and in addition 212 arcs and 16 incandescents were used for street lighting. For the year ended March the trading profit was about £3,320. He said the change of voltage had involved the free supply of something like 5,600 new lamps, the supplanted ones being practically valueless. The change, however, had considerably increased the value of the undertaking. The result of the contemplated extensions would, he believed, be to raise the top load next Christmas to about 700kw., against a present top load of 300kw. Some of the new machinery was necessary in view of the expected demands for the proposed electric tramway to Cleeve Hill. The total length of the existing cables was between 60 miles and 70 miles, and there was a reasonable expectation of demands for the light coming in which would justify the extensions contemplated. Of the 10 new sub-stations three had already been erected; the sites for the others had not been definitely fixed. There was no opposition.

Digitized by Google

City of London.—The Streets committee has been authorised to remove all derelict and unidentified wires in the city, under the London Overhead Wires Act (1891) and the City Laws (1892).

Clewer (Windsor).—The Windsor Electrical Installation Co. have notified their intention to apply for a provisional order.

Croydon.—An extension of the arc lighting along the whole of the tramway route, from Norbury to South Norwood High-street, and to the Lower Addiscombe-road terminus, at an estimated cost of £3,360, has been sanctioned.

Derby.—The Corporation, on Wednesday, decided to lay electric lighting mains to the infectious diseases hospital at a cost of £850. The Tramways committee were instructed to prepare a scheme of electric tramways for the borough, and to take steps to obtain the necessary parliamentary powers.

Dover.—The Council propose to renew the electric lighting of the sea-front with festoons of incandescent lamps during the season. The terms of the Dover Electricity Supply Co., which is supplying current, are £45 for installation, maintenance, and removal, and £20 weekly for the supply of current for 14 hours per week. Additional hours to be at the same rate.

East Grinstead.—Mr. Robb, who recently submitted an electric lighting scheme for the town, has been asked to supply further details.

Edinburgh.—At a sitting of the Electric Lighting committee, on Tuesday, it was decided to recommend the Council to accept a tender, amounting to over £3,000, for coal-conveying plant for the McDonald-road electricity station. The question of providing a condensing tower was referred to a sub-committee.

Electric Driving for Printing Machines.—According to the printing trade journals a noticeable feature of the printing exposition and fair held recently at the Grand Central Palace, New York City, was the application of the electric motor to all classes of printing machines and apparatus.

In the United States Government new printing offices at Washington there will be installed 7,000 incandescent lamps, the whole of the building is to be ventilated by electrically-driven fans, 12 electric elevators have been provided, and all the printing presses are to be run by electricity, the larger-sized machines being provided with independent motors. Current will be generated from plant installed in the works.

Electric Power Schemes in Australia.—A company entitled the Victoria Light, Heat & Power Corporation has been formed for the purpose of supplying electric current for lighting, traction and power in the suburbs of Melbourne within a 10-mile radius. It is estimated that a capital of £7,000,000 will be required for the undertaking. It is proposed to supply current for driving in factories in the metropolitan area. The tramway scheme includes a tunnel under the Yarra, to cost between £60,000 and £100,000, and the tramways are to be taken across the Williamstown railway line. The Williamstown Council has referred the matter to a committee.

Electrical Enterprise in Italy.—Statistics issued in the *Gazetta Ufficiale* (Rome) of June 8 give the total length of electric tramways in Italy on Jan. 1 last as 1,974 miles, distributed as follows :—

Lombardy	653 miles.	Sicily	63 miles.
Piedmont	561 „	Apulia	39 „
Emilia	278 „	Campania	38 „
Venice (Province)	150 „	Other Provinces	69 „
Tuscany	123 „		

Fleetwood.—Electric current is now available, and the esplanade was illuminated for the first time last evening by arc lamps.

Glasgow.—In our last issue we gave a brief extract of the accounts of the Glasgow tramways department for the year to May 31. The revenue from the electric cars has been maintained at nearly 14d. per car mile, the total receipts from the section for the year amounting to £53,711. 18s. 8d. The following figures show the operating expenses per car mile by horses and by electricity :—

Power	3·78d. horse.		0·92d., electric.
Traffic	3·05d. „		3·00d. „
General	0·67d. „		0·70d. „
Maintenance	1·32d. „		1·64d. „
	8·82d. „		6·26d. „

Under the heading power for horse traction are included cost of feeding, wages of stablemen, veterinary expenses, shoeing expenses, for electric traction, wages in power station, coal, and other sundry expenses at the power station. In addition to this saving in expenditure there is a large increase in revenue from the electric cars. The balances from the horse and electric traction accounts (£125,243. 19s. 8d.) have been carried to net revenue account. The tramways department borrowed during the year £345,000.

Grantown (N.B.).—The Police Commissioners are divided on the electric lighting question, some members favour the erection of municipal works and others prefer that a company should come in. Reports from Messrs. Lyon & Crosbie and Mr. Druitt Halpin were discussed at a special meeting of the Commissioners last week. Messrs. Crompton & Co. also offered to established electricity supply works at their own cost and risk. They would bear the expense of obtaining a provisional order and would supply current for lighting at 8d. per unit for the first hour and 5d. after. On a division the Commissioners were equally divided, and the chairman declining to give his casting vote, the matter remains in abeyance.

Halifax.—The Corporation on Wednesday considered a recommendation to increase the salary of the electrical engineer from Oct. 1 next. Dr. W. Smith moved an amendment that the matter be referred back. Ald. Spencer strongly urged the Council to approve the proposed increase ; Mr. Street was well worth the money, and their electrical department required and must have a capable chief. Mr. J. W. Hartley pointed out that their engineer had turned a loss of £800 into a profit of £5,000. Comparing the salaries paid by other towns of similar output, his salary was a low one. They drove a good man away in Mr. Wilmshurst, and now they were trying by their policy of so-called economy to drive another away. The amendment was carried by 22 votes to 19. Another amendment, however, moved by Ald. Spencer, to delete all reference to an advance to £500 in twelve months, and to confirm the proposed advance to £400, was eventually carried by the mayor's casting vote.

Heswall (Cheshire).—The Heswall Gas & Lighting Co. intend to apply for a provisional electric lighting order for Heswall, Barnston, Pensby and Gayton.

Hornsea.—A special meeting of the Council will be held on 16th inst. to consider particulars regarding the proposal to construct a light (electric) railway between Hornsea and Driffield, and also to establish electricity supply works for lighting and power in the town. Messrs. Bennett and Ward-Thomas are consulting engineers for the scheme.

Hornsey.—On Monday the Electricity committee reported that they had further considered the electric lighting question, and advised the Council to decline the offers received for a transfer of their provisional order. They recommended the Council, subject to modification of details, to carry out the scheme recently prepared by Mr. Robert Hammond, involving an expenditure of £73,350, to apply for the necessary borrowing powers, and to appoint Mr. Hammond consulting engineer. The report was, after discussion, adopted.

Hull.—A sub-committee has been appointed to report upon the advisability of reducing the price of electric current for power.

Ilfracombe.—The question of transferring the Council's electric lighting order to a company is under consideration by the General Purposes committee.

Kirkcaldy.—The Council have considered the report of their consulting engineer (Prof. A. B. W. Kennedy) on the electric lighting and traction project. In connection with the tramway scheme, the report was remitted back to enable the committee to report upon the relative cost of alternative routes.

Leamington.—Acting on the advice of the General Purposes committee, the Council have offered to purchase the undertaking of the Midland Electric Light & Power Co. for £17,000. The committee obtained a report on the value of the undertaking from Mr. Horace Boot, of Tunbridge Wells.

Light Railways.—The Bromsgrove Light Railway order has been submitted to the Board of Trade for confirmation. Objections by July 21.

The chairman of the Tramways committee (Mr. Boyle) explained at the Corporation meeting on Wednesday the provisions of the agreement made between the committee and the Manchester Tramways & Carriage Co. He said the main purport of the scheme was that they recognised at once, in view of the fact that they had had to face the reconstruction of the whole of the lines—a thing which they had not anticipated at the time the committee was formed—and in view of the difficulty of getting materials, overhead equipment and cars, that they would not be able by the date when the lease expired to take over the system and work it by electricity. The present proposal was that they should make an agreement with the company whereby, before the expiration of the lease the committee should be at liberty to enter upon the work of reconstruction, and thus be able to take over the lines as they became ready. That would mean that they would have electric traction on some routes at an earlier period than would otherwise be the case. The committee had guaranteed to the company up to May 31, 1902, the profits that had been made previously. If, after May 31, 1902, the committee were not ready to take over any lines, and if there should be any sections still unequipped from that date the committee guaranteed that the company should be paid by mileage in respect of those lines they still worked. After discussion the agreement was approved.

Messrs. Bennett & Ward-Thomas have notified the Carnarvon Council, on behalf of a syndicate, that they propose to apply, under the Light Railways Act, for permission to construct a light (electric) railway from Carnarvon to Bethel, Ebenezer and Bethesda, with a

Digitized by Google

branch to Dinorwic. It is also proposed to construct a light railway from Carnarvon to Dines Dinlle.

The Duke of Cambridge has intimated his intention to oppose the application of the British Electric Traction Co. for power to construct an electric tramway from Kingston Vale to Esher. The Surrey County Council and the Kingston Corporation, who have rival schemes, will also oppose.

London County Council.—At Tuesday's weekly meeting it was agreed that the Council should exercise its right to require the London, Deptford & Greenwich Tramways Co. and the South London Tramways Co. to sell their undertakings to the Council.

Electricity loans of £20,000 to Poplar, of £5,147 to Battersea, and of £6,935 to Islington were approved. Application has been made by the Strand District Board for a loan of £1,500 repayable on the annuity system within 10 years for the purchase of two motor vans for dirt collecting and street watering. The Finance committee recommended that the application be granted. Mr. SPOKES asked if there was any precedent for such a loan?—Mr. BRUCE said there was no precedent. The committee had reports from its officers that such a loan could properly be made. The recommendation was carried.

Manchester.—The accounts of the Electricity Department for the year ended March 31, now issued, show the total number of units accounted for amounted to 6,468,405, an increase of 24 per cent. over the previous year. The consumers numbered 3,240, an increase of 670. 47 miles 530 yards additional mains were laid, making the total 110 miles 45 yards. Revenue derived from sales of current, &c. (which works out at 3·20d. per unit), amounted to £86,297. 18s. 4d., and working expenditure to £49,905. 11s. 6d., showing a gross profit of £36,392. 6s. 10d. From this is deducted £27,199. 15s. 5d. on account of interest and sinking fund, leaving a net profit of £9,192. 11s. 5d. This surplus, together with £2,000 from last year and £572. 6s. 5d. interest on reserve fund investments, making a total of £11,764. 17s. 10d. has been appropriated as follows:—In aid of rates, £10,000; reserve, £1,764. 17s. 10d. The total capital expenditure was £641,821. 18s.; mortgage debt, £556,278. 9s.; mortgages redeemed to date by action of sinking fund, £49,232. 11s.; balance at credit of renewals suspense account, £335. 4s. 5d.; ditto reserve fund, £13,360. 15s. 2d. Owing to the necessity for renewing a considerable length of mains which had proved defective, the charge upon revenue for repairs and renewals of mains was £7,453. 10s. 6d., against £1,495. 12s. 6d. last year. In addition, £12,459. 10s. 6d. had been taken from the renewals suspense account to cover similar expenditure. The accident at the Dickinson-street station, in September last, did considerable damage, and the sum withdrawn from reserve on account of the breakdown was £7,069. 18s. 1d. The Committee are pushing forward the equipment of the Bloom-street station in order to meet the increasing demand for electrical energy, and to be ready to supply current for working the tramcars. Plans have been approved for the equipment of a part of the Stuart-street station. Considerable progress has been made during the year with the laying of electric mains in Withington, Moss Side, and Levenshulme. Current has been available in portions of Moss Side since December, and in Withington since February last. On Sept. 30 the price of electric current to long-hour consumers was reduced from 1½d. to 1¼d. per unit, and a similar reduction was made in the price for motor power.

Malton (Yorks.).—The agreement with the Northern Electric Supply Association in connection with the proposal to establish electricity works has been signed.

Market Harborough.—A communication has been received from a company asking for sanction to a proposed application for a provisional order.

Marriage.—On Wednesday, at Knaresborough, Mr. C. A. Midgley, city electrical engineer to the York Corporation, was married to Miss Marguerite Emily Simpson, only daughter of Mr. G. E. Simpson, of York and Knaresborough.

Matlock.—Notice of intention to apply for a provisional order has been given by the North British Electric Supply Co.

Melrose.—Messrs. Crompton & Co.'s proposals for the erection of electricity supply works in the district have been approved, and their application for a provisional order will not be opposed.

Municipal Telephony.—A special meeting of the Norwich Town Council was held on Tuesday, when it was decided to approve the application of the Norwich Mutual Telephone Co. for a telephone licence for the Norwich area. The agreement with the company provides for the supply of a constant and continuous telephone service at low rates; that no preference be given to any subscriber; that a reduction be made for the cost of telephonic service to subscribers when the company's receipts exceed a specfied aggregate amount; that the Corporation, under sanction of the Postmaster-General, may purchase the plant compulsorily on Dec. 31, 1911, or Dec. 31, 1916 (in 1911 at fair market value as a going concern, with an additional sum equal to three years' profits in addition; in 1916 on the same terms, but with two years' profit in addition); that, subject to any prior rights of the Postmaster-General, the Corporation be able to purchase at the revocation or determination of the licence; that the company does not assign, underlet, or otherwise dispose of the licence; that the Corporation be represented on the board of the company by two directors; that wayleaves, poles, tubes, &c., be allowed subject to direction of the city engineer; that the Corporation may determine the agreement if a telephone exchange for 200 subscribers and with 3 miles of cable is not laid down in three years, or in the event of failure to perform other conditions of the agreement, or if the company is ordered to be wound-up. The subject was discussed at considerable length by the Council on Tuesday, when it was resolved that the whole of the plant and appliances of the Company should be new and of the most modern and approved description, and that it shall not be competent for the company to acquire or utilise the business or any part of the plant or appliances of any other firm or company.

Owing to the limited success of the circular canvass the Grantham Council has now decided to make a personal canvass of ratepayers to ascertain the number of probable subscribers to the suggested municipal telephone exchange.

Obituaries.—We have to record the death of Mr. Henry Reason, managing director of the Reason Manufacturing Co, which recently took place at Rockhampton, Queensland. In company with Mr. Arthur Wright, Mr. Reason left England some two months ago for Australia, in order to report upon the proposal to establish electricity generating works at Brisbane. The two gentlemen intended to return home by way of America, in order that they might perfect their knowledge of the different electric light installations in force in the principal towns of the United States. Mr. Reason was the founder of the Reason Manufacturing Co. of Brighton (from small beginnings) in 1887. Mr. Reason was only 37 years of age, and leaves a widow but no children.

The death is announced of Sir Robert Murdoch Smith, director of the Museum of Science and Art in Edinburgh. Sir Robert was born at Kilmarnock in 1835, and was formerly a major-general in the Royal Engineers. His principal work was connected with the development of Indo-European telegraphs, especially the Persian Gulf section, and after many years' experience as director-in-chief of the Indo-European Telegraph Department, he was sent to Persia in 1887 on a special Foreign Office mission, and for this was created a K.C.M.G.

We have also to record the death of Mr. Montagu Charles Dent, A.M.I.E.E. (Messrs. Wallis-Jones & Dent), which took place on June 28, after a short illness subsequent to an internal operation. Mr. Dent was educated at Eton and King's College, and from 1892 to 1894 served his time with Messrs. Robey & Co. and at the Loughborough works of the Brush Company from 1894 to 1896. During 1896 and part of 1897 he was employed on installation work at Arundel Castle, on central station work at the Wandsworth electricity station, and in the erection of the exhibition plant at Earl's Court. In October, 1898, he joined Mr. Reginald J. Wallis-Jones in partnership as consulting engineers, and carried out several important installations of electric light and power plants.

The death is announced of Mr. Arthur Albright, senior partner of Albright & Wilson, chemical manufacturers, of Oldbury. Mr. Albright, had reached his 90th year.

The death is also announced of Mr. James Doulton, of Lambeth Pottery, London, S.E.

Padstow.—The Lighting committee has been instructed to report upon the advisability of adopting electric lighting.

Pickering.—The Council will on Monday meet representatives of an electricity supply company which proposes to apply for a provisional electric lighting order for the district.

Provisional Order Transfers.—The Board of Trade have approved the transfer of the Bridgend Provisional Electric Lighting order to the English Industrials (Ltd.).

The transfer of the Lewes Electric Lighting Order (1898) to the County of Sussex Electric Power Distribution Co. was formally sealed on Wednesday.

Ripon.—The Council considered, on Thursday last, a proposal to erect electricity works. Some members of the Council favour the introduction of electric light, and "for the present, at all events, the introduction of a scheme by a company will be opposed."

Salford.—The Corporation had before them on Wednesday a report from the Tramways committee on the negotiations with the Manchester Carriage & Tramways Co. in regard to the future working of the tramways in the borough. The Corporation were recommended to discontinue negotiations with the company for the working of the tramways in Salford and Eccles and the Swinton and Pendlebury districts after April 27, 1901, and that steps should be taken at once to enable the Corporation to work the tramways after that date by horse traction until such time as arrangements were completed for electrical working. After discussion this was agreed to, and the Tramways committee were instructed to prepare plans and estimates.

Digitized by Google

Southport.—An inquiry was held here last week into the application of the Council to borrow £9,200 for electric lighting extensions and £13,000 for a refuse destructor. It was also stated that the Corporation had power to borrow £138,500 for electricity supply, and up to March had spent £100,136. They were putting down continuous-current plant for the supply of current for the new electric tramways. They were also prospective customers in the Southport Pier Co., which runs a tramway on the pier, the promoters of the Ormskirk light railway, and the Southport and Lytham tramways, and also in the Lancashire & Yorkshire Railway Co., who contemplate the erection of a new station at St. Luke's.

A Board of Trade inquiry will be held on 17th inst. into the application of the Corporation to borrow £40,000 for re-constructing the tramways recently purchased from the Birkdale & Southport Tramways Co.

The first official trial trip over the new electric tramway route—from London-street to Blowick—took place on Friday last. The Board of Trade inspection of the line takes place on the 17th inst., and the formal opening has been fixed for the following day.

Stretford.—The Council have approved the agreement with Manchester for leasing the local tramways for 21 years. The lines are to be converted to electric traction and worked in conjunction with the Manchester Corporation tramway system.

Sunderland.—The fifth annual report of the Electricity Department has been issued. On March 31 the equivalent of 35,024 8 c.p. lamps were connected, an increase of 36 per cent. in the year. The number of units sold had advanced from 472,343 to 640,079, 35 per cent. The gross profit on the 12 months was £4,047. 6s. 4d., and after paying sinking fund and interest there was a net profit of £466. 15s. 7d. The gross profit for the previous year was £2,865. 17s. 9d., and the net profit £364. 11s. 3d.

The 1850 Anglo-French Cable.—It is announced that the jubilee of the laying of the brothers Brett's submarine telegraph cable between Shakespeare Cliff, Dover, and Cape Grisnez, France, is to be celebrated at Calais on August 28th, the day in 1850 when the "Goliah," starting from Dover, paid out the cable. There was, as is well known, no actual communication by this cable until later in the year.

Tramway Extension in Middlesex.—At the last meeting of the Middlesex County Council the Parliamentary committee recommended that the London United Tramways (Ltd) should be informed that the Council would limit its opposition to clauses in the company's bill if the latter and the councils affected would consent to the County Council being the purchasing authority under the bill. A long discussion ensued, in the course of which it was stated that the eight district councils affected supported the bill, and that the company was expending £120,000 on improving the main roads. The recommendation was carried.

Tramways in Ireland.—The Council of the Dublin Chamber of Commerce has unanimously approved the principle and objects of the Tramways (Ireland) Act Amendment Bill now before Parliament, which is intended to extend to Ireland the facilities of the Light Railways Act of 1896.

Trowbridge.—Mr. D. Stevenson has been appointed consulting engineer to advise upon the suggested electric lighting and refuse-destructor project.

Wakefield.—A formal inquiry was held here on Wednesday into the application of the Corporation to borrow £25,000 for electric lighting extensions. Of the new loan, £7,853. 16s. 7d. is to meet excess of expenditure over borrowing powers.

West Bromwich.—The Local Government Board have sanctioned the borrowing of £30,000 for the erection of electricity works.

Workhouse Lighting.—The Christchurch Guardians have decided to substitute electric for gas lighting at their workhouse. A report by Mr. G. R. Peers, of Manchester, puts the total cost of the installation at £1,610, with an annual charge for maintenance of about £150.

Worthing.—Forty 1,000 8 c.p. arcs are to be employed for street lighting instead of 76 50 c.p. incandescents as originally proposed. The change involves an additional capital cost of £768 and an increase in the annual cost of maintenance, &c., of £122.

Condenser Contracts.—The Wheeler Condenser & Engineering Co. have secured the contract for condensing plant (in duplicate) required for the Lisbon power station of the Portuguese Tramway Co. The Wheeler Company are also supplying the cooling tower and condensing plant required for the Bromley (Kent) Electric Light & Power Co.'s station. Among other recent orders received are the duplicate plants for the municipal stations at Belfast and St. Helens, of the Reading Electric Supply Co., and of the Bedford, Blackpool, Devonport, and West Bromwich Corporation electricity stations.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

TENDERS INVITED.

Beckenham District Council invite tenders for the "free" wiring of premises. Specification may be obtained from the consulting engineer (Mr. R. P. Wilson), 66, Victoria-street, Westminster, S.W., or from the borough engineer and surveyor (Mr. A. Angell) Tenders to the clerk (Mr. F. Stevens) by 4 p.m. of July 16. See advertisement.

The Electric Lighting committee of the Vestry of *St. Mary, Islington* (London) require tenders for relaying York and other stone, and providing new York and other stone where necessary, over the electric conduits and mains which may be required during the ensuing three years. Further particulars are set out in an advertisement, and specifications may be obtained after 9th inst. at the electricity department, 50, Eden-grove, Holloway, N. Tenders to the vestry clerk (Mr. Wm. F. Dewey), Vestry Hall, Upper-street, N., by noon of 25th inst.

Wimbledon District Council require tenders for supplying and fixing telephones at their isolation hospital. Tenders addressed to the clerk (Mr. R. H. S. Butterworth), Council Offices, Broadway, Wimbledon, by 18th inst. See advertisement.

Lowestoft Corporation require tenders for (1) direct-current meters, and (2) cutouts. Specifications, &c., can be had from Mr. R. Beattie Nicholson, town clerk, and can be seen at, but not obtained from, the office of Mr. W. C. C. Hawtayne, 9, Queen-street-place, London, E.C. Tenders to Mr. Nicholson, town clerk's office, Lowestoft, by noon of July 10. An advertisement contains further particulars.

Huddersfield Corporation Electricity committee invite tenders for single-phase steam-generating plant of 1,000kw. capacity. Specifications, &c., can be obtained from Mr. A. B. Mountain, borough electrical engineer, Electricity Works, St. Andrew's-road, Huddersfield, and tenders must be sent to Mr. F. C. Lloyd, town clerk, Town Hall, Huddersfield, by Thursday, July 12.

Rugby District Council invite tenders for taking a lease of their provisional electric lighting order (1898). Applications to Mr. T. M. Wratislaw, clerk and solicitor, Council offices, Rugby, by Aug. 1. See advertisement.

Extension of Time.—The date for tenders for the overhead equipment for about 16 miles of equivalent single track of tramways, for the Corporation of *Durban*, Natal, has been extended. Tenders (in duplicate) to Messrs. Webster, Steel and Co., 5, East India-avenue, London, E.C., by July 20, or to town clerk, Durban, on or about Monday, Aug. 13.

Extension of Time.—Tunbridge Wells Corporation invite tenders for telephone instruments, apparatus, material, and accessories. Tenders to town clerk, Town Hall, Tunbridge Wells, by July 12.

Partick Commissioners invite tenders for the supply and laying of insulated electric mains, conduits, junction boxes, cast-iron arc and incandescent lamp standards, arc lamps, automatic switches, &c. Tenders to town clerk, 97, West Regent-street, Glasgow, by July 10.

Hammersmith (London) Electricity and Lighting committee invite tenders for insulated high and low-tension cables, junction boxes, &c., and cast-iron pipes, draw-box covers, &c, required, as per schedule, for 12 months. Tenders to chairman by July 12.

Grays Thurrock District Council require tenders for electricity generating plant. Tenders to clerk by noon of Aug. 9.

Croydon Corporation invite tenders for the reconstruction of the present tramway track and the construction of new tramways and paving of roads. Tenders to town clerk by noon of July 10.

Salford Corporation require tenders for overhead equipment for tramways, exclusive of steel poles. Tenders to town clerk by July 16.

Limerick Corporation require tenders for the supply and erection of electrical plant and apparatus. Tenders to town clerk by July 14.

Blackpool Corporation invite tenders for trolley poles, cables, and trolley wire, boosters, switchboards and storage battery. Tenders to chairman Electric Lighting and Tramways committee by July 23.

London County Council require tenders for the supply (within three months of order) of about 70 arc lamp standards for lighting Victoria Embankment. Tenders to clerk (Mr. C. J. Stewart) by July 10.

Hackney (London) Electric Light committee require tenders for 220 arc lamp pillars. Tenders to clerk by July 11.

Trimdon (Co. Durham) Parish Council invite tenders for public lighting by electricity or acetylene gas. Tenders by July 17.

Southend Council invite tenders for electric traction plant, about 1,180 tons of steel rails, 46 tons of steel fish-plates, &c. Tenders to town clerk by July 25.

Digitized by Google

Cardiff Corporation require tenders for about 1,000 tons of tramway rails, fish-plates, sole plates, tie bars, bolts and nuts, points and crossings, copper rail bonds, &c. Tenders to townclerk by July 12.

Wolverhampton Tramways committee require sketch plans and models of single and double-decked electric tramcars. Application to borough engineer.

Birkenhead Corporation require tenders for erecting new tramcar sheds. Tenders to town clerk by 24th inst.

Newport (Mon.) Corporation require tenders for construction of about 1½ miles of double tram track. Tenders to town clerk by 9th inst.

Salford Tramways committee require tenders for steel points and crossings. Tenders to chairman by 17th inst.

Bermondsey (London) Vestry require tenders for the erection of electricity generating and dust destructor buildings. Tenders to vestry clerk by 26th inst.

Halifax Tramways committee require tenders for brass journals and trolley fittings for six months. Tenders to town clerk by 11th inst.

Central Electric Supply Co. (Ltd.), 19, Carnaby-street, Golden-square, London, W.C., require tenders for clearing site of proposed generating station at Grove-road. Tenders by 9th inst.

Baden State Railway authorities invite tenders until July 25 for the supply of two polyphase machines for the electric lighting station at Mannheim. Tenders to the general direction of the Grossh. Badische Staats Eisenbahnen, Carlsruhe, Germany.

Roumania Post and Telegraph Authorities (Bucharest) invite tenders until 17th inst. for the supply of 40 tons of galvanised steel wire, 2mm. diameter.

TENDERS RECEIVED AND ACCEPTED.

The directors of Madame Tussaud & Sons (Ltd.) have received the following tenders for the extension of their electric lighting plant. Mr. R. W. Weekes is consulting engineer for the work. The specification included two 30kw. steam dynamos, two Babcock-Wilcox boilers, switchboard, and connecting cables :—

	Dynamo.	Engine.	
*Johnson & Phillips	Own	Alley & MacLellan...	£1,775
D. Bruce, Peebles & Co.	do.	Willans	2,158
Ditto	do.	Browett-Lindley	1,948
Ditto	do.	Reavell	1,928
Ditto	do.	Alley & MacLellan...	1,918
Christy Bros. & Middleton	Crompton	Willans	2,154
Ditto	do.	Browett-Lindley	2,126
Ditto	do.	Allen & Co.	2,116
Ditto	do.	Reavell	1,924
J. H. Holmes & Co.	Own	Willans	2,150
Drake & Gorham	Parker	do.	2,058
Crompton & Co.	Own	do.	1,963
Ditto	do.	Reavell	1,722

The tender of Messrs. James Simpson & Co., of Pimlico, was accepted for the supply of pipes, feed pumps, heater, &c., at £550.

* Accepted under guarantee to deliver and erect one steam dynamo in eight weeks.

The following tenders have been accepted by the Dartford Council for the supply of electricity generating plant :—

James Carter & Sons (Lancashire) boilers with fittings, economiser, feed pumps, &c.)	£1,545	19	0
James Carter & Sons (automatic stokers)	249	0	0
Aiton & Co. (pipework)	660	0	0
G. S. De Ritter (surface condensing plant)	620	0	0
Reavell & Co. (two dynamos, with vertical enclosed high-speed engines and motor boosters)	2,247	0	0
Marquand Accumulator Co. (storage batteries)	725	0	0
Ditto (maintenance for five years)	275	0	0
Veritys Limited (main switchboard and connections)	667	0	0
Carrick & Sons (6-ton overhead traveller)	162	0	0
Western Electric Co. (underground mains, conduits and roadwork for private and public lighting)	4,866	0	0
Ditto (enclosed arc lamps and posts)	184	0	0
L. G. Tate (station lighting)	39	10	0

Bermondsey (London) Vestry have received the following tenders for the supply of insulated electric mains, conduits, junction boxes, &c.

W. T. Glover & Co. (*accepted*)	£8,134	7	9
St. Helen's Cable Co.	8,109	16	8
Siemens Bros. & Co.	8,113	9	11
Callender's Co.	8,212	7	1
Western Electric Co.	8,219	11	11
British Insulated Wire Co.	8,643	15	10

The St. Pancras (London) Vestry have received the following tenders for the supply and laying of cables in the Hampstead, Tottenham Court and Euston-roads :—

Western Electric Co. (*accepted*)	£2,618	9	8
British Insulated Wire Co.	2,675	10	2
Siemens Bros. & Co.	2,575	15	4
Callender's Co.	2,506	12	2

Subject to the sanction of the Local Government Board, the West Ham Guardians have accepted the tender of Messrs. Frank Suter & Co. for supplying and erecting electricity generating plant, and for wiring and fitting the workhouse and school premises at £5,252.

Cheltenham Town Council have accepted the tender of Messrs. Carrick & Ritchie for a hand-operating crane at the electricity works at £260.

Manchester Tramways committee recommend the acceptance of the tender of Messrs. Macartney, McElroy & Co. for the electrical equipment of three tram routes, at £16,251. 6s. 6d. The three routes are Cheetham Hill, Rochdale-road and Bury New-road, and represent about 10 miles of track.

APPOINTMENTS VACANT AND FILLED.

British North Borneo Co. require a superintendent of telegraphs. An advertisement contains further information, and applications must be made to the secretary, 15, Leadenhall-street, London, E.C., from whom further particulars can be obtained.

Salford Electric Light committee invite applications for the position of engineer to their electrical undertaking. Further particulars are set out in an advertisement, and applications are to be sent to the town clerk (Mr. L. C. Evans), Town Hall, Salford, by 14th inst.

The governors of the Technical Institute, Wandsworth, London, S.W., require a qualified teacher to take classes in electric testing and wiring. Some particulars are given in an advertisement, and applications must be in by July 19.

A junior demonstrator in physics is required for the South Western Polytechnic, Manresa-road, Chelsea, S.W. An advertisement contains further particulars, and forms of application may be obtained from the secretary.

Wimbledon District Council require a temporary draughtsman for the electricity works extension. Applications to the clerk (Mr. R. H. S. Butterworth) by July 10. See advertisement.

Lecturers and demonstrators in mechanical engineering, and in physics and electrical engineering are required for the Derby municipal technical college. Applications to principal by July 9.

A lecturer in engineering is required for the Portsmouth Municipal Technical Institute. Applications to principal by 19th inst.

Swansea Corporation require a resident electrical engineer. Applications to town clerk by July 9.

Mr. U. Barbieri, first-class electrician in the Argentine Navy, has been appointed chief electrician to the Navy, in place of Mr. J. A. Newbery, recently appointed to the position of director of public lighting to the city of Buenos Ayres.

Mr. Samuel Jones, at present in the service of the Shoreditch Electricity Department, has been appointed generating station assistant to the Reading Electric Supply Co.

Colchester Corporation have appointed Mr. A. R. Sillar, the present station manager to be permanent borough electrical engineer.

BANKRUPTCIES, LIQUIDATIONS, &c.

Notice is given that creditors of Dobson & Curtis Bros. (Ltd.) in liquidation, who have not sent in their claims as requested in a previous notice must do so before Monday, 9th inst. Otherwise their claims will be excluded.

Resolutions to wind up voluntarily the Premier Electric Lamp Syndicate (Ltd.) for reconstruction and to appoint Mr. D. L. Chalmers as liquidator have been passed and confirmed. The new company will be entitled the Premier Electric Lamp Co. (Ltd.).

Mr. G. F. Clarke, 71, Cross-lane, Earlstown, Lancs., has been appointed trustee in the bankruptcy of G. H. Bentley, electrical engineer (formerly trading at 18, Market-street, Earlstown).

At the London Bankruptcy Court on 29th ult. Mr. Registrar Brougham gave judgment on the application of John Evelyn Liardet for the Court's approval to the scheme of arrangement recently entertained by the creditors. His Honour said the scheme provided for the payment to the creditors of a composition of 20s. in the £ by cumulative preference shares in Motors and Mechanical Appliances (Ltd.) which was to be formed to acquire and work debtor's inventions, or to those creditors who preferred money, a cash composition of 7s. 6d. in the £. The creditors with one exception had decided to take the composition in shares, but the Act provided that the Court could not sanction a scheme unless it provided reasonable security for the payment of not less than 7s. 6d. in the £. He could not hold that shares in a company which was not even formed provided that reasonable security, and as the amount required to pay 7s. 6d. on all the unsecured debts had not been deposited with the Official Receiver, he had no option but to refuse to confirm the scheme. The scheme was accordingly rejected.

Henry Vincent James, electrical engineer, trading as H. V. James & Mills, Croft-street, and residing at 44, Bolton-road, Pendleton, Salford, has executed a deed of arrangement, with liabilities £2,444. 12s. 8d. and assets £1,352. 7s. 10d. Mr. I. Senior (30, East-parade, Leeds) and another have been appointed trustees.

Digitized by Google

Sale by Tender.—Leeds Corporation are open to receive tenders for two horizontal Fowler engines of 400 I.H.P., two sets of Greenwood and Batley dynamos, one spare armature to fit any dynamo, and a switchboard and instruments, the plant being at present in use in connection with the Corporation's system of electric tramways. Particulars will be found set out in an advertisement elsewhere, and it is notified that the plant will be available for removal about February next. Further information can be obtained from Messrs. Hopkinsons and Talbot, 26, Victoria-street, London, S.W.

Sale by Auction.—Messrs. John M. Leeder & Son will sell by public auction at the Port Tennant Copper Works, Swansea, a large quantity of contractor's electric and other plant, machinery, &c., particulars of which are set out in an advertisement. The sale takes place on Thursday next at 11 a.m. Catalogues are in course of preparation, and may be had of the auctioneers, 46, Waterloo-street, Swansea.

"Paragon" Fan Motors.—The Edison & Swan Co. have just issued leaflet No. 137 containing particulars and illustrations of the Ediswan "Paragon" fan motors, 1900 pattern. These fan motors are made in three different types—ceiling, wall or partition, desk or table. All parts are interchangeable. They are attractive in appearance, and require no attention after installation. Each type of fan is illustrated.

Anti-Friction Alloys.—Anti-Friction Alloys (Ltd.), 52, Queen-Victoria-street, London, E.C., have prepared a list of the items of their manufacture of special interest to tramway engineers. These goods include tram and motor car bearings, slide valves, &c.

Tall Buildings.—Messrs. Fairbanks & Co., of 16, Great Eastern-street, London, E.C., have issued an album of the leading prominent buildings of New York City. Copies of the album can be obtained post free. As there is some discussion at the present time in relation to the desirability of tall buildings, the Fairbanks Company think these illustrations may prove interesting.

Acetylene and Carbide of Calcium.—The Acetylene Illuminating Co., of 3, Victoria-street, London, S.W., have issued a pamphlet dealing with the manufacture of these supplies. The company claim that their experience with carbide of calcium and acetylene dates back from August, 1894. They were the first firm in Europe to erect electrical furnaces for the commercial manufacture of carbide. It is stated that now at least 100,000 H.P. are being utilised throughout the world for making carbide. As a matter of historical interest, it is stated that the chief credit of producing carbide of calcium economically on a large scale, and thus laying the foundation of a new and important industry, belongs to Mr. T. L. Willson, a Canadian, who began his experiments on a considerable scale in 1888.

Crossley Gas and Oil Engines.—Useful and instructive particulars relating to the gas and oil engines manufactured by Messrs. Crossley Bros. (Ltd.), of Openshaw, Manchester, are now ready. Many varieties of engines are described and very effectively illustrated. A single-cylinder high-speed gas engine for electric lighting shown on pp. 10 and 11 gives the idea of great strength and easy running. The machine shown is fitted with a heavy fly-wheel, out-end bearing, balanced cranks, &c, the standard engines being fitted with two flywheels. These machines are guaranteed to give safe working loads of 80 B H.P., 95 B.H.P., and 100 B.H.P. with coal gas. Several new patent vertical gas engines are shown for which it is claimed that the gas consumption has been greatly reduced. Double-cylinder engines of the newest designs made in sizes to give safe working loads of 135 B.H.P., 160 B.H.P. and 180 B.H.P., with ordinary gas are supplied. These engines are built on Crossley's new scavenging patent, and are fitted with heavy flywheels when used for electric lighting. The Crossley oil engines (illustrated) show several improvements, one a new design giving 21 B H.P. safe working load. Several new designs of high-speed electric light oil engines are also illustrated.

Exports of Electrical Apparatus and Material.—The following list gives official particulars of the exports of British manufactured electrical apparatus and material (including telegraph and telephone wire and material, but not including electrical instruments or machines, which are not separately specified) from June 27 to July 3, with the ports of destination :—

Africa—Alexandria, £62; Cape Town, £506; Durban, £959; East London, £9. *Argentina*—Buenos Ayres, £239 (including £85 telegraph material). *Australasia*—Albany, £137; Auckland, £81; Launceston, £360; Melbourne, £342 (telegraph cable); Port Darwin, £76 (telegraph material); Sydney, £661, *Azores*—£909 (telegraph material). *Belgium*—Brussels, £38; Ostend, £5. *Brazil*—Rio Janeiro, £189. *Canada*—Halifax, £625 (telegraph cable). *Canary Islands*—Teneriffe, £65. *Ceylon*—Colombo, £59. *Chili*—Valparaiso, £115. *Denmark*—Copenhagen, £1,380 (telegraph cable); *Germany*—Hamburg, £1,350 (telegraph material). *Gibraltar*, £61. *Holland*—Amsterdam, £185; Flushing, £19; Rotterdam, £50. *India*—Bombay, £110; Calcutta, £76; Madras, £685. *Norway*—Christiana, £82 (telegraph material). *Russia*—St. Petersburg, £700 (telegraph wire). *Spain*—Malaga, £35. *Straits Settlements*—Singapore, £36. *Sweden*—Stockholm, £279 (telegraph cable). Total £10,485, against £30,231 in the corresponding week last year (June 28 to July 4).

PATENT RECORD.

The following list of Applications for Patents and Specifications published has been compiled for this journal by MESSRS. J. C. CHAPMAN and Co, *Chartered Patent Agents, of 70, Chancery-lane, W.C., from whom any available information in connection with Patents, Designs, and Trade Marks may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned Applications are not open to public inspection until after the acceptance of the complete Specification. The names within parentheses are those of communicators of inventions. When complete specification accompanies application, an asterisk is affixed.*

April 14, 1900.

6,974. W. P. THOMPSON. Liverpool. An improved system or means for controlling or regulating electrical installations. (C. Coeper, Germany.)
6,981. C. B. KETLEY. Birmingham. Improvements in photographs.
7,031. H. H. LAKE. London. Improvements in electric clocks. (W. J. Dudley, United States.)*
7,034. C. B. KETLEY. Birmingham. Improvements in photographs and graphophones.

April 17, 1900.

7,062. C. RICCI. London. Variable speed gear for mechanically or electrically-propelled vehicles.
7,070. J. C. KNEALE and H. HARTLEY. London. Improvements relating to telephones.
7,084. A. J. BOULT. London. Improvements in or relating to electric motors. (O. H. and A. F. Pieper, United States.)*
7,098. S. H. SHORT. London. Improvements in or relating to multipolar electric machines.*
7,100. L. J. P. HOLLUB and H. MIGNAL. London. A new or improved device to fixing incandescence electric lamps.
7,106. J. M. MURPHY. London. Improvements in electric railway systems.*
7,108. F. R. SIMMS and R. BOSCH. London. Improvements in or connected with magneto-electric machines.*
7,109. R. VARLEY. London. Improvements in electro-magnetic coils.*
7,133. H. H. LAKE. London. Improvements in incandescence electric lamps. (S. D. Washburn and C. H. Tinkham, United States.)*

April 18, 1900.

7,155. J. NEWNS. Liverpool. Improvements in overhead electric tram and railway conductor, junctions and crossings.
7,157. A. MARR. Manchester. Improvements in and relating to telegraphic transmitting devices.
7,198. W. P. THOMPSON. London. Improvements in the method of producing complex chemical compounds by electrolysis with alternating currents. (Alf. Sinding-Larsen, Norway.)*
7,200. W. P. THOMPSON. Liverpool. Improvements in electric belts for the electric treatment of the human body. (M. A. McLaughlin)

April 19, 1900.

7,218. J. T. PEARSON. Burnley. Improvements in and relating to the application of electricity and/or magnetism to fibrous substances and fabrics and/or to machinery and apparatus or parts thereof employed in the preparation, manufacture and treatment of such substances and fabrics.
7,239. V. J. DELEBECQUE. London. Improvements relating to fusible cut-outs for electric circuits.
7,245. H. LEITNER. London. Improvements in the production of plates for secondary batteries.
7,246. H. LEITNER. London. An improved secondary battery.
7,272. H. BAKER. London. Improved connections for carbon electrodes.
7,285. R. C. PARSONS, R. BELFIELD and W. CHAPMAN. London. Improvements in or relating to electric railways operated on the conduit system.
7,287. L. HENNE and G. SCHÖNFELDER. Liverpool. Improvements in electric railways with underground conductors.

April 20, 1900.

7,314. R. C. SAYER. Bristol. Improvements in boiling and vaporising fluids by electricity.*
7,319. A. J. MARLEY and L. TURNER. London. Nubrit electric furniture polish and renovator.
7,320. A. THODE AND CO. London. Improved sound deadener for overhead conductors of electric railways and the like.
7,321. A. THODE AND CO. London. Improved electric rotating insulator.
7,322. W. E. IRISH. London. Incandescent electric lamp.
7,356. E. SCHATTNER and F. W. HARMER. London. Improvements in electrical incandescence lamps.
7,372. A. TRIBELHORN. London. An improved manufacture of electrodes.
7,373. W. LANGDON-DAVIES and A. SOAMES. London. Improvements in the formation of drum windings for dynamo-electric machines.

April 21, 1900.

7,392. A. LEHNER and A. VON DAUBER. Berlin. Electro motor of varying revolutions.*
7,393. A. PERAZZI. London. Electric and chemical apparatus for the scalp.
7,410. P. KÄSBAUER, M. HABERFELLNER, and O. LENCK. London. Improvements in regulators for electric arc lamps.*

April 23, 1900.

7,433. H. HIRST and J. H. COLLINGS. London. Improvements in joints for rods carrying electric lamps and other purposes.
7,434. H. HIRST and M. ZELLERMAYER. London. Improvements in connections for electrical cables and kindred purposes.
7,471. S. G. BROWN. London. Improvements in electric telegraphy.
7,483. I. TIMAR. London. Electric sweating mattress.*

April 24, 1900.

7,510. C. MILES. Bristol. Improvements in electrically-governed feeding and drinking appliance for animals, live stock, birds, and the like.
7,511. C. MILES. Bristol. Improvements in electrical time checking and registering apparatus.
7,513. S. COWPER-COLES. London. Improvements in secondary batteries.
7,537. A. N. PETIT. London. Improvements in machines for reproducing phonographs and similar records.*
7,547. W. E. IRISH. London. Incandescent electric lamp.
7,561. THE BRITISH THOMSON-HOUSTON CO. (LTD.). London. Improvements in maximum electric meters. (H. O. Westendrap, United States.)*
7,562. THE BRITISH THOMSON-HOUSTON CO. (LTD.). London. Improvements in third rail insulators for electric railways. (E. W. Rice, jun., United States.)*
7,567. H. P. BROWN. London. Improvements in electric bonds for electrically connecting the meeting ends of two contiguous electric conductors.*
7,581. E. A. HAWTHORNE. London. Improvements in phonographs and graphophones.*
7,586. G. B. CRUICKSHANK, H. R. S. COLEMAN, and P. CRUICKSHANK. Birmingham. Improvements in apparatus for electro-plating.
7,593. J. G. S. LEE. London. Improvements in contacts for incandescent electric lamp holders, electric switches, and so forth.
7,594. W. P. THOMPSON. Liverpool. Improvements in graphophones. (G. L. Hogan, United States.)*
7,606. C. A. LINDSTROM, J. HEWITT, and T. HEWITT. London. Improvements in electrical controlling switches.*
7,608. E. RASCH. London. Improvements connected with the production of electric light.
7,609. P. SCHARF. London. Improvements in glow lamps for high-tension currents.

April 25, 1900.

7,639. S. H. HOLDEN and CHAMBERLAIN AND HOOKHAM (LTD.). London. Improvements in dynamo-electric machines.
7,645. S. E. FEDDEN and W. JAMIESON. Greenock. Improvements in distribution of polyphase currents.
7,648. F. M. LONG and E. SCHATTNER. London. Improvements in electric arc lamps.
7,657. W. T. BURBEY. London. Improvements in and connected with cord grips for electric lamp holders, ceiling roses, and the like.
7,675. H. H. LAKE. London. Improvements in electrical time-distributing apparatus. (H. Cuenod, Switzerland.)

April 26, 1900.

7,695. S. S. GALSWORTHY. London. Improvements in wall plugs for electric lighting and heating.*
7,712. M. OLIVER. Sheffield. Improvement in electric billiard-marking time check relating to the balls being out of play at the end of a stated time.
7,721. P. LUDWIG. Germany. Adjustable bracket for electric lighting.
7,725. A. G. NESFIELD. London. Improvements in or connected with electric accumulators or storage batteries.

SPECIFICATIONS PUBLISHED.

NOTE.—All Specifications can now be obtained at the uniform price of 8d. each.

1899.

25,450. BRITISH THOMSON-HOUSTON CO. (LTD.) (Potter). Systems of electric train control.
25,751. BRITISH THOMSON-HOUSTON CO. (LTD.) (Van Slyck). Electric time switches.

1900.

135 NELLES. Device for renovating phonograph record cylinders and the like.
1,464. MURPHY. Surface-contact electric railway systems.
1,886. NEWTON. (Rabbidge.) Arrangement of switching appliances for use with telephones.
2,150. DALLAIRE. Telephone transmitters.
2,356. SIEMENS BROS. AND CO. (LTD.) (Siemens and Halske Aktien Gesellschaft.) Apparatus for regulating the electric lights on theatre stages.
2,742. MAYLINDER. Apparatus for firing submarine mines by means of Hertzian radiations.
2,797. POPOV. Coherers for telephonic and telegraphic signalling.
2,842. BROOKES. (Woodman and Fiske.) Thermostatic circuit controlling apparatus.
3,105. REED, REED and FARRAR. Systems of electrical distribution and safety apparatus therefor.
3,106. REED, REED and FARRAR. Automatic electric circuit breaker.
3,107. REED, REED and FARRAR. Isolated alternating low tension systems of electric distribution.
3,361. HATHAWAY. Manufacture of secondary batteries.
3,371. PORTER. Electric heaters and switches thereof.
3,545. FRANK. Insulation of electrical conductors.
3,731. SANDER. Manufacture of electrically-conducting material.
3,753. COMMELIN and VIAN. Electrical secondary batteries.
4,052. JOHNSON (American Graphophone Co.). Manufacture of sound records.
4,081. SHEBLE. Phonograph or graphophone instruments.
4,262. NEWTON (Knickerbocker Trust Co.). Electric batteries and in the method of making electrodes therefor.
4,365. SHOOLBRED. Translucent reflectors for incandescent electric lamps.
4,508. GARL. Electric signalling systems for railways.

COMPANIES' MEETINGS AND REPORTS.

United River Plate Telephone Co. (Ltd.).

The fourteenth ordinary general meeting of this Company was held on Tuesday, under the presidency of J. IRVING COURTENAY, Esq.

The SECRETARY (Mr. E M. Reiss) having read the notice calling the meeting, and the report of the Directors having been taken as read,

The CHAIRMAN said: The continued improvement, Gentlemen, anticipated at our last meeting has been fully realised during our financial year. The fluctuations in the gold premium have been slight, the Government scheme for maintaining the minimum gold premium at 127·30 having, so far, met with a measure of success; the average rate for the year ending last March was 17 points lower than the average for the previous corresponding period, while the closing rate at the same date, when our balances were converted, was five points higher than in 1899. The number of our subscribers is now approaching 9,000, the increase being 50 per cent. greater than during the previous year. The new central office building was completed last December, and satisfactory arrangements have been made for renting the portions not required by the Company. Substantial progress has been made with the important work of laying underground plant. It is considered essential, to the Company's best interests to extend the system of subways as rapidly and to as large an extent as possible. Turning to the balance-sheet, the large addition for capital outlay of £23,154 is due to the expenditure on underground plant, switchboards, &c., referred to when I last addressed you. The item of conversion of the old 7 per cent. debentures has disappeared, the balance of £5,504. 6s. 8d., having been written off the depreciation fund. Sundry debtors, £8,222, are some £1,600 more, owing chiefly to advance payments on materials ordered which are carrying interest. Investments amount to a higher figure, real estate being augmented by the further expenditure on new central office properties in Buenos Ayres, and our other investments, being securities at cost, have been increased by sums invested temporarily until required for capital outlay. The stock of instruments and materials in the River Plate, standing this year at £1,000 more than it did last year, consist almost entirely of new material. The remaining items of bills receivable and cash at bankers, in hand, and at call, make the total cash balance £34,406. The debit side shows our subscribed share capital increased by the issue of preference shares by £83,195; the debenture stock remains at £179,947. Sundry creditors, £5,387, are about £500 less, and subscriptions in advance are also slightly below the figure at the corresponding date. The reserve fund is now increased to £40,000, and the depreciation fund stands at £3,495. On the credit side our gross revenue in the River Plate is this year in six figures—a fact, I think, we may justly be proud of, the amount (£101,169) showing an increase of nearly £16,000 over last year. Expenses, on the other side of the account, maintenance charges in the River Plate, (£45,042), show an increase of only £3,000. London expenses show an increase of £2,353, which includes the expenses of the preference share issue. This leaves the balance of profit for the year £35,179, after deducting debenture interest and dividends paid on our preference and ordinary shares at the end of December last, the latter amounting to £7,250; so that the total net profit for the year was £42,429 compared with £33,333 last year. The Board propose that £5,000 should be put to depreciation and £20,000 to reserve. After paying a further dividend on the ordinary shares of 4½ per cent., making a total return for the year of 7 per cent., there remains £5,019 to carry forward. I will now deal with the important subject of capital expenditure. As indicated at our last annual meeting we must recognise the necessity of adding largely to our capital outlay in order to properly equip our telephone plant with the latest improvements and thus render it effective to meet not only the business already existing, but the continual increase in the future which we have every justification for expecting. Our overhead wires are already so numerous, and are of necessity so close together, that it becomes more and more difficult—it is almost impossible—to avoid induction, that great bane to good telephone service, and the obvious remedy is to have as extended an underground system as possible. A substantial beginning of this necessary work has already been made, but much remains to be done, and in order to provide for a scheme which shall at once be not only efficient but also economical, it is essential for the Directors to have the requisite capital at their command. It has therefore been decided to at once issue the balance of the preference share capital which was authorised last year. Of the authorised amount of £200,000, half was then offered to the public, with the result that £83,195 was subscribed. It is now intended to offer the remaining £116,805, and, in allotment, every consideration will of course be given to applications by existing shareholders. I now move the adoption of the report and accounts.

Mr. F. GREEN seconded the motion.

Mr. LEA-SMITH said he thought that the shareholders present ought not to allow a report such as that which had been presented to them on

Digitized by Google

that occasion by the Directors to pass in silence. He regarded the dividend as very good, but in his opinion the best part of the report was that in which the Directors dealt with the question of the reserve fund.

Mr. Frank W. Jones and Mr. George Cooper were re-elected Directors, and Messrs. Welton, Jones & Co. were reappointed auditors.

A vote of thanks to the Chairman and Directors was carried by acclamation, and the proceedings then terminated.

Blackheath and Greenwich District Electric Light Co. (Ltd.)

A meeting of this company was held on Tuesday for the purpose of increasing the capital of the company by the creation of 150,000 new preference shares of £1 each, holding special rights and privileges, and also to authorise the board to create and issue 4½ per cent. debenture stock of the nominal amount of £120,000, such stock to have the right of conversion into fully-paid 7 per cent. preference shares of the same amount at any time after July 1, 1905. Sir JOHN WILLOX, M.P., presided.

The SECRETARY (Mr. S. H. Webster) having read the notice calling the meeting,

The CHAIRMAN said when he last addressed the shareholders the company had not commenced the supply of electricity from its own works, but now they had commenced their supply. They had already secured a good many orders both for light and power. When they began their own supply in February the number of lamps connected was equivalent to 5,900 8 c.p., and at the present time they had 10,000 lamps connected. As the longer nights approached that rate of progress would doubtless be accelerated. They were also supplying a considerable amount of energy to industrial works, and had completed contracts for still larger supplies of power for manufacturing purposes. The total expenditure to date was £128,000, and there were other charges to be brought in. The present available resources of the company were not sufficient to meet those liabilities; and there was another reason for new capital—namely, the extension of the company's area of supply, which they had obtained powers for in order to hold it, as another company had made application. That would enlarge their area to 15 square miles, with 60 miles of roads. The amount of their requirements the board estimated at £100,000. The proposed new debenture stock would be repayable in 1931, and would be redeemable at the option of the company at 105 after it had run for 10 years. But the debenture holders were also allowed an option. Under certain restrictions they might convert their debenture stock into an equivalent amount of 7 per cent. cumulative preference shares, but the option of making such conversion practically attached only to a period of five years. Allotments of the stock would be made to the shareholders in priority of other applicants. Some shareholders had assumed, with natural alarm, that the directors proposed to issue both mortgage debentures and preference shares. They had no such intention. What they proposed was to issue £100,000 of debenture stock, and if the debentures were converted into preference shares, such debentures would *ipso facto* be cancelled. He concluded by moving the approval of the resolutions.

Mr. H. W. BOWDEN seconded the motion.

After some discussion,

The CHAIRMAN gave a pledge that the board would issue no preference shares, except for the purpose of exchange, without first coming to the shareholders.

The resolutions were then agreed to, and the meeting terminated.

West African Telegraph Co. (Ltd.).

The fifteenth ordinary general meeting of this Company was held on Friday last under the presidency of the MOST HON. the MARQUIS OF TWEEDDALE, K.T.

Mr. JOHN CAMBROOK (the Secretary) read the notice calling the meeting, as also the minutes of the last ordinary general meeting, and the report of the Directors and statement of accounts were taken as read.
